# INTRODUCTION

## TO THE ARTICLES RELATING TO ORGANIC CHEMISTRY.

In the present volume the nomenclature is the same as that adopted in the first volume. It has been explained in the Introduction to that volume, pp. viii-xiv. Thus, to take a single instance, the products of condensation between hydrazines and ketonic compounds are still called hydrazides, although Emil Fischer has, since the publication of the last volume, changed their name to hydrazones. • Even supposing the latter name to be preferable, its abrupt introduction would greatly confuse the nomenclature by depriving it of uniformity.

• Since the publication of the first volume I have been assisted in the work of reading and making abstracts of original memoirs by Drs. T. A. Lawson and Samuel Rideal, Messrs. J. Wilkie, J. T. Noonan, V. H. Veley, G. N. Huntly, S. H. Collins, Dr. G. McGowan, and Mr. D. A. Louis. I have also been ably assisted by Mr. Arthur G. Green in the work of revising the proof sheets. I have great pleasure in thanking these gentlemen for the energetic and efficient manner in which they have carried out their share of the work.

H. FORSTER MORLEY.

### Nomenclature of Ring Formulae.

#### Hydrocarbons.

#### Nitrogen ring compounds.

## INTRODUCTION.

## Nitrogen ring compounds—cont.

## Oxygen ring compounds.

## Sulphur ring compounds.

In many of the above formulæ the exact structure is not known; alternative ways of writing some of them will be found in vol. i. p. xii.

## INITIALS OF SPECIAL CONTRIBUTORS.

- H. B. HARRY BAKER, Esq., F.C.S., *Chemist to the Aluminium Company, Oldbury.*  
Contributes CRYSTALLISATION.
- F. W. C. FRANK WIGGLESWORTH CLARKE, Esq., B.Sc., *Chief Chemist, United States Geological Survey.* Contributes ELEMENTS.
- I. F. MISS MIRA FREUND, *Lecturer in Chemistry, Newnham College, Cambridge.* Contributes DENSITIES, RELATIVE.
- A. G. G. ARTHUR G. GREEN, Esq., F.I.C., *Research Chemist to the Atlas Works, Hackney Wick.* Contributes INDIGO.
- D. H. DAVID HOWARD, Esq. Contributes CINCHONA BARK.
- J. J. H. J. J. HOOD, Esq., D.Sc. Contributes EARTHS.
- W. D. H. W. D. HALLIBURTON, M.D., B.Sc., *Assistant Professor of Physiology at University College, London.* Contributes HÆMOGLOBIN.
- R. J. FRANCIS R. JAPP, M.A., Ph.D., F.R.S., *Assistant Professor of Chemistry at the Normal School of Science, South Kensington.* Contributes GLYOXALINES, HYDRAZINES, and HYDRAZONES.
- G. M. GEORGE MCGOWAN, Ph.D., F.R.S.E., *Demonstrator in Chemistry at University College of North Wales, Bangor.* Contributes CHOLESTERIN.
- F. W. R. F. W. RUDLER, F.G.S., *Curator of the Museum of Practical Geology, London.* Contributes GEOLOGICAL CHEMISTRY.
- I. R. IRA REMSEN, Ph.D., *Professor of Chemistry in Johns Hopkins University, Baltimore.* Contributes EQUIVALENCY and FORMULÆ.
- S. R. SAMUEL RIDEAL, D.Sc., *Lecturer on Chemistry at St. George's Hospital Medical School.* Contributes FERMENTATION.
- E. S. DR. EDWARD SCHUNCK, Ph.D., F.R.S., *Manchester.* Contributes CHLOROPHYLL.
- A. S. ALFRED SENIER, M.D., Ph.D. Contributes CYANIC ACIDS.
- C. O'S. C. O'SULLIVAN, F.R.S., *Barton-on-Trent.* Contributes DEXTRIN.
- J. J. T. J. J. THOMSON, M.A., F.R.S., *Professor of Experimental Physics in the University of Cambridge.* Contributes EQUILIBRIUM, CHEMICAL.
- M. R. B. THRELFALL, M.A., *Professor of Physics in the University of Sydney, N.S.W.* Contributes DISSOCIATION and EXPLOSION.
- T. E. W. T. E. THORPE, Ph.D., F.R.S., *Professor of Chemistry at the Royal School of Mines.* Contributes COMBUSTION and FLAME.
- V. H. V. V. H. VELEY, M.A., *Public Lecturer and Demonstrator in the University of Oxford.* Contributes FORMIC ACID.

Articles by Mr. MUIR are initialed M. M. P. M.

Unsigned ARTICLES are by Dr. MORLEY.

## II. TERMS AND QUANTITIES, &amp;c., FREQUENTLY USED.

<i>Aq.</i>	Water; e.g. NaOH <i>Aq</i> means an aqueous solution of caustic soda.
<i>aq.</i>	18 parts by weight of water.
<i>A'</i>	Residues of mono-, di-, and tri-basic acids. Thus, in describing the salts of a monobasic acid $\text{NaA'}$ , $\text{CaA'}$ , $\text{AlA'}$ , may be written, $\text{HA'}$ standing for the acid. For a dibasic acid we should write $\text{NaA''}$ , $\text{CaA''}$ , $\text{AlA''}$ , &c.
<i>A''</i>	
<i>A'''</i>	
<i>B' B''</i> etc.	Stand for bases of the ammonia type, in describing their salts. Thus the hydrochloride would be $\text{B'HCl}$ or $\text{B''}2\text{HCl}$ , according as the base is monacid or diacid, &c.
<i>conc.</i>	Concentrated.
<i>dil.</i>	Dilute.
<i>g.</i>	gram.
<i>mgm.</i>	milligram.
<i>mm.</i>	millimetre.
<i>mol.</i>	molecule.
<i>oil.</i>	liquid, nearly, or quite, insoluble in water.
<i>pp.</i>	precipitate.
<i>to ppt.</i>	to precipitate.
<i>ppg.</i>	precipitating.
<i>ppd.</i>	precipitated.

H.C. p. . . .	The same, under constant pressure . . .	
H.F. . . . .	Quantity of heat, in gram-units, produced during the formation of the mass of a solid or liquid body represented by its formula, taken in grams, from the masses of its constituent elements expressed by their formula, taken in grams . . .	
H.F. v. . . .	Heat of formation of a gram-molecule of a gaseous compound from the gram-molecules of its elements under constant volume . . .	
H.F. p. . . .	The same, under constant pressure . . .	
H.V. . . . .	Heat of vaporisation of a liquid, i.e. gram-units of heat required to change a gram-molecule of the liquid compound at B. P. into gas at same temperature and pressure . . .	
T.C. . . . .	Thermal conductivity (unit to be stated) . . .	
S.V. . . . .	Specific volume; or the molecular weight of a gaseous compound divided by the S.G. of the liquid compound at its boiling-point compared with water at 4° . . .	
S.V.S. . . . .	Specific volume of a solid; or the mass of the solid expressed by its formula, taken in grams, divided by its S.G. . . .	
E.C. . . . .	Electrical conductivity (the unit is stated in each case) . . .	
C.E. (10° to 20°) . .	Coefficient of expansion (between 10° and 20°) . . .	
S. . . . .	Solubility in water of a gas = volume dissolved by 1 volume of water . . .	
S. (alcohol) . .	" " " " " of a liquid or solid = number of grms. dissolved by 100 grms. of water. In both cases the temperature is stated . . .	
Index . . . .	Index of refraction for hydrogen lines . . .	
R <sub>D</sub> . . . . .	" " " " " sodium " " " D, &c. . .	
R <sub>D</sub> . . . . .	Molecular refraction for sodium light, i.e. index of refraction for line D minus one, multiplied by molecular weight, and divided by S.G. at 15° compared with water at 0° . . .	
R <sub>D</sub> . . . . .	The same; S.G. being determined at 15°-20° and referred to water at 4° . . .	
R <sub>∞</sub> . . . . .	The same for line of infinite wave-length, index being determined by Cauchy's formula (Brühl's R <sub>A</sub> ) . . .	
[α] <sub>D</sub> . . . . .	Specific rotation for sodium light . . .	
[α] <sub>D</sub> . . . . .	" " " " " neutral tint. $[\alpha] = \frac{100}{p} \times \frac{a}{d}$ . a = observed rotation for 100 min. of liquid. d = S.G. of liquid. p = no. of grammes of active substance in 100 grammes of liquid . . .	

\* Denotes that the formula to which it is affixed has not been determined by analysis. But it by no means follows that formulae without this mark are those of analysed compounds.

All temperatures are given in degrees Centigrade unless when specially stated otherwise.

Wave-lengths are given in  $10^{-7}$  mm.

Formulae, when used instead of names of substances, have a qualitative meaning only.

Thomson's notation is used in thermochemical data.

# DICTIONARY OF CHEMISTRY

**CHENOCHOLIC ACID**  $C_{27}H_{44}O_6$ . Formed by boiling **taurochenocholic acid**, from goose-bile, with baryta-water (Heintz a. Wislicenus, *P.* 108, 547). Amorphous mass (from alcohol or ether), insol. water. Gives **Stattenkofer's** reaction with  $H_2SO_4$  and sugar. Insol. cold  $KOH$  aq, but dissolves on warming, forming a solution that is ppd. by  $BaCl_2$  and  $CaCl_2$ .— $BaA'$  (dried).

**CHENOPODINE**  $C_8H_9NO$ . This base, which occurs in white goosefoot (*Chenopodium album*) (Reinsch, *N. J. P.* 20, 268; 21, 132; 27, 193; *J. pr.* [2] 22, 188), is probably leucine (Gorup-Besanoz, *B.* 7, 147).

● **CHICA**. A red dye obtained from the leaves of *Bignonia Chica* growing in South America. The colouring-matter may be extracted by alcohol. It is insol. ether and  $Na_2CO_3$  aq, but sol.  $NaOH$  aq. Chromic acid oxidises it to anisic acid (Erdmann, *J. pr.* 71, 198).

● **CHICORY**. The blue blossoms of *Cichorium Intybus* contain a glucoside  $C_{20}H_{31}O_{14}$  aq [215°-220°], which may be extracted by dilute alcohol. It crystallises from water, in which it is slightly soluble, in needles. Aqueous alkalis and alkaline carbonates form yellow solutions. Boiling dilute acids split it up into glucose and  $C_{12}H_{21}O_9$  [250°-255°], which also occurs in the blossoms. This forms needles, v. sl. sol. boiling water, coloured dark green by  $Fe_2Cl_6$  (Nietzki, *J.* 1876, 351; *Ar. Ph.* [3] 8, 327).

**CHICLE ALBAN**  $C_{10}H_{16}O$ . [145°]. S. (alcohol of S.G. .82) .66 at 14°. Obtained by extracting chicle gum (Mexican rubber juice), from *Chrysophyllum glycyplacum*, with weak alcohol (Prochazka a. Endemann, *A. C. J.* 1, 50). The mother-liquor deposits chicle fluavil  $C_{10}H_{16}O$  (?); S. (alcohol of S.G. .82) 2.6 at 13.5°. The residue of the gum, after extracting with alcohol, contains two terpenes and arabin.

● **CHIN**. Substances beginning with **CHIN** will be described under the alternative names which begin with **QUIN**. Thus Chinidine, Chinone, and Chinoline are described as **QUINIDINE**, **QUINONE**, and **QUINOLINE**.

**CHIRATIN**  $C_{20}H_{31}O_{10}$ . Extracted, by dilute alcohol from the stalks of *Ophelia chirata* (Höhn, *Ar. Ph.* [2] 139, 213). Resinous mass, decomposed by hot dilute  $HCl$  into ophelic acid and morpous chirapogenin  $C_{12}H_{20}O_4$ .

**CHITENIDINE**  $C_{11}H_{15}NO_5$ . Formed by oxidation of quinidine with  $KMnO_4$ . Thin plates (containing 2 aq). Sol. alkalis and hot water, sl. sol. alcohol.— $B''H_2SO_4$  3 aq; white prisms.— $B''H_2Cl.PtCl_3$  3 aq; large orange-red needles Forst a. Böhringer, *B.* 15, 1659).

**CHITENINE**  $C_{11}H_{15}N_2O_5$ . Prepared by oxidation of quinine with  $KMnO_4$ . White prisms Vol. II.

(containing 4 aq). Insol. alcohol and ether, sl. sol. water. Very weak base.— $B.(H_2SO_4)$  15 aq; fine needles.— $BH_2Cl_2.PtCl_3$  3 aq (Skraup, *B.* 12, 1104).

**CHITIN** v. **PROTEIDS**, Appendix C.  
**CHLORAL**  $C_2H_3ClO$  i.e.  $CCl_2CHO$ . *Tri-chloro-acetic aldehyde*. Mol. w. 147.5. [c. -75°] (Werthelot, *B.* [2] 23, 3). (98° cor.) (Perkin); (97.2°) (Thorpe, *C. J.* 37, 191). V.D. 5.13. S.G.  $\frac{1}{4}$  1.5202 (Perkin, *C. J.* 51, 308);  $\frac{1}{2}$  1.5121 (Brühl, *A.* 203, 11);  $\frac{3}{4}$  1.5417 (Pa.). C.E. (0°-10°) .001123; (0°-100°) .001295 (Laura Passavant, *C. J.* 39, 53).  $\mu_D$  1.4623.  $R_D$  43.06. M.M. 6.591 at 16° (Perkin). S.V. 107.4.

*Formation*.—1. By the action of chlorine on aqueous aldehyde (Pinner, *B.* 4, 256; Wurtz a. Vogt, *Z.* 1871, 679).—2. From tri-chloro-acetal and  $H_2SO_4$  at 150° (Paterno, *A.* 150, 256; *Z.* [2] 4, 733).—3. By distilling starch or sugar with  $HCl$  and  $MnO_2$  (Städeler, *A.* 61, 101).—4. By distilling tetra-chloro-ether,  $CCl_4.CHCl(OEt)$ , with  $H_2SO_4$  (W. a. V.).

*Preparation*.—Chlorine gas is passed into absolute alcohol, which must be cooled at first, but afterwards may be heated gradually to boiling. The crystalline chloral alcoholate formed is decomposed by shaking with  $H_2SO_4$ , and the liquid chloral rectified (Liebig, *A.* 1, 189; Dumas, *A. Ch.* [2] 56, 126; Müller a. Paul, *B.* 2, 541; Thomsen, *Z.* [2] 6, 156; Roussin, *Z.* [2] 6, 96; Personne, *C. R.* 69, 1363; Paul, *P.* [3] 1, 621; *C. J.* 24, 134). By-products are ethylidene chloride, ethylene chloride, and chloro-ethylene chloride (115°). The chlorination is promoted by the presence of 5 p.c.  $FeCl_3$  (Page, *D. P. J.* 252, 343. V. also **CHLORAL HYDRATE**).

*Theory of the process*.—Chlorine oxidises alcohol to aldehyde, this combines with alcohol forming acetal  $CH_3CH(OEt)_2$ , which is then converted into tri-chloro-acetal  $CCl_2CH(OEt)_2$ , which is saponified by the  $HCl$  formed in the previous reactions:  $CCl_2CH(OEt)_2 + HCl = CCl_2CH(OH)(OEt) + EtCl$  (Lieben, *C. R.* 44, 1349; *B.* 3, 910). Wurtz (*C. R.* 74, 777) considers that chloro-ether is first formed, thus:  $CH_3CHO + HOEt + HCl = H_2O + CH_3CHCl(OEt)$ , and this is then converted into tetra-chloro-ether  $CCl_2CHCl(OEt)$ , which is converted by alcohol into tri-chloro-acetal  $CCl_2CH(OEt)_2$ , which is then decomposed by  $HCl$  as above.

*Estimation*.—By shaking with standard  $NaOH$  and determining the amount of alkali neutralised.

*Properties*.—A liquid with odour resembling aldehyde. It solidifies when shaken with a little water, forming so-called chloral hydrate, but it dissolves in much water. It reduces ammoniac-

cal silver nitrate with formation of a mirror. It is not affected by distillation over quicklime or BaO as long as the oxide is covered by the liquid. It combines with  $\text{NH}_3$ . When introduced into the blood it is split up into chloroform and formic acid (Lieblich; Personne, *C. R.* 69, 979; Byasson, *C. R.* 72, 742; Arloing, *C. R.* 83, 245, 526; cf. Thomaszewicz, *Pf.* 9, 35). Tanret supposed that its physiological action was due to the liberation of CO in the blood (*J. Ph.* [4] 29, 355). Some of the chloral passes into the urine as  $\alpha$ -chloro-lactic acid  $\text{C}_2\text{H}_4\text{ClO}_2$ .

**Reactions.**—1. Split up at once by NaOH into chloroform and sodium formate, thus:

Alcoholic KOH and NaOEt act similarly, forming formic ether and chloroform (Kekulé, *A.* 119, 187).

2. Zn and HCl reduce it to aldehyde (Personne, *A.* 157, 113; *C. R.* 71, 227). Zinc-dust and water reduce it, on heating, to  $\text{CH}_3\text{CH}_2\text{Cl}$  and  $\text{CH}_3\text{Cl}$  (Cotton, *Bl.* [2] 42, 622).—3. Fuming  $\text{HNO}_3$  oxidises it to tri-chloro-acetic acid.  $\text{CrO}_3$  or  $\text{HgO}$  gives CO and  $\text{CO}_2$ .  $\text{KMnO}_4$  gives  $\text{CO}_2$ , chloroform, oxygen, and chlorine (Cotton, *Bl.* [2] 43, 420).

4. Chlorine in sunlight forms  $\text{CCl}_3\text{H}$ , hydric chloride, and  $\text{COCl}_2$  (Gautier, *Bl.* [2] 45, 86; *C. R.* 101, 1161).—5. Bromine forms  $\text{CCl}_2\text{COBr}$ ,  $\text{CCl}_2\text{Br}$ , CO, and HBr (Ogilaloro, *B.* 7, 1461).—6. PCl<sub>5</sub> forms  $\text{CCl}_2\text{CCl}_2\text{H}$  (Paterno, *G.* 1, 590; *Z.* [2] 5, 245).—7. PCl<sub>5</sub>Br<sub>2</sub> forms  $\text{CCl}_2\text{CBr}_2\text{H}$ .—8.  $\text{H}_2\text{SO}_4$  forms chloralide crystals (*q. v.*). Fuming  $\text{H}_2\text{SO}_4$  forms a crystalline compound (*v. infra*).—9. KIaq forms iodine and chloroform. 10.  $\text{AlCl}_3$  forms parachloral (240°) and  $\text{C}_2\text{Cl}_4$  (Combes, *A. Ch.* [6] 12, 298).—11.  $\text{P}_2\text{S}_5$  forms  $\text{CHCl}_3$  (88°) (Paterno, *O.* 3, 538). 12. Aniline reacts violently forming tri-chloro-ethylidene-di-phenyl-di-amine  $\text{CCl}_3\text{CH}(\text{NHPh})_2$  [101°] (Wallach, *B.* 5, 251).—13. Acetamide combines forming  $\text{CCl}_3\text{CH}(\text{OH})(\text{NHAc})$  (*v. CHLORALAMMONIA*).—14. Acetonitrile forms  $\text{CCl}_3\text{CH}(\text{NHAc})_2$  (Hübner, *B.* 6, 109; *Z.* 1871, 712; Hepp, *B.* 10, 1651); needles (from HOAc).—15. Heated with syrupy lactic acid at 160° chloral forms tri-chloro-ethylidene mono-lactate:

This body may also be got by dissolving chloral hydrate (1 pt.) in syrupy lactic acid, and adding  $\text{H}_2\text{SO}_4$  (1 pt.) (M. Nencki, *J. pr.* 125, 239). In a similar way, tri-chloro-lactic acid heated with chloral forms chloralide (*q. v.*); tri-bromo-lactic acid forms tri-chloro-ethylidene tri-bromo-lactate:

[124°]; while mandelic acid produces

$\text{C}_6\text{H}_5\text{CH}(\text{CO}_2\text{O})\text{CH}_2\text{CCl}_3$  [82°].—16. When mixed with benzene (1 mol.) and concentrated sulphuric acid, di-phenyl-tri-chloro-ethane  $\text{CCl}_3\text{CH}(\text{C}_6\text{H}_5)_2$  is formed (Goldschmidt, *B.* 6, 985). Bromo- and chloro-benzene and toluene act similarly (Zaidler, *B.* 7, 1180; Fischer, *M.* 7, 1191).—17. By acting on benzene with chloral in the presence of aluminium chloride a liquid is obtained having the formula  $\text{C}_6\text{H}_5\text{CCl}_2\text{COH.HCl}$  which by oxidation forms the acid  $\text{C}_6\text{H}_5\text{CCl}_2\text{COOH}$  (Combes, *C. R.* 98, 678; *Bl.* [2] 41, 332).—18. Zinc methide (1 mol.) followed by water forms  $\text{CCl}_3\text{CH}(\text{OH})\text{CH}_3$ . Excess of  $\text{ZnMe}_2$  followed by water forms  $(\text{CH}_3)_2\text{CH.CMe}_2\text{OH}$ .—19. Zinc ethide followed by water forms tri-chloro-ethyl alcohol  $\text{CCl}_3\text{CH}_2\text{OH}$ .—20. Hydroxylamine forms chloro-glyoxim  $\text{C}_2\text{H}_3\text{ClN}_2\text{O}$ .

**Combinations.**—1. With water *v. Chloral hydrate*.

2. With alcohols *v. Chloral hydrate*.

3. With hydric sulphide:  $(\text{C}_2\text{Cl}_3\text{HO})_2\text{H}_2\text{S}$  [128°]. Formed by passing  $\text{H}_2\text{S}$  into a solution of chloral (Hagemann, *B.* 5, 154; Wyse, *B.* 7, 211; Paterno, *O.* 3, 533). Rhombohedra (from chloroform). Insol. water, sol. alcohol and ether. Decomposed by heat. With PCl<sub>5</sub> it gives  $\text{CCl}_3\text{CHCl}_2$ . Gives with AcCl a di-acetyl derivative [78°].

4. With phosphuretted hydrogen:  $(\text{CCl}_3\text{CHO})_2\text{PH}_3$  [143°]. From chloral (3 g.) and  $\text{PH}_3$  (2 g.). Small prisms (from ether). Decomposed by conc. NaOH into formate, hypophosphite, and hydrogen (Girard, *A. Ch.* [6] 2, 43).

5. With mercaptan:  $\text{C}_2\text{Cl}_3\text{HO.HS.Et}$ . Crystalline.

6. With acetyl chloride:  $\text{CCl}_3\text{CHCl}(\text{OAc})$  (*c.* 187°). S.G. 1.1476 (V. Meyer, *B.* 3, 445; *A.* 171, 67; cf. Curie a. Millet, *C. R.* 83, 745).

7. With acetic anhydride:  $\text{CCl}_3\text{CH}(\text{OAc})_2$  (222°). S.G. 1.1422. *Oil*.

8. With ethylamine:  $\text{CCl}_3\text{CH}(\text{OH})\text{NH.Et}$ . On distillation this forms  $\text{CHCl}_3$  and ethyl-formamide  $\text{H.CO.NH.Et}$ .

9. With fuming sulphuric acid:  $(\text{C}_2\text{Cl}_3\text{HO})_2\text{SO}_3.2\text{H}_2\text{SO}_4$  [70°]. Chloral (1 pt.) is mixed with fuming sulphuric acid (5 pts.). The product is washed with cold water and crystallised from ether (Grabowski, *B.* 6, 225, 1070). A mixture of chloral with an equal volume of fuming sulphuric acid forms large crystals of  $(\text{CCl}_3\text{CHO})_2\text{H}_2\text{S}_2\text{O}_7$ .

10. With alkaline bisulphites:  $\text{C}_2\text{Cl}_3\text{HO.KHSO}_3$  (Städeler, *A.* 106, 258; Rathke, *A.* 161, 154). This compound is also formed when  $\text{K}_2\text{SO}_3$  is used, but if the solution be heated to 80° ( $\text{SO}_3\text{K}$ )  $\text{CH}_3\text{CH}(\text{O})\text{KHSO}_3$  and crystallises out, while the mother-liquor contains  $\text{C}_2\text{H}_5\text{CH}(\text{O})\text{K}_2\text{S}_2\text{O}_7$ .

11. With hydrogen cyanide:  $\text{CCl}_3\text{CH}(\text{OH})\text{CN}$ . Tri-chloro-lacto-nitrile. [61°]. (*c.* 210°). Prepared by the action of anhydrous prussic acid at 120° upon chloral (Hagemann, *B.* 5, 151) or by boiling chloral with strong prussic acid (Bischoff a. Pinner, *B.* 5, 113; *A.* 179, 77). Trimetric plates (from  $\text{CS}_2$ ). Saponified by HCl forming tri-chloro-lactic acid. Saponified by KOH forming potassium formate and cyanide and chloroform. With urea it forms  $\text{CCl}_3\text{CH}(\text{NH.CO.NH}_2)_2$  (Pinner, *B.* 20, 2345). Acetyl derivative:  $\text{CCl}_3\text{CH}(\text{OAc})\text{CN}$  [31°]. (208°). From acetic anhydride and the above (Pinner a. Fuchs,

B. 10, 1059). Rhombohedra. Insol. water, sol. alcohol. Conc.  $\text{H}_2\text{SO}_4$  in the cold forms  $\text{CCl}_3\text{CH}(\text{OAc})\text{CO.NH}_2$ .

12. Another compound with hydrogen cyanide ( $\text{CCl}_3\text{CHO} \cdot \text{CNH}_2$  [123°]. From conc. solutions of chloral and of KCN (Cecch, B. 9, 1620). Prisms (from ether or benzene). Insol. water. Alcoholic potash (or even alcohol alone) forms di-chloro-acetic ether. On distillation it splits up into chloral and chloralide (Wallach, B. 6, 114). Alcoholic, or dilute aqueous, solutions of KCN convert chloral into di-chloro-acetic acid (or ether).

13. With cyanic acid:  $(\text{C}_2\text{Cl}_3\text{HO})_2\text{CNOH}$  [c. 169°]. Formed by passing vapour of cyanic acid into chloral, boiling the product with HCl and crystallising the residue from ether. Small prisms (Bischoff, B. 5, 86).

14. With both cyanic and prussic acids,  $\text{C}_2\text{Cl}_3\text{HO} \cdot \text{CNH} \cdot \text{CNOH}$  [80°]. Prepared by pouring a solution of CNOH upon a mixture of solutions of chloral and KCN. Needles. Decomposed by hot water. Converted by ethylamine into  $\text{CCl}_3\text{CH}(\text{NEH})\text{CHO}$  [45°] (Cecch, B. 8, 1174; ), 1253; 10, 880).

15. With sodium acetate;  $\text{CCl}_3\text{CH}(\text{OAc})(\text{ONa})$ . Minute white crystals, decomposed by water and alcohol (Rebuffat, G. 17, 406).

16. With carbamic ether:  $\text{CCl}_3\text{CH}(\text{OH})\text{NH.CO.Et}$  [103°]. Flaky mass from ether-alcohol, formed by adding conc. HCl to a solution of carbamic ether in chloral (Bischoff, B. 7, 631). Resolved into its components by hot water or by heating at 100°.

17. With urea:  $\text{CCl}_3\text{CH}(\text{OH})\text{NH.CO.NH}_2$  [150°]. From chloral and a conc. aqueous solution of urea. Scales. Decomposed on melting into chloral and cyanuric acid. The compound ( $\text{CCl}_3\text{CH}(\text{OH})\text{NH.CO}$  [100°] is also formed, and differs from the preceding in being nearly insol. boiling water (Jacobsen, A. 157, 246).

18. With benzamidozime:  $\text{C}_6\text{H}_5\text{N}_2\text{Cl}_3\text{O}_2$  [135°]. White powder, insol. water, v. sol. alcohol and ether. Resolved by boiling dilute  $\text{H}_2\text{SO}_4$  into its constituents (Falcik, B. 19, 1481).

19. With hexamidozime:  $\text{C}_6\text{H}_{12}\text{N}_6\text{Cl}_3\text{O}_2$  [130°]. White pearly plates. Formed by heating the components together for a long time (Jacoby, B. 19, 1505).

20. With thio-benzamide:  $\text{CCl}_3\text{CH}(\text{OH})\text{NH.CS.C}_6\text{H}_5$  [104°]. From chloral and thio-benzamide (Spica, G. 16, 182). Rhomboidal prisms of alliaceous odour, sl. sol. water, sol. alcohol and ether.

Chloral-ammonia  $\text{CCl}_3\text{CH}(\text{OH})\text{NH}_2$  [64°]. Formed by passing  $\text{NH}_3$  into a solution of chloral in chloroform (Siedeler, A. 406, 253; Schiff, B. 10, 167). Insol. cold water, decomposed by hot water into  $\text{CHCl}_3$  and ammoniac formate (Personne, A. 157, 114). Boiling alcoholic KCN converts it into di-chloro-acetamide (R. Schiff, A. Spetale, G. 9, 338). With benzoic aldehyde it gives  $\text{CCl}_3\text{CH}(\text{OH})\text{N:CHPh}$  [130°], which crystallises from benzene in white leaflets, resolved by dilute acids into benzoic aldehyde, chloral, and  $\text{NH}_3$  (Schiff, G. 9, 436).

Acetyl derivative. —  $\text{CCl}_3\text{CH}(\text{OH})\text{NHAc}$ . Chloral-acetamide. [156°]. Formed by the action of acetyl chloride or acetic anhydride on the above or from chloral and acetamide. Tri-metric plates (from water). Insol. ether. De-

composed by heat into chloral and acetamide. Alcoholic KCN forms  $\text{C}_6\text{H}_5\text{Cl}_3\text{N}_2\text{O}_2$  [120°] (S. a. S.).

#### Di-acetyl derivative.

$\text{CCl}_3\text{CH}(\text{OAc})(\text{NHAc})$ . [118°]. Formed by the action of  $\text{ClAc}$  at 120° on the preceding. Decomposed by warm water into the preceding and acetic acid, the group (OAc) being unstable in presence of so much chlorine.

#### Dichloroacetyl derivative.

$\text{CCl}_3\text{CH}(\text{OH})\text{NH.CO.CHCl}_2$  [105°]. From chloral and di-chloro-acetamide (S. a. S.). Large prisms (from water).

#### Benzoyl derivative.

$\text{CCl}_3\text{CH}(\text{OH})\text{NH.Bz}$ . [151°]. From benzamide and chloral (Jacobsen, A. 157, 245) or by passing HCl into a mixture of chloral-hydrate and benzonitrile (Pinner a. Klein, B. 11, 10). Tables (from alcohol). Alcoholic KCN forms a compound  $\text{C}_6\text{H}_5\text{Cl}_3\text{N}_2\text{O}$  [131°], which separates in small crystals from ether (S. a. S.).

Chloral hydrate  $\text{C}_2\text{H}_3\text{Cl}_3\text{O}_2$  i.e.  $\text{CCl}_3\text{CH}(\text{OH})_2$ . Tri-chloro-acetic ortho-aldehyde. Mol. w. 165.5. 57°. (97°). S.G.  $\frac{40}{4}$  1.6415 (Perkin, C. J. 51, 808);  $\frac{40}{4}$  1.575; S.G. (solid) 1.901. V.D. 2° (corresponding to a mixture of water and chloral). S. (in  $\text{CS}_2$ ) 2 at 15°; 20 at 46°.  $R_D$  47.94 (in a 33.2 p.c. aqueous solution) (Kanonnikoff, J. pr. [2] 31, 347). M.M. (used) 7.151 at 54.6°; (in aqueous solution) 7.02 at 14°.

Formation.—By direct union of chloral with water, absorption of heat taking place (Phipson, C. N. 25, 257).

#### Preparation.—Alcohol (400g. of 97 per cent.)

is poured upon crystallised ferric chloride (5g. of  $\text{FeCl}_3 \cdot 12\text{aq}$ ) and a large excess of chlorine is passed in. The product is distilled. The distillate contains chloral and chloral hydrate but not chloral alcoholate. After rectification the portion boiling between 94° and 97° is converted by water into chloral hydrate (525 g.) (Page, A. 225, 920; cf. Detsenyl, C. C. 1873, 767). Chloral hydrate may also be purified by crystallisation from  $\text{CS}_2$  (Plückiger, Z. 6, 432).

Properties.—Monoclinic plates, v. sol. water and alcohol. By shaking with conc.  $\text{H}_2\text{SO}_4$  it is at once converted into chloral. In doses of more than 5 g. it produces sleep (Liebreich, B. 2, 269). It is antiseptic, preventing putrefaction of proteids. The vapour of chloral hydrate is split up by heat into chloral and water; the dissociation is complete at 100° at the ordinary pressure, and even at 61° under a pressure of 9 mm. (Wurtz, C. R. 89, 190; cf. Moitessier a. Engel, C. R. 86, 971; Troost, C. R. 84, 708; 85, 32, 400; 100, 834; C. Ch. [5] 13, 411; 22, 155; Friedel, B. [2] 43, 56; C. R. 100, 891; Naumann, B. 9, 822).

\* The molecular magnetic rotation indicates that chloral hydrate exists as such in its aqueous solution. In amyloide solution it begins to dissociate between 30° and 40° (Perkin, C. J. 51, 808). Chloral hydrate differs from chloral in not exhibiting Schiff's test for aldehydes with rosaniline, and  $\text{SO}_2$  (V. Meyer a. Caro, B. 13, 2348).

Detection.—Chloral hydrate may be extracted by ether from its aqueous solution (e.g. urine) and the following tests may then be applied:

(a) Warming with alcoholic KOH and aniline gives (even with 0.00015g.) the disgusting odour of phenyl carbamine. (b) Warming at 50° with

conc. KOHAq and a little phenol gives a blue colour (with 0.0005g.). (c) After boiling with potash formic acid may be detected (with 0.0011g.). (d) Lime-water and H<sub>2</sub>S give a pink colour (with 0.00066g.) (Dragendorff a. Tiesenhause, *C. C.* 1886, 636). The valuation of chloral hydrate may be effected by decomposing it with ammonia, KOHAq, or, better, with H<sub>2</sub>SO<sub>4</sub> (Versmann, *Ph.* [3] 1, 701, 965; Wood, *Ph.* [3] 1, 763; cf. Müller, *Z.* [2] 7, 66; *C. J.* 24, 444; Paul, *Ph.* [5] 1, 621; *C. J.* 24, 134).

**Reactions.**—1. With KCy it forms di-chloro-acetic acid.—2. Heated with glycerin it forms chloroform, formic acid, and allyl formate (Byasson, *C. R.* 75, 1628).—3. Boiled with ammoniac acetate it forms chloralimide, CCl<sub>3</sub>CH<sub>2</sub>NH (Pirner a. Fuchs, *B.* 10, 1068).—4. Warmed with aqueous KHS deposits sulphur, and then crystals of C<sub>2</sub>H<sub>2</sub>Cl<sub>2</sub>O<sub>2</sub>S [97°] (Michaels, *B.* 9, 1267; cf. Nicol, *C. N.* 43, 43).—5. With aqueous ammoniac sulphide it forms a red powder C<sub>10</sub>H<sub>12</sub>S<sub>2</sub>N<sub>2</sub>O<sub>2</sub>. This dye separates from petroleum in lustrous green crystals (E. Davy, *P. M.* [4], 68, 247; Lerch, *C. C.* 1857, 299).—6. Melted with KClO<sub>3</sub> it reacts violently with production of tri-chloro-acetic acid and decomposition products (Seubert, *B.* 18, 3336).—7. Boiled with zinc dust it is decomposed with formation of chloride and oxychloride of zinc and liberation of hydrogen and CH<sub>4</sub> (Cotton, *Bl.* [2] 42, 622).—8. HgO decomposes chloral hydrate with formation of COCl<sub>2</sub>, carbonic oxide, and CO<sub>2</sub>.—9. KMnO<sub>4</sub> liberates chlorine, CO<sub>2</sub>, and oxygen with formation of CHCl<sub>3</sub> (Cotton, *Bl.* [2], 43, 420).—10. Heated with ammoniac sulphocyanide forms a white crystalline body C<sub>2</sub>H<sub>2</sub>Cl<sub>2</sub>N<sub>2</sub>S, insol. water, sol. alcohol (Nencki a. Schaffer, *J. pr.* 126, 430; Brodsky, *M.* 8, 27).—11. Camphor forms an unstable compound (vol. i. 670).—12. Acetyl chloride forms CCl<sub>3</sub>CHCl(OAc) (Meyer a. Dulk, *B.* 4, 963).—13. With *di-methyl-aniline* and ZnCl<sub>2</sub> it gives CCl<sub>3</sub>CH(OH).C<sub>6</sub>H<sub>4</sub>NMe<sub>2</sub> (Knoeffler a. Boessneck, *B.* 20, 3193).

**Acetyl derivative** CCl<sub>3</sub>CH(OAc). (222° uncor.). S.G. 1.422. From chloral and Ac<sub>2</sub>O. Liquid, insol. water, not attacked by cold KOHAq (Geuther, *A.* 506, 249).

**Ethyl ether** CCl<sub>3</sub>CH(OH)(OEt).

**Chloral alcoholate.** Mol. w. 193.5. [56°] (Jacobsen); [46°] (Lieben, *B.* 3, 909). (115°) (Martius a. Bartholdy, *B.* 3, 443). S.G. 1.329. V.D. (air = 1): 8.49 at 200° (theory: 6.68). The vapour-pressure has been examined by Ramsay a. Young (*C. J.* 49, 686). Formed by the union of chloral with alcohol (Personne, *C. R.* 69, 1363; cf. Roussin, *C. R.* 69, 1144; Thomsen, *B.* 2, 597; Lieben, *B.* 8, 907; Jungfleisch, Lebaigne a. Roucher, *J. Ph.* [4] 9, 208). Its vapour is dissociated by heat. Separated from aqueous solution by CaCl<sub>2</sub>. Decomposed by H<sub>2</sub>SO<sub>4</sub> with liberation of chloral. With PCl<sub>5</sub> it gives tetra-chloro-ether, CCl<sub>3</sub>CHClOEt (Henry, *C. J.* 24, 255, 696; *B.* 4, 101, 435).

**Ethyl-acetyl derivative** CCl<sub>3</sub>(OAc)(OEt). (198° uncor.). S.G. 1.327. From chloral alcoholate and AcCl. Also from tetra-chloro-ether and AgOAc (Busch, *B.* 11, 447).

**Methyl-ethyl ether** CCl<sub>3</sub>(OMe)(OEt). (193.4°). S.G. 1.182. From tetra-chloro-ether and MeOH (Magnanini, *G.* 18, 330). Liquid, smelling like camphor.

**Chloro-ethyl ether** CCl<sub>2</sub>CH(OH)OCH<sub>2</sub>CH<sub>2</sub>Cl. From chloral and glycolic chlorhydrin. Converted by PCl<sub>5</sub> into CCl<sub>2</sub>CHClOCH<sub>2</sub>CH<sub>2</sub>Cl (Henry, *B.* 7, 763).

**Methyl ether** CCl<sub>3</sub>CH(OH)(OMe). **Chloral methyl-alcoholate.** [50°]. (106°) (Jacobsen, *A.* 157, 243); (98°) (Bartholdy a. Martius, *B.* 3, 443). From chloral and methyl alcohol.

**Di-methyl ether** CCl<sub>3</sub>CH(OMe)<sub>2</sub>. (183°). S.G. 1.28. From CCl<sub>3</sub>CHClOCH<sub>2</sub>CH<sub>2</sub> and MeOH. Liquid, smelling of camphor (Magnanini, *G.* 18, 330).

**Di-ethyl ether** CCl<sub>3</sub>CH(OEt)<sub>2</sub>. **Tri-chloro-acetal.** (197°) (B.); (200°) (W. a. V.); (205° cor.) (P. a. P.). S.G. 1.281 (P. a. P.). S. 5. Formed by passing chlorine into dilute (75 p.c.) alcohol; or by treating chloral alcoholate with chlorine at 80° (Byasson, *Bl.* [2] 32, 304; *C. R.* 87, 26). Formed also by treating tetra-chloro-ethyl oxide CCl<sub>2</sub>CHClOCH<sub>2</sub>CH<sub>2</sub>Cl with alcohol in sealed tubes (Wurtz a. Vogt, *C. R.* 74, 777; Paterno a. Pisati, *G.* 2, 333). Liquid, smelling like di-chloro-acetal. Miscible with alcohol and ether. By heating with water or H<sub>2</sub>SO<sub>4</sub> it is resolved into chloral and alcohol. Hot alkali has no action. HNO<sub>3</sub> gives tri-chloro-acetic acid. A solid isomeride is described under CHLORO-ACETIC ALDEHYDE.

**Allyl ether** CCl<sub>3</sub>CH(OH)(OC<sub>2</sub>H<sub>5</sub>). **Chloral allyl-alcoholate.** [21°]. (116°). From chloral and allyl alcohol. Needles (Ogilialoro, *B.* 7, 1462).

**Acetyl derivative** CCl<sub>3</sub>CH(OAc)(OC<sub>2</sub>H<sub>5</sub>). (106°) (Oliveri, *G.* 14, 18).

**Isoamyl ether** CCl<sub>3</sub>CH(OH)(OC<sub>4</sub>H<sub>9</sub>). **Chloral amyl-alcoholate.** [56°]. (146°). S.G. (liquid) 1.234.

**Ethyl ether** CCl<sub>3</sub>CH(OH)(C<sub>2</sub>H<sub>5</sub>). **Chloral ethyl-alcoholate.** Very small needles.

**Ethylene ether** CCl<sub>3</sub>CH(OH).OC<sub>2</sub>H<sub>4</sub>.OC<sub>2</sub>H<sub>4</sub>.OC<sub>2</sub>H<sub>4</sub>. **Chloral glycolate.** From chloral and glycol (Henry, *B.* 7, 762).

**Isomeride of chloral hydrate.** Chloral mixed with glacial HOAc and evaporated quickly is converted into an isomeride of chloral hydrate [80°], although the same solution when evaporated slowly deposits ordinary chloral hydrate [57°] (V. Meyer, *B.* 6, 449; *A.* 171, 74).

**Meta-chloral** (C<sub>2</sub>Cl<sub>3</sub>HO). Formed by leaving chloral to stand with H<sub>2</sub>SO<sub>4</sub>. Chloral that has been freed from all traces of H<sub>2</sub>SO<sub>4</sub> by distillation over BaO remains liquid for years (Byasson, *C. R.* 91, 1071). Amorphous solid, insol. water. HNO<sub>3</sub> oxidises it to tri-chloro-acetic acid. Alkalies form formate and chloroform. At 180° it is converted into ordinary chloral (Kolbe, *A.* 54, 183). Trimethylamine also polymerises chloral.

**Parachloral** (C<sub>2</sub>Cl<sub>3</sub>HO). (240°). Formed, together with tetra-chloro-ethylene, by treating chloral with Al<sub>2</sub>Cl<sub>3</sub> (Combes, *A. Ch.* [5] 12, 268). Liquid; oxidised by HNO<sub>3</sub> to tri-chloro-acetic acid.

**Para-chloralide** (C<sub>2</sub>Cl<sub>3</sub>HO). (182°). S.G. 1.577. An isomeride of chloral acid to be formed by the action of chlorine on methyl alcohol (Cloeze, *A.* 111, 178).

**CHLORALIDE** C<sub>2</sub>H<sub>2</sub>Cl<sub>2</sub>O<sub>2</sub>  
i.e. CCl<sub>3</sub>CH <  $\begin{smallmatrix} \text{CO} \\ \text{O} \end{smallmatrix}$  > CHCl<sub>3</sub>.  
**Tri-chloro-ethylidene tri-chloro-lactate.** [115°].

# CHLORHYDRIC ACID.

8

(273°). V.D. 11.8 at 800° (calc. 1.2). Formed, together with metachloral, by the action of  $H_2SO_4$  on chloral. Also by heating chloral with tri-chloro lactic acid at 150° (Wallach, A. 193, 1; B. 8, 1578).

• *Preparation*.—Chloral hydrate (1 vol.) is heated at 90° with a mixture of conc.  $H_2SO_4$  (1½ vols.) and fuming  $H_2SO_4$  (1¼ vol. of S.G. 1.85) in a flask with inverted condenser until crystallisation begins in the neck of the flask. The contents are shaken till cold, and then poured into water. The insoluble chloralide is washed with water and recrystallised from ether or chloroform (Otto, A. 239, 262; cf. Städelcr, A. 67, 104; Grabowsky, B. 8, 1433; Kekulé, A. 105, 293).

• *Properties*.—Monoclinic prisms (from ether). Insol. water, sol. cold alcohol. Distils without decomposition. Boiling  $KOH$  splits it up into chloroform and formic acid. Alcohol at 130° gives chloral alcoholate and ethyl tri-chloro-lactate [67°]. Zn and HCl in alcoholic solution reduce it to aldehyde and di-chloro-acrylic acid.  $PCl_5$  forms an oil  $C_2HCl_3O_2$ . S.G.  $\frac{2}{3}$  1.7436 (Anschutz a. Haslam, A. 239, 300).

CHLORANIL v. TETRA-CHLORO-QUINONE.

CHLOR-ANILIC ACID v. DI-CHLORO-DI-OXY-QUINONE.

CHLORATES and PERCHLORATES.—Salts of chloric and perchloric acids, v. CHLORINE, OXY-ACIDS OF.

CHLORHYDRIC ACID. HCl (*Hydrochloric acid*, *Hydrazen chloride*, *Muriatic acid* gas). Mol. w. 36.37, [-112.5°] (solidifies at -115.7°) (Olszewski, M. 5, 127). V.D. 18.2. S.H.p. (13°-100°) (equal mass of water=1) .194 (Strecker, W. 17, 85); (27°-214°) .1867 (Regnault, Acad. 26, 1). S.H.v. (equal mass of water=1) .1904; (equal volume of air=1) .975 (Glaissius, *Mechan. Wärmetheorie*, 1, 62 [1876]). S.H.p. (20°) 1.389; (100°) 1.4 (Strecker, W. 19, 85; experimentally determined). C.E. (0°-83°)  $V_1 = V_0 (1 - at + bt^2)$ , values of  $a$  for  $HCl + 6.5H_2O = .000446$ ; for  $HCl + 50H_2O = .0000625$ ; values of  $b$  for  $HCl + 6.5H_2O = .0000043$ ; for  $HCl + 50H_2O = .00000871$ ; for  $HCl + 200H_2O = .0000153$ ; for  $HCl + 200H_2O = .000009768$  (Marignac, A. Suppl. 8, 335).  $S$  at 760 mm. (0°) 503; (4°) 490; (10°) 470; (20°) 440; (24°) 427; (36°) 396; (44°) 377; (48°) 367; (60°) 342.  $S$  at 0° with varying pressure (60 mm.) 374; (100 mm.) 400; (200 mm.) 431; (400 mm.) 450; (400 mm.) 465; (600 mm.) 487; (800 mm.) 507; (1000 mm.) 522; (1800 mm.) 545 (Roscoe a. Dittmar, A. 112, 328; v. also Deicke, P. 119, 156).  $S$ . (alcohol, S.G. .836) 327 (Pierre, A. Ch. [3] 31, 135). Vapour-pressure of liquid HCl (-73°) 1368 mm.; (-51°) 3800 mm.; (-30°) 8056 mm.; (0°) 19912 mm. (Faraday, T. 1845, 155). H.F. [H. Cl] = 2.060; [H. Cl, Aq] = 39.315 (Th. 2, 20). Critical point = 51.95° (Ansell, Pr. 30, 117). S.G. liquid HCl (0°) .908, (7.5°) .873, (33°) .743, (47.8°) .619 (A.). Coefficient of compressibility (liquid HCl) for pressure from 52.8 to 208.19 atmos. at 47° = .00156, at 33° = .00096, at 15.85° = .00062, at 5.7° = .000397 (A.).

• *Occurrence*.—In the gases of volcanoes, and in streams issuing in volcanic districts (Bunsen, P. 88, 197). In the gastric juice of mammals

(Boedeker a. Troschel, B. B. 1854 486). An aqueous solution of HCl has been known for many centuries; the gas was first prepared approximately pure by Priestley in 1774. The acid was thought to be the oxide of an unknown element, *murium*, until Davy proved in 1810 that it was a compound of H and Cl.

• *Formation*.—1. By the action of diffused sunlight on a mixture of equal volumes H and Cl. The mixture is best prepared by electrolysis of conc.  $HClAq$ , using carbon electrodes (Roscoe, C. J. 8, 16). Combination occurs explosively in direct sunlight, or in electric, or magnesium, light, or in the light produced by burning NO in  $CS_2$  vapour. Combination may also be caused by heating to 150°, or by bringing the gases into contact with Pt black, or by absorbing them in charcoal. The gases do not combine in the dark at ordinary temperature. For details regarding the rate of combination by exposure to light v. CHEMICAL CHANGE, vol. i. p. 749. 2. By the action of Cl on  $H_2O$  in sunlight; or Cl on  $H_2S$ , HI, turpentine, and many other organic compounds.—3. By the action of  $H_2SO_4Aq$  or other acid on various metallic chlorides.—4. By the action of superheated steam on  $MgCl_2$ , or on  $CaCl_2$  mixed with sand.

• *Preparation*.—1. By adding to 100 parts pure NaCl, in a flask with an exit tube and safety funnel, about 150 parts pure  $H_2SO_4Aq$ , prepared by diluting the conc. acid with  $\frac{1}{3}$  to  $\frac{1}{2}$  its weight of  $H_2O$  and cooling, and gently warming. The gas is passed through a little conc.  $HClAq$ , and then dried by  $CaCl_2$ ; it is collected over  $Hg$ , or by downward displacement of air. If the materials react in the proportions  $NaCl:H_2SO_4:NaHSO_4$  and HCl are formed at ordinary temperatures; then adding NaCl and strongly heating,  $NaHSO_4$  and NaCl give  $Na_2SO_4$  and HCl. If  $HClAq$  is to be prepared, the gas is led into cold water, the exit tube passing only a little way under the surface: the  $HClAq$  may be purified by redistillation in contact with a little Cu (to remove Cl), after standing with pure  $SnCl_2$  (to remove As), (v. Bettendorff, Z. [2] 5, 492; Zettinow, D. P. J. 205, 247; Hager, Fr. 1872, 306; Oster, Fr. 1872, 465; Houzeau, A. Ch. [4] 7, 484; Reipsch, J. pr. 24, 244; Otto, B. 19, 1903).—2. By dropping conc.  $H_2SO_4Aq$ , through a tube with glass stop-cock, into a flask about one-third filled with commercial  $HClAq$ ; the liquid gets warm and all the HCl except about .32 p.c. is evolved (P. Hoffmann, B. 1, 272). Liquid HCl may be prepared on a small scale by placing a few pieces of  $NH_4Cl$  in the closed end of a V shaped tube, running a little conc.  $H_2SO_4$  by means of a bent funnel tube into the second bend of the tube, closing and thickening the open end, and, after cooling, allowing the acid to flow on to the  $NH_4Cl$ , and cooling the other limb of the tube. After a little the limb containing the reacting bodies is gently warmed when liquid HCl collects in the cooled limb (Davy a. Faraday, T. 1823, 164).

• *Properties*.—HCl is a colourless gas with most irritating, acid odour; it fumes in moist air. The dry gas does not reddén litmus paper. At 10° under pressure of 40 atmospheres HCl condenses to a colourless liquid (Faraday, T. 1845, 155). HCl is largely absorbed by water with production of much heat; [ $HClAq$ ]=

17,314 (*Th.* 2, 19). The solution is strongly acid; the affinity is taken by Ostwald as 100 (*v. Affinity*, vol. i. p. 75). When heated, conc. HClAq gives off HCl and H<sub>2</sub>O; the temperature rises to 110° at mean barometric pressure when a liquid S.G. 1.1 and containing 79.8 p.c. H<sub>2</sub>O and 20.2 p.c. HCl distils over unchanged. This composition corresponds with the formula HCl.8H<sub>2</sub>O; but it is not probable that the liquid is a definite hydrate; the B. P. and composition of the liquid vary with the pressure. The following numbers give the B. P. of HClAq, and the composition of the liquid remaining in the retort, at various pressures (Roscoe a. Dittmar, *A.* 112, 328; v. also Bineau, *A. Ch.* [3] 7, 257):—

Pressure in mm.	B.P.	P.c. HCl in residual liquid.
100	62°	22.8
200	76	22.1
300	84	21.7
490	97	20.9
760	110	20.2
1520	—	18.1
2280	—	18.1

If dry air is passed into conc. HClAq the liquid loses HCl; the residual liquid has a constant composition for a specified temperature. The following numbers give the composition of the HClAq remaining at t° after passage of dry air until HCl ceases to come off (Roscoe a. Dittmar, *A.* 112, 328):—

t°	P.c. HCl.	t°	P.c. HCl.	t°	P.c. HCl.
0°	25.0	35°	23.9	70°	22.6
5	24.9	40	23.8	75	22.3
10	24.7	45	23.6	80	22.0
15	24.6	50	23.4	85	21.7
20	24.4	55	23.2	90	21.4
25	24.3	60	23.0	95	21.1
30	24.1	65	22.8	100	20.7

The following table (Roscoe a. Dittmar) shows that the liquid obtained by passing air into HClAq at a specified temperature has, in many cases, the same composition as the liquid which boils at that temperature under a certain pressure:—

Pres. in mm.	B.P.	P.c. HCl	Temp. with air-stream.	P.c. HCl
100	61°-62	22.8	62°	22.9
210	76-77	22.1	77	22.2
300	84-85	21.7	85	21.7
380	91	21.3	91	21.4
490	97	20.9	98	21.1

The S.G. and composition of HClAq are given in the following table (Ure). Temp. 15°.

1.210	40.2	42.4	132.7	125.0	119.0
1.212	41.7	42.9	134.3	126.6	120.1

Kremers (*P.* 108, 115) gives a table by which

the S.G. of HClAq can be found at a temperature other than 19.5° which temperature is taken as normal. (See table on next page.)

Thus, an acid containing 25.5 p.c. HCl has S.G. = 1.101 at the normal temp. (19.5°), at 40° the S.G. will be  $\frac{1.101}{1.00877} = 1.092$ ; at 100° the S.G.

will be  $\frac{1.101}{1.03867} = 1.06$ . Thomsen, using the num.

bers in Ure's table, gives the S.G. of HClAq at 15° as S.G. =  $\frac{100}{100 - p} \left( \frac{100 - 1.0765 p}{100 - 726 p} \right)^{\frac{1}{3}}$ ,

where  $p$  = p.c. of HCl (*P. Jabelband*, 144).

*Reactions.*—1. Decomposed by heat, at about 1500°, into H and Cl, which combine again on cooling. If a silver tube kept cold by running water is placed inside a porcelain tube in a wind furnace, and HCl is passed through the latter tube, the free Cl combines with the Ag, and H remains (Deville, *C. R.* 60, 317).—2. Moist, but not dry, HCl is decomposed by oxygen in presence of sunlight (Richardson, *C. J.* 51, 801).—3. Electric sparks very slightly decompose HCl.—4. Many metals decompose HCl when heated in it, giving chlorides and H; metallic oxides form H<sub>2</sub>O and Cl; many metallic peroxides also set free Cl.—5. HCl is not combustible.—6. Mixed with air and passed through a hot porcelain tube, or over hot pumice, H<sub>2</sub>O and Cl are formed (comp. CHLORINE; *Formation*, No. 3).—7. By the action of platinum black on a mixture of 1 vol. HCl with  $\frac{1}{2}$  vol. O water is formed (Henry, *T.* 1800, 188).—8. HCl is completely decomposed by sodium amalgam at the ordinary temperature. (This is applied as a lecture experiment for demonstrating the composition of HCl, by Hofmann; *v. Einleitung in die moderne Chemie* (5th ed.), 73).—9. An aqueous solution of HCl exposed to air and sunlight evolves a little Cl.—10. Conc. HClAq evolves only H and Cl on electrolysis; diluted with 9 vols. or more H<sub>2</sub>O, O is also evolved. Riche (*C. R.* 46, 348) says that by electrolysis of HClAq, HClO<sub>2</sub>Aq is formed.—11. Conc. HClAq heated to 200° with amorphous phosphorus produces PH<sub>3</sub> and H<sub>3</sub>PO<sub>4</sub>Aq.—12. An aqueous solution of HCl is decomposed by many metals with formation of chlorides and evolution of H. Let this decomposition be expressed by the equation  $R + 2HClAq = RCl_2Aq + H_2$ ; then considered thermally this is composed of the parts (1) —[H<sup>+</sup>, Cl<sup>-</sup>, Aq], (2) + [R, Cl<sup>-</sup>, Aq]. The value of (1) is about 79,000, but is less the less the quantity of water used; for very conc. solutions it is equal to about 69,000; if then the value of [R, Cl<sup>-</sup>, Aq] is greater than 79,000 we should expect the metal R to decompose dilute HClAq; if [R, Cl<sup>-</sup>, Aq] is greater than 69,000 we should expect R to decompose conc. HClAq. [R, Cl<sup>-</sup>, Aq] is greater than 79,000 when R = K, or other alkali metal, Ag, Cs, Ba, Sr, Mg, Cd; Zn, Mn, Fe, Co, Ni, Sn. [R, Cl<sup>-</sup>, Aq] is less than 79,000 when R = Ti, Pb, Cu, Hg, Pd, Pt, or  $\frac{1}{2}$  Au; these metals do not decompose dilute HClAq. Now [Pb, Cl<sup>-</sup>, Aq] = 75,970, which is < 69,000; Pb decomposes conc. HClAq. The following quantities of heat are produced, per 2 grams of H formed, by the action of certain metals on HClAq; these numbers afford approximate values of the relative intensities of the actions: Mg = 108,800;

# CHLORHYDRIC ACID.

Al = 79,920; Mn = 49,370; Zn = 34,210; Fe = 21,320; Co = 16,190; Ni = 15,070; Sn = 2,510. (Data from Thomsen).—13. When dilute HClAq is added to a dilute solution of a chloride of an alkali, alkaline earth, or magnesium, metal, little or no thermal change occurs; but when a solution of chloride of Au, Pt, Pd, Hg, or Sn is used a considerable quantity of heat is produced: thus,  $[\text{Au}^{\text{Cl}}\text{Aq} \cdot 2\text{HClAq}] = 9,060$ . Several acids containing H, Cl, and Au, Pt, Hg, or Pd, have been prepared as solids; e.g.  $\text{H}_2\text{PtCl}_6 \cdot 6\text{H}_2\text{O}$ ,  $\text{HAuCl}_4 \cdot 4\text{H}_2\text{O}$  &c. There can be little doubt that solutions of AuCl<sub>3</sub> &c. in HClAq contain definite acids; the heats of formation of these acids have been calculated from experimental data by Thomsen (*Th.* 3, 536; v. also the various metals):

R	[R, Cl <sup>+</sup> , 2HClAq]	R	[R, Cl <sup>+</sup> , 2HClAq]	R	[R, Cl <sup>+</sup> , 2HClAq]
Sn	81,000	Sn	156,920	Au	31,800
Hg	61,780	Pd	72,943 (?)		
Pd	47,920	Pt	81,620		
Pt	41,830				

The heats of neutralisation of these acids are the same as that of  $\text{H}_2\text{Cl}_2\text{Aq}$ , viz.  $2 \times 13,740$  (v. also GOLD, MERCURY, PALLADIUM, PLATINUM, TRN).—14. HClAq dissolves many metallic oxides; most peroxides evolve Cl; carbonates of the alkali and alkaline earth metals, and of the heavy metals except Ag, dissolve with evolution of CO<sub>2</sub>; most metallic sulphides are decomposed and H<sub>2</sub>S produced.—15. Heated with bromic or iodic acid, H<sub>2</sub>O and BrCl or ICl are formed.—16. With chloric or hypochlorous acid, and the salts of these acids, Cl is evolved (v. further CHLORIC ACID and CHLORATES, and HYPOCHLOROUS ACID AND HYPOCHLORITES, under CHLORINE, OXY-ACIDS OF, p. 15).—17. When conc. HClAq is mixed with conc. aqueous nitric acid a yellow liquid is formed which dissolves Au, Pt, &c. metals which are insoluble in either HClAq or HNO<sub>3</sub>Aq. This liquid is known as *aqua regia*; its solvent action is due to the presence of Cl and ROCl;  $\text{HNO}_3\text{Aq} + 3\text{HClAq} = 2\text{H}_2\text{O} + \text{NOCl} + \text{Cl}_2$ . By the action of *aqua regia* on metals chlorides are formed; e.g.  $2\text{HNO}_3\text{Aq} + 6\text{HClAq} + 3\text{Cu} = 3\text{CuCl}_2\text{Aq} + 2\text{NO} + 4\text{H}_2\text{O}$ .

According to Gore (*R.M.* 29, 541) liquid HCl does not act on metals, except Al which dissolves with evolution of H; it has also no action on many oxides, sulphides, and carbonates, which are decomposed by HClAq.

**Combinations.**—1. HCl and NH<sub>3</sub> combine when mixed to form NH<sub>4</sub>Cl;  $[\text{NH}_3\text{HCl}] = 41,900$  (*Th.* 2, 75).—2. HCl and PH<sub>3</sub> combine to form PH<sub>4</sub>Cl at 14° under pressure of 20 atmospheres, or at -80 to -85° at the ordinary pressure (Ogier,

*C. R.* 89, 705).—3. HClAq forms acids with the chlorides of Au, Pt, Pd, and Sn (v. *Reactions*, No. 13). According to Ditte (*A. Ch.* [5] 22, 551) some metallic chlorides, e.g. HgCl<sub>2</sub>, dissolve in HClAq to form definite compounds, e.g.  $\text{HgCl}_2 \cdot \text{HCl} \cdot 7\text{H}_2\text{O}$ ;  $\text{SbCl}_3 \cdot 3\text{HCl}$ , &c.—4. With water to form  $\text{HCl} \cdot 2\text{H}_2\text{O}$ , prepared, as very unstable crystals decomposing quickly in air, by passing HCl into HClAq at -22°; crystals separate, and the temperature suddenly rises to -18° (Pierre a. Fugère, *C. R.* 82, 45, v. also Berthelot, *A. Ch.* [5] 14, 368).

Thomsen has measured the heat of dilution of  $\text{HCl} \cdot n\text{H}_2\text{O}$  with  $m\text{H}_2\text{O}$ . Assuming that when  $n = 1$  the H<sub>2</sub>O is in combination with HCl forming the hydrate  $\text{HCl} \cdot \text{H}_2\text{O}$ , then the heat of dilution of  $\text{HCl} \cdot \text{H}_2\text{O}$  is a continuous hyperbolic function of

the quantity of H<sub>2</sub>O added; the equation, heat of dilution of  $\text{HCl} \cdot n\text{H}_2\text{O}$  with  $m\text{H}_2\text{O} = \left(\frac{1}{n} - \frac{1}{n+m}\right)$

11,980, gives values which agree very closely with the observed results, starting with  $n = 2.62$ , and varying  $m$  from 49 to 200; the constant 11,980 is found from the experimental results. The above formula gives the heat of dilution of HCl with 300 H<sub>2</sub>O as 11,940, and the observed value was 17,316; the difference, 5376, represents the quantity of heat produced by the union of HCl with H<sub>2</sub>O to form the hydrate  $\text{HCl} \cdot \text{H}_2\text{O}$ . Thomsen's results do not indicate the formation of any hydrate except  $\text{HCl} \cdot \text{H}_2\text{O}$ ; it is fairly probable that the reactions of HClAq with hydroxides, metals, &c., are the reactions of the compound  $\text{HCl} \cdot \text{H}_2\text{O}$  (? =  $\text{H}_2\text{Cl} \cdot \text{OH}$ ), and not of HCl (*Th.* 3, 11-13; and 68-72) (v. further CHLORIDES). M. M. P. M.

**CHLORIC ACID** & CHLORINE, OXY-ACIDS OF. **CHLORIDES.** Binary compounds of Cl with more positive elements; i.e. with any element except F or O. Cl forms compounds with all elements except F; it combines directly with all except F, O, N, and C: much heat is usually produced during the combination, thus  $[\text{K}^+\text{Cl}^-] = 211,220$ ;  $[\text{Ca}^+\text{Cl}_2^-] = 169,820$ ;  $[\text{Zn}^+\text{Cl}_2^-] = 97,210$ ;  $[\text{Fe}^+\text{Cl}_2^-] = 192,080$ ;  $[\text{Cu}^+\text{Cl}_2^-] = 51,630$ ;  $[\text{Au}^+\text{Cl}_2^-] = 22,820$ ;  $[\text{H}^+\text{Cl}_2^-] = 22,800$ ;  $[\text{I}^+\text{Cl}_2^-] = 5,880$ ;  $[\text{S}^+\text{Cl}_2^-] = 14,260$ ;  $[\text{P}^+\text{Cl}_2^-] = 75,800$ , &c. (Thomsen). Many metallic chlorides are produced by the action of Cl on the oxides e.g.  $\text{ZnCl}_2$ ,  $\text{PbCl}_2$ ,  $\text{MgCl}_2$ ,  $\text{BaCl}_2$ ; lower oxides of metals which

form two oxides—e.g.  $\text{FeO}$ ,  $\text{Sb}_2\text{O}_3$ —are usually partly chlorinated and partly oxidised by  $\text{Cl}_2$ , the higher oxide being usually eventually changed to chloride; all metallic oxides are converted into chlorides when mixed with charcoal and heated in a stream of  $\text{Cl}_2$ , thus  $\text{Cr}_2\text{O}_3 + 3\text{C} + 6\text{Cl}_2 = 3\text{CO} + \text{CrCl}_3$ . Metallic chlorides are also formed by the action of  $\text{Cl}_2$  on many bromides, iodides, fluorides, and sulphides: they are usually obtained by the action of  $\text{HClAq}$  on metals, metallic oxides, hydroxides, or carbonates; in some cases *aqua regia* (v. CHLORHYDRIC ACID; *Reactions*, No. 17) is employed, e.g. to form  $\text{PtCl}_4$ . Non-metals, except  $\text{C}$ ,  $\text{N}$ ,  $\text{O}$ , and  $\text{F}$ , combine directly with  $\text{Cl}_2$ . Nitrogen chloride,  $\text{NCl}_3$ , is extremely explosive, it is formed by the action of  $\text{Cl}_2$  on various ammonium salts in solution;  $\text{CCl}_4$ ,  $\text{C}_2\text{Cl}_6$ ,  $\text{C}_3\text{Cl}_8$ , and  $\text{C}_4\text{Cl}_{10}$ , are formed indirectly from various carbon compounds;  $\text{Cl}_2\text{O}$  is formed by the action of  $\text{Cl}_2$  on  $\text{HgO}$ ,  $\text{ClO}_2$  by the action of  $\text{H}_2\text{SO}_4\text{Aq}$  on  $\text{KClO}_3$ ; no compound of  $\text{Cl}$  with  $\text{F}$  is known. Most non-metallic chlorides are gaseous; they are decomposed by  $\text{H}_2\text{O}$  forming acids and  $\text{HCl}$ , e.g.

Most of the metallic chlorides are gasifiable without decomposition; some yield lower chlorides on heating, e.g.  $\text{CuCl}_2$  gives  $\text{Cu}_2\text{Cl}_2$  and  $\text{Cl}_2$ ; a few are completely decomposed into  $\text{Cl}$  and metals, e.g.  $\text{PdCl}_2$ . A few chlorides are insoluble or nearly insoluble in water—the chief are  $\text{AgCl}$ ,  $\text{Hg}_2\text{Cl}_2$ ,  $\text{Cu}_2\text{Cl}_2$ ,  $\text{PtCl}_2$ ,  $\text{AuCl}_3$ —the others are soluble in water. Many metallic chlorides are decomposed by water, forming oxychlorides and  $\text{HClAq}$ , e.g.  $\text{BiCl}_3$ ,  $\text{SbCl}_3$ ; on evaporating  $\text{AlCl}_3\text{Aq}$ ,  $\text{ZnCl}_2\text{Aq}$ ,  $\text{MgCl}_2\text{Aq}$ , and a few other solutions of chlorides, decomposition into oxide and  $\text{HCl}$  or into oxychloride, occurs. Heated in superheated steam chlorides of alkali metals,  $\text{Ba}$  and  $\text{Hg}$ , are undecomposed; the others form oxides and  $\text{HCl}$  (Kunheim, *J.* 1861. 149). Most metallic chlorides are unchanged when heated in dry air; some, however, form oxychlorides, e.g.  $\text{FeCl}_3$ ,  $\text{CuCl}_2$ ,  $\text{BiCl}_3$ ; very many are decomposed by heating in moist air. The chlorides of the alkali, alkaline earth, and earth, metals are not reduced by heating in  $\text{H}_2$ ; the other metallic chlorides are reduced; some chlorides not reduced by  $\text{H}_2$ , e.g.  $\text{AlCl}_3$ ,  $\text{MgCl}_2$ , are dechlorinated by heating with  $\text{K}$  or  $\text{Na}$ . Very many chlorides are reduced to metal by  $\text{CO}$ . Some chlorides of heavy metals, e.g.  $\text{AgCl}$ , are partially decomposed by digestion with aqueous solutions of bromides of alkali, alkaline earth, or magnesium, metals (v. Potilitz, *B.* 18. 1522; also Thorpe & Rodger, *C. J. Proc.* 1887–88, 20). Many metallic chlorides are partially decomposed when heated with an equivalent quantity of  $\text{Br}$  to  $270^\circ\text{--}300^\circ$  (v. Potilitz, *B.* 14. 104; 15. 918; 16. 3051. For action of  $\text{Br}$  on  $\text{AgCl}$  in presence of  $\text{H}_2\text{O}$ , v. Hampidge, *B.* 17. 1838). Metallic chlorides are decomposed, with evolution of  $\text{Cl}_2$ , by heating with  $\text{B}_2\text{O}_3$ ,  $\text{SiO}_2$ , or  $\text{P}_2\text{O}_5$ , in presence of steam. Aqueous acids decompose metallic chlorides, forming  $\text{HCl}$ , or in the cases of easily reducible acids—e.g.  $\text{HNO}_3$ —evolving  $\text{Cl}_2$ ;  $\text{Cl}_2$  is also evolved when conc.  $\text{H}_2\text{SO}_4$  is used in presence of peroxide of  $\text{Pb}$ ,  $\text{Mn}$ ,  $\text{Cr}$ , &c. Heated with  $\text{K}_2\text{Cr}_2\text{O}_7$  and conc.  $\text{H}_2\text{SO}_4$ , metallic chlorides form  $\text{CrO}_2\text{Cl}_2$ , which may be easily con-

densed to a red liquid; by the action of  $\text{NH}_3\text{Aq}$  on this liquid ( $\text{NH}_3\text{CrO}_2\text{Cl}$  is formed (this reaction may be applied to detect chlorides in presence of bromides)).

Some metallic chlorides, especially those of  $\text{Hg}$ ,  $\text{Au}$ ,  $\text{Pt}$ ,  $\text{Pd}$ , and  $\text{Sn}$ , combine with  $\text{HCl}$  to form acids (v. CHLORHYDRIC ACID; *Reactions*, No. 13); many form double salts with other metallic chlorides, especially the chlorides of the less positive, with those of the very positive, metals; e.g.  $\text{SnCl}_4 \cdot 2\text{KCl} \cdot \text{H}_2\text{O}$ ,  $\text{HgCl}_2 \cdot 2\text{KCl} \cdot \text{H}_2\text{O}$ ,  $\text{PtCl}_4 \cdot 2\text{NH}_4\text{Cl}$ , &c. Many chlorides of the more negative metals, e.g.  $\text{SbCl}_3$ ,  $\text{BiCl}_3$ ,  $\text{SnCl}_4$ , &c., combine with oxides of the same metals to form oxychlorides: some metallic chlorides, e.g.  $\text{HgCl}_2$ , combine with sulphides of the same metals to form sulphochlorides. Compounds are also known of chlorides of some of the more negative metals with non-metallic chlorides, e.g.  $\text{SnCl}_4 \cdot \text{PCl}_5$ ,  $\text{SnCl}_4 \cdot 2\text{SCl}_2$ , &c. Many metallic chlorides, e.g.  $\text{CaCl}_2$ ,  $\text{AlCl}_3$ ,  $\text{AgCl}$ ,  $\text{CoCl}_2$ ,  $\text{CrCl}_3$ ,  $\text{HgCl}_2$ ,  $\text{PtCl}_4$ , combine with  $\text{NH}_3$  to form stable compounds (v. AMMONIUM COMPOUNDS; and, in more detail, the various metals, especially CHROMIUM, COBALT, COPPER, MERCURY, PLATINUM). ●

Thomsen has considered the isomorphism of the hydrated metallic chlorides (v. *Th.* 2. 430). Many chlorides produced by the action of  $\text{HClAq}$  on metals or metallic oxides contain water of crystallisation; they may be divided into the four groups: (1)  $\text{RCl}_2 \cdot 2\text{H}_2\text{O}$ ; (2)  $\text{RCl}_2 \cdot 4\text{H}_2\text{O}$ ; (3)  $\text{RCl}_2 \cdot 6\text{H}_2\text{O}$ ; (4)  $\text{RCl}_2 \cdot 8\text{H}_2\text{O}$ ; when  $\text{R}$  = an atom of a divalent, or two atoms of a monovalent, metal. The members of group (1), where  $\text{R}$  =  $\text{Ba}$ ,  $\text{Cu}$ , or  $\text{MnHg}$ , crystallising in the trimetric system, are isomorphous with many anhydrous sulphates, formates, perchlorates, periodates, and permanganates, e.g.  $\text{BaSO}_4$ ,  $\text{PbSO}_4$ ,  $\text{Ba}(\text{CH}_3\text{O})_2$ ,  $\text{KClO}_4$ ,  $\text{KIO}_4$ ,  $\text{K}_2\text{Mn}_2\text{O}_8$ , &c. The members of group (2), where  $\text{R}$  =  $\text{Na}$ ,  $\text{Mn}$ ,  $\text{Di}$ ,  $\text{Fe}$ , crystallising in the monoclinic system, are isomorphous with sulphates and formates containing  $2\text{H}_2\text{O}$ , e.g. with  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ,  $\text{Zn}(\text{CHO}_2)_2 \cdot 2\text{H}_2\text{O}$ . Group (3) comprises (a) monoclinic chlorides where  $\text{R}$  =  $\text{Mg}$ ,  $\text{Ni}$ ,  $\text{Co}$ , or  $\text{Mn}$ , these are most probably isomorphous with  $\text{Cu}(\text{CHO}_2)_2 \cdot 4\text{H}_2\text{O}$ ,  $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$ , and  $\text{Ba}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ ; and (b) hexagonal chlorides where  $\text{R}$  =  $\text{Ca}$  or  $\text{Sr}$ , and also the class  $\text{R}^2\text{R}'\text{Cl}_2 \cdot 6\text{H}_2\text{O}$  which includes salts derived from  $\text{H}_2\text{PtCl}_6$  and  $\text{H}_2\text{SnCl}_6$ , these are isomorphous with many sulphites and double nitrates with  $4\text{H}_2\text{O}$ , e.g.  $\text{Sr}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ ,  $\text{Ce}_2\text{Mg}(\text{NO}_3)_4 \cdot 4\text{H}_2\text{O}$ ,  $\text{LaNi}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ , &c. Group (4) contains only one chloride,  $\text{CoCl}_2 \cdot 8\text{H}_2\text{O}$ ; it is isomorphous with the chlorates of  $\text{Co}$ ,  $\text{Cu}$ , and  $\text{Ni}$ , and with the hypophosphites of  $\text{Co}$ ,  $\text{Fe}$ ,  $\text{Mg}$ ,  $\text{Ni}$ , and  $\text{Zn}$ , containing  $6\text{H}_2\text{O}$ . Each group of chlorides is isomorphous with other salts containing  $2\text{H}_2\text{O}$  less than the chlorides. Thomsen concludes that the  $2\text{H}_2\text{O}$  may be best regarded as forming part of the acid radicle; he would represent the four groups of chlorides as

(1)  $\text{R}(\text{HClO}_2)$ ; (2)  $\text{R}(\text{HClO}_2) \cdot 2\text{H}_2\text{O}$ ;  
(3)  $\text{R}(\text{HClO}_2) \cdot 4\text{H}_2\text{O}$ ; (4)  $\text{R}(\text{HClO}_2) \cdot 6\text{H}_2\text{O}$ : all being derived from the acid  $\text{H}_2\text{ClO}_2\text{H}$ , which possibly exists in an aqueous solution of  $\text{HCl}$  (v. CHLORHYDRIC ACID; *Combinations*, No. 4). Armstrong (*B. A.* 1885 Meeting; Presidential address to Section A.) suggests that the name chlorhydric acid should be given to the acid present in an aqueous solution of  $\text{HCl}$ , and that

HCl itself should always be called hydrogen chloride. M. M. P. M.

**CHLORIDE OF LIME**—*Bleaching powder, v. HYPOCHLORITES* under **CHLORINE, OXY-ACIDS** or (p. 17).

**CHLORIDES, ORGANIC** *v.* **CHLORO-COMPOUNDS**.

**CHLORINE**. Cl. (*Dephlogisticated muriatic acid gas*.) At. w. 35.37. Mol. w. 70.74. ( $\gamma$ -33.4° at 760 mm. (Regnault). Solidifies at about -102° (Olszewski, *M.* 5, 127). S.G. (liquid) 1.33 (Faraday, *T.* 1823, 160 a. 198). V.D. 35.8 (*v. Properties*, p. 11). S.H.p. (18°-202°) (equal mass of H<sub>2</sub>O=1) 1.241 (Regnault, *Acad.* 26, 1). S.H.v. (equal mass of H<sub>2</sub>O=1) .0928; (equal volume of air=1) 1.35 (Clausius, *Mechan.*

*Wärmethorie*, [1876] 1, 62). S.H.p. (20°-34°) S.H.v.

1.323 (Streeker, *W.* 13, 20; experimentally determined). Vol. absorbed by 1 vol. H<sub>2</sub>O at 760 mm. = 3.0361 - .046196t + .000110t<sup>2</sup> (Schönfeld, *A.* 95, 1).  $\frac{A-1}{d} \times \text{At. w.} = 10.6$  (Gladstone,

*T.* 1870, 9). Emission-spectrum; principal lines are a group of 4 about 6670, followed by 9 others and then by one with wave-length 4130 (Salet, *A. Ch.* [4] 28, 24). Absorption-spectrum marked by many irregularly distributed lines; the violet is nearly wholly absorbed (Morren, *C. R.* 68, 376; Gernez, *C. R.* 74, 660).

Chlorine was discovered by Scheele in 1774 and supposed by him to be hydrochloric acid deprived of phlogiston. Berthollet regarded it as oxygenated hydrochloric acid; chlorine and hydrochloric acid were long supposed to be oxygen compounds of an unknown element. In 1809 Gay-Lussac and Thénard, showed that chlorine behaves like an element; in 1810 Davy established the elementary character of the body and gave it the name chlorine (*χλωρός*=yellow-green) (Scheele, *Opusc.* 1, 247; Berthollet, *Acad.* 1785, 286; Davy, *T.* 1810; Gay-Lussac a. Thénard, *G. A.* 35, 8; *A. Ch.* 91, 96).

**Occurrence**.—Never free; but in combination with very many metals in various rocks; in sea-water as NaCl; chlorides occur in plant-ash and in many parts of animals.

**Formation**.—1. By the action of conc. HClAq on MnO<sub>2</sub> (MnO<sub>2</sub> + 4HClAq = MnCl<sub>2</sub>Aq + 2H<sub>2</sub>O + Cl<sub>2</sub>); or better by using 1 part MnO<sub>2</sub>, 2 parts HClAq (S.G. 1.14), and 1 part conc. H<sub>2</sub>SO<sub>4</sub> diluted with its own weight of water (MnO<sub>2</sub> + 2HClAq + H<sub>2</sub>SO<sub>4</sub> = MnSO<sub>4</sub>Aq + 2H<sub>2</sub>O + Cl<sub>2</sub>).—2. By the action of conc. H<sub>2</sub>SO<sub>4</sub> on a mixture of NaCl and NaNO<sub>2</sub>; the NO<sub>2</sub> produced is absorbed by conc. H<sub>2</sub>SO<sub>4</sub> (2NaCl + 2NaNO<sub>2</sub> + 2H<sub>2</sub>SO<sub>4</sub> = 2Na<sub>2</sub>SO<sub>4</sub> + 2NO + 2H<sub>2</sub>O + Cl<sub>2</sub>) (Dunlop, *D. P. J.* 151, 48).—3. By the action of a porous substance, *e.g.* clay, on HCl mixed with air. Deacon (*C. N.* 22, 157) soaks clay-bricks in saturated CuSO<sub>4</sub>Aq, and heats them to 370°-400° in a stream of 5 vols. air and 2 vols. HCl; Cl is evolved (*v.* Deacon, *C. A.* [2] 10, 275). Probably CuCl<sub>2</sub> is formed and decomposed to Cu<sub>2</sub>Cl<sub>2</sub> and Cl, and the Cu<sub>2</sub>Cl<sub>2</sub> is again decomposed by the air to CuO and Cl, the CuO being changed to CuCl<sub>2</sub> by the HCl (Hengsen, *B.* 9, 1674).

**Preparation**.—1. 100 grams pyrolusite

(MnO<sub>2</sub>) free from carbonates are well mixed with 130 grams NaCl, and placed in a capacious flask; a cold mixture of 125 c.c. conc. H<sub>2</sub>SO<sub>4</sub> (S.G. 1.85) with 105 c.c. water is added. Cl is evolved; after a time the flask is warmed in a water bath; about 80 grams of Cl are obtainable from the above quantities. The Cl carries over with it a little HCl, and sometimes MnCl<sub>2</sub>; it is passed through CuSO<sub>4</sub>Aq (CuCl<sub>2</sub>Aq and H<sub>2</sub>SO<sub>4</sub> are formed) and then through water. If dry Cl is required the gas must be passed through several tubes containing CaCl<sub>2</sub>, and through one or two long tubes filled with pumice soaked in boiled H<sub>2</sub>SO<sub>4</sub>. The gas may be collected by downward displacement, or over warm water or saturated NaClAq.—2. Crystals of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> are acted on by conc. HClAq in a capacious flask, the acid being added little by little (14HClAq + K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> = 2CrCl<sub>3</sub>Aq + 2KClAq + 7H<sub>2</sub>O + 3Cl<sub>2</sub>).—3. Chloride of lime is decomposed by HClAq (Ca(ClO)<sub>2</sub> + 4HClAq = CaCl<sub>2</sub>Aq + 2H<sub>2</sub>O + 2Cl<sub>2</sub>). Kammerer (*B.* 9, 1548) describes a lecture-apparatus for the convenient preparation of Cl, based on this reaction. Dry chloride of lime, intimately mixed with burnt gypsum, is slightly moistened so that it can be rolled with difficulty into balls between the fingers; the mixture is powdered in an iron mortar and then beaten into an iron frame 10-12 mm. in height; the frame is then covered with oilcloth and very strongly compressed; the compressed plate is cut into cubes, which are preserved in a stoppered bottle. When these cubes are used in a Kipp's apparatus with HClAq of S.G. 1.124 (free from H<sub>2</sub>SO<sub>4</sub>) diluted with its own volume of water, a steady stream of chlorine is obtained (Winkler, *B.* 20, 184).

**Liquid Chlorine** is prepared (Faraday, *T.* 1823, 160 & 198) by placing crystals of Cl<sub>2</sub>5H<sub>2</sub>O, thoroughly pressed between folds of paper at 0°, in the closed end of a  $\Lambda$  tube, closing the other end, placing the Cl<sub>2</sub>5H<sub>2</sub>O in water at 35°, and the other limb of the tube in a mixture of snow and salt (*v.* also Biewend, *J. pr.* 15, 440). Mohr (*A.* 22, 162) mixes a mixture of dry KHSO<sub>4</sub>, NaCl, and MnO<sub>2</sub> in the longer limb of a  $\Lambda$  tube, and above this a layer of CaCl<sub>2</sub>; the shorter limb is closed, and placed in a mixture of snow and salt; the mixture in the longer limb is then heated, and, when liquid Cl has collected in the other limb, is again cooled to prevent re-absorption of the Cl. The operation must be conducted in the dark, else HCl and NO are produced, and the tube is liable to be broken. Liquid Cl is solidified by surrounding with liquid C<sub>2</sub>H<sub>5</sub> and lowering the pressure (Olszewski, *M.* 5, 127).

**Properties**.—A greenish-yellow gas, becoming darker in colour when heated; very irritating odour; liquefied at 15° under pressure of 4 atmospheres (Faraday, *T.* 1823, 160 & 198); at 0° under pressure of 6 atmospheres, and at 12.5° under 8½ atmos. (Niemann). Liquid Cl is dark yellow; immiscible with water; S.G. 1.33; B.P. -33.6° at 760 mm.; non-conductor of electricity (Regnault). Very poisonous; even when mixed with much air it attacks the mucous membranes and causes irritation and even blood-spitting. When working with Cl, the nose and mouth should be protected by a charcoal respirator, or

by a cloth dipped in alcohol. Absorbed by porous substances, e.g. charcoal, with production of heat (v. Melsens, *C. R.* 76, 92); not combustible in  $O_2$  but burns in  $H$  producing  $HCl$ . Dissolves in water with production of heat,  $[Cl^2, Aq] = 2600$  (*Th.* 2, 400). Schönfield gives these data (*A.* 93, 26; 95, 8):—

1 vol. water absorbs  $x$  vols.  $Cl^2$  at 760 mm.

$t^\circ$	$x$	$t^\circ$	$x$	$t^\circ$	$x$
10	2.5852	21	2.7148	31	1.7104
11	2.5443	22	2.0734	32	1.6712

Solubility is greatest at  $10^\circ$ ; chlorine-water is therefore best prepared by leading  $Cl$  into  $H_2O$  kept at about  $10^\circ$  and repeatedly shaking. Solution of  $Cl$  in  $H_2O$  has smell of gaseous  $Cl$ ; it freezes at  $0^\circ$ , giving  $Cl$  hydrate and ice (v. *Combinations*, No. 3); loses all  $Cl$  on boiling (on loss of  $Cl$  from  $Cl$ -water at  $100^\circ$  in closed vessels, v. *Pickering*, *C. J.* 37, 139); decomposes quickly in direct sunlight into  $HCl$  and  $O$ . The presence of  $HCl$  in  $Cl$ -water is detected by shaking with  $Hg$  until the smell of  $Cl$  is removed, filtering, and testing filtrate with blue litmus and with  $AgNO_3$  *Aq.*

The atomic weight of  $Cl$  has been determined (1) by analyses, and determinations of V.D., of many gaseous compounds, e.g.  $CH_3Cl$ ,  $CH_2Cl_2$ ,  $Cl_2Zn$ ,  $Cl_2Bi$ ,  $Cl_2C$ ,  $Cl_2Ta$ ,  $Cl_2W$ , &c.; (2) by comparison of chlorides, &c., with isomorphous bromides, iodides, &c.; (3) by conversion of  $Ag$  into  $AgCl$  by *Berzelius* (*P.* 8, 17); by conversion of  $NaClO_2$  and  $KClO_2$  into  $NaCl$  and  $KCl$  by *Penny* (*J.* 129, 25); by conversion of  $KClO_2$  to  $HCl$  and  $KClO_2$  to  $HCl$  by *Margnac* (*A.* 44, 18); by conversion of  $KClO_2$  to  $KCl$  by heat, and by decomposition of  $KClO_2$  by  $HCl$ , by *Stas* (*Rech.* 118); by heating  $Ag$  in  $Cl$ , by *ppg.*  $Ag$  solution by gaseous  $HCl$ , also by  $HCl$  *Aq.*, also by  $NH_4Cl$  *Aq.*, by *Stas* (*Rech.* 38, 42, 44); by reducing  $AgClO_2$  by  $SO_2$  *Aq.* by *Stas* (*Nouv. R.* 208).

The atom of  $Cl$  is monovalent in gaseous molecules.  $Cl$  acts as a very negative, acid-forming, element; it appears to be positive to  $O$ , and probably to  $F$ . Combines with all elements except  $F$ , directly with all except  $N$ ,  $O$ ,  $C$ , and  $P$ , with many elements combination occurs at ordinary temperatures with production of much heat (v. *Chlorine*). Replacement of  $H$  in carbon compounds by  $Cl$  is usually accompanied by production, or increase, of acidic character, e.g. relative affinity of  $CH_3$ ,  $CH_2Cl$ ,  $CHCl_2$ ,  $CCl_3$  is greater than that of  $CH_3$ ,  $CO_2H$  (v. *Affinity*, vol. i. p. 89). If rate of formation, in solution, of metallic chlorides is greater than those of corresponding bromides or iodides, bromides are wholly or partially decomposed, iodides are easily decomposed by  $Cl$ . At least two oxides of  $Cl$  are known as gases; one oxy-acid,  $HClO_2$ , has been obtained in separate and definite form (v. *Chlorides*; *HALOGEN ELEMENTS*; and *HALOGEN ELEMENTS, BINARY COMPOUNDS OF*).

The S.G. of  $Cl$  gas at  $200^\circ$  was found by *Ludwig* to be 2.45 (air = 1) (*B.* 1, 432). Many determinations have been made by *V. Meyer* and his pupils, using  $Cl$  prepared before and also during the experiments; the general result is that the S.G. of  $Cl$  is very slightly, if at all, less at high temperatures,  $1000^\circ$ – $1400^\circ$ , than at a red heat (v. *Langer* a. *Meyer*, *B.* 15, 2769; also *Crafts*, *A.* 16, 457); but that the S.G. of  $Cl$  formed in the apparatus by heating  $PtCl_2$  at  $1200^\circ$ , is 2.05 (air = 1) in place of 2.45 calculated for  $Cl_2$  (v. *V. Meyer*, *B.* 13, 721). The determinations of *Jahn* (*B.* 15, 1242) show that  $Cl$  does not attain the S.G. calculated for  $Cl_2$  until it is heated to about  $240^\circ$  above its B.P.; the differences between the observed and calculated numbers are however very small, much less than the differences in the case of  $Br$  (q. v.) (v. *HALOGEN ELEMENTS*).

**Reactions.**—1.  $Cl$  dissolves in water with production of heat ( $[Cl^2, Aq] = 2,600$  (*Th.* 2, 400)); the solution decomposes, rapidly in direct sunlight, with formation of  $HCl$  and  $O$ ; according to *Popper* (*A.* 227, 161)  $HClO_2$  is also formed. Chlorine water therefore acts as an oxidiser, e.g. in bleaching (*Poussaint*, *A.* 137, 114). The thermal value is,  $2[H, Cl, Aq] - [H_2, O] = 10,270$  (*Thomsen*).—2.  $Cl$  decomposes steam rapidly when a mixture of the two is passed through a red-hot tube.—3. Aqueous solutions of *potash* (or *soda*) absorb  $Cl$ , yielding  $KCl$  and  $KClO$  in cold, and  $KCl$  and  $KClO_2$  in hot, solution:  $Ca(OH)_2$  absorbs  $Cl$  forming  $CaOCl_2$ .—4. Aqueous ammonia yields  $NH_4Cl$  and  $N$ ;  $Cl$  is in excess chloride of  $N$  is formed.—5. The more basic metallic oxides are decomposed by  $Cl$ , when dissolved or suspended in water, with formation of metallic chloride and peroxide, or metallic chloride and an oxygen compound of  $Cl$  (v. *Chlorine*, oxides of). Many metallic oxides when heated in  $Cl$  give chlorides and  $O$ ; in some cases, e.g.  $Al_2O_3$ ,  $B_2O_3$ ,  $O$  is removed only when  $Cl$  is passed over a hot mixture of the oxide with carbon.—6. All compounds of hydrogen, except  $H_2F$ , are decomposed by  $Cl$  with formation of  $HCl$ ; many at ordinary temperatures; e.g.  $H_2P$ ,  $H_2As$ ,  $H_2S$ ,  $HI$ .—7. All metallic bromides, iodides, and sulphides are decomposed either at ordinary or higher temperatures.—8. Carbon compounds containing hydrogen are usually easily decomposed by  $Cl$ , with formation of  $HCl$ , and frequently with separation of  $C$ ; turpentine e.g. burns in  $Cl$  with a deposit of soot. Some vegetable colours are bleached by  $Cl$  by direct removal of  $H$ ; in most cases, however, the action requires the presence of  $H_2O$  and is due to the  $O$  evolved in contact with the colouring matter. (For the reactions of  $Cl$  with  $Ag$  salts v. *Krutwig*, *B.* 14, 304.)—9. An aqueous solution of sodium thiosulphate is decomposed by  $Cl$ ; the chief reactions are (1)  $Na_2S_2O_3 \cdot Aq + 5H_2O + 8Cl = Na_2SO_4 \cdot Aq + 8HClAq + H_2SO_4 \cdot Aq$ ; (2)  $Na_2S_2O_3 \cdot Aq + 2Cl + H_2O = Na_2SO_4 \cdot Aq + 2HClAq + S$ ; (3)  $2Na_2S_2O_3 \cdot Aq + Cl = Na_2S_2O_4 \cdot Aq + 2NaClAq$ . On dilution  $H_2S$  is evolved; probably,  $2Na_2S_2O_3 \cdot Aq = Na_2S_2O_4 \cdot Aq + Na_2SAq$ ; and then  $Na_2SAq + 2HClAq$  (formed as in (1))  $= 2NaClAq + H_2S$  (v. *Lunge*, *B.* 12, 404).—10. Many salts are decomposed by  $Cl$  with formation

of aqueous solutions of  $\text{HClO}$ : e.g.

**Combinations.**—1. Directly with all elements except O, N, C, and F; indirectly also with O, N, and C. In most cases much heat is produced (v. CHLORIDES). Dry Cl has no action on dry Na (Wanklyn, *C. N.* 20, 271); K, Na, and Sb, do not combine with liquid Cl at  $-80^\circ$ ; P and As on the other hand combine readily (Donny, *A. Mareska*, *A.* 56, 160). The combination of Cl and H takes place slowly in the dark, but very rapidly and explosively in direct sunlight, in electric light, in Mg light, or in the light produced by burning  $\text{CS}_2$  in  $\text{NO}$ ;  $[\text{H}, \text{Cl}] = 22,000$  (Thomsen). For more details regarding the combination of Cl and H v. CHLORHYDRIC ACID, p. 5; also CHEMICAL CHANGE, vol. i. p. 749.—2. Cl condensed in charcoal combines, without the aid of heat or light, with sulphur dioxide to form  $\text{SO}_2\text{Cl}_2$  (Melsens, *C. R.* 76, 92).—3. Cl combines with water: when a saturated aqueous solution is cooled to  $0^\circ$ , or when Cl is led into  $\text{H}_2\text{O}$  kept nearly at  $0^\circ$ , crystals of  $\text{Cl}_5\text{H}_9\text{O}$  separate out (Faraday, *Q. J. S.* 15, 71). This hydrate is best prepared by passing Cl into a little water in a flask surrounded by ice, till the water is changed to a thick yellowish magma; and then pressing strongly between thick layers of paper kept at  $0^\circ$ .  $\text{Cl}_5\text{H}_9\text{O}$  at  $-50^\circ$  forms white tetrametric octahedra, which may be sublimed (? with partial decomposition) in a closed vessel filled with Cl, the upper part being kept below  $0^\circ$ .  $\text{Cl}_5\text{H}_9\text{O}$  decomposes at ordinary temperatures and pressures with evolution of Cl and formation of Cl water; in a closed tube it separates into Cl and  $\text{H}_2\text{O}$  at about  $35^\circ$ ; on cooling to  $15^\circ$  or so the  $\text{Cl}_5\text{H}_9\text{O}$  is re-formed (v. p. 10, *Liquid chlorine*) (compare Wöhler, *A.* 85, 374).

**Detection and Estimation.**—Chlorine decomposes  $\text{KI}$  giving  $\text{KClAq}$  and  $\text{IAq}$ , the I is detected by the blue colour it produces with starch paste. Soluble chlorides ppt. Ag as white  $\text{AgCl}$  from  $\text{AgNO}_3\text{Aq}$ . Solid chlorides when heated with  $\text{K}_2\text{Cr}_2\text{O}_7$  and conc.  $\text{H}_2\text{SO}_4$  produce fuscous  $\text{Cr}_2\text{O}_3$ , which is easily condensed to a reddish-brown liquid; bromides and iodides under similar conditions give Br and I respectively.

Chlorine in dilute aqueous solutions may be estimated volumetrically (1) by determining the mass of I (by means of standardised  $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ ) set free from  $\text{KIAq}$  by the Cl, or (2) by gently warming in a closed vessel with excess of  $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ —whereby part of the  $\text{Na}_2\text{S}_2\text{O}_3$  is changed to  $\text{NaHSO}_3$ —decomposing the remaining  $\text{Na}_2\text{S}_2\text{O}_3$  by boiling with  $\text{HClAq}$ , and estimating the sulphate produced by the usual methods. Chlorides, in solution, may be estimated (1) by ppg. as  $\text{AgCl}$ , washing, drying, slightly fusing, and weighing; or (2) volumetrically by means of standardised  $\text{AgNO}_3\text{Aq}$ , in presence of a very little  $\text{K}_2\text{Cr}_2\text{O}_7$ ; the  $\text{AgNO}_3\text{Aq}$  is added until the whole of the chlorine is pptd. as  $\text{AgCl}$ , the completion of the reaction being determined by noticing the production of red

$\text{Ag}_2\text{CrO}_4$ ; the chloride ought to be present in the liquid as alkali or alkali-earth chloride; the liquid must be neutral to litmus. The reaction of chlorides with  $\text{K}_2\text{Cr}_2\text{O}_7$  and conc.  $\text{H}_2\text{SO}_4$  may also be applied to the estimation of Cl in presence of I and Br (v. Dechan, *C. R.* [2] 49, 382).

**CHLORINE BROMIDE** OF: better called Bromine chloride; v. BROMINE.

**CHLORINE CYANIDES** OF: better called Cyanogen chlorides; v. CYANOGEN.

**CHLORINE HYDRATE** OF:  $\text{Cl}_5\text{H}_9\text{O}$ . Obtained by passing Cl into  $\text{H}_2\text{O}$  at  $0^\circ$ ; v. CHLORINE; *Combinations*, No. 3.

**CHLORINE IODIDES** OF:  $\text{ICl}$  and  $\text{ICl}_2$ ; better called Iodine chlorides; v. IODINE.

**CHLORINE OXIDES** OF: Chlorine and oxygen do not combine directly. Two oxides of Cl,  $\text{Cl}_2\text{O}$  and  $\text{ClO}_2$ , certainly exist; a third is usually described as  $\text{Cl}_2\text{O}_3$ , but it is probably a mixture of  $\text{ClO}_2$  and  $\text{Cl}$  (v. CHLORINE TRIOXIDE). They are all unstable bodies, easily decomposing into their elements.  $\text{Cl}_2\text{O}$  is the anhydride of  $\text{HClO}$ , but this acid is known only in dilute aqueous solutions. The anhydride  $\text{Cl}_2\text{O}$  cannot be obtained from solutions of the acid;  $\text{Cl}_2\text{O}$  is prepared by the action of Cl on dry  $\text{H}_2\text{O}$ . The supposed  $\text{Cl}_2\text{O}_3$  is said to be obtained by reducing  $\text{HClO}_4\text{Aq}$ , generally by  $\text{As}_2\text{O}_3$ .  $\text{ClO}_2$  is not an anhydride of a definite acid; it is obtained by the action of  $\text{H}_2\text{SO}_4\text{Aq}$  on  $\text{KClO}_3$ , on addition of  $\text{H}_2\text{O}$ , or  $\text{KOH}$ , it forms  $\text{HClO}_4\text{Aq}$  and  $\text{HClO}_3\text{Aq}$ , or  $\text{KClO}_4\text{Aq}$  and  $\text{KClO}_3\text{Aq}$ . The hypothetical anhydrides of  $\text{HClO}_3$  and  $\text{HClO}_4$ , viz.  $\text{Cl}_2\text{O}_3$  and  $\text{Cl}_2\text{O}_4$ , are unknown. The heat of formation of  $\text{Cl}_2\text{O}$  is negative;  $[\text{Cl}_2\text{O}] = -17,900$  (Thomsen). The heat of formation of the only known oxide of I, viz.  $\text{I}_2\text{O}_5$ , has a large positive value  $[\text{I}_2\text{O}_5] = 45,000$  (Thomsen).

Berthelot discovered  $\text{KClO}_4$  in 1786; it was long known as oxidised potassium chloride. Other compounds containing Cl and O were prepared and examined by Chevenix (1802), Stadion and Davy (1815), and by Balard (1834). Millon in 1843 added much to the knowledge of the oxy-compounds of Cl. In more recent times Carius, Brandau, and Pebal have examined these compounds. The body called by Davy *euchlorine*, obtained by the action of  $\text{HClAq}$  on  $\text{KClO}_3$ , and supposed by him to be an oxide of Cl, has been proved to be a mixture of  $\text{ClO}_2$  with Cl. Millon's compounds  $\text{Cl}_2\text{O}_3$  and  $\text{Cl}_2\text{O}_4$ , have also been shown to be mixtures (H. Davy, *T.* 1815, 214; Gay-Lussac, *A. Ch.* 8, 408; Soubeiran, *A. Ch.* 43, 113; J. Davy, *N. Ed. P. J.* 17, 49; Millon, *A. Ch.* [3] 7, 298; Pebal, *A.* 177, 1).

**I. CHLORINE MONOXIDE.**  $\text{Cl}_2\text{O}$ : (*Hypochlorous anhydride*). Mol. w. 86.7. ( $6^\circ$  at 7.8 mm.) (Garzaroli, *Churnlagh*, *A.* 230, 276). *D.* 43.5 at  $10^\circ$ .  $[\text{Cl}_2\text{O}] = -17,930$  (*T.* 2, 390). S.G. 3.977 (air = 1). Absorption-spectrum shows bands in blue and violet (Gernæ, *C. Z.* 74, 803). S. ( $0^\circ$ ) about  $200^\circ$ .

**Preparation.**—Precipitated  $\text{HgO}$  is heated to about  $300^\circ$  for some time, and cooled (elouze, *A.* 46, 195); it is placed in a long tube surrounded by water; well washed and thoroughly dried Cl is passed through the tube. The reaction is  $\text{HgO} + 2\text{Cl}_2 = \text{HgCl}_2 + \text{Cl}_2\text{O}$ , the  $\text{Cl}_2\text{O}$  is passed into dry flasks; as each is filled it is closed with a glass stopper which is then

covered with paraffin. If liquid  $\text{Cl}_2\text{O}$  is required the tube containing  $\text{HgO}$  is connected with a Y tube, the upper part of which is cooled to at least  $-20^\circ$ . Ladenburg (*B. 17, 157*) recommends cooling by alcohol, the temperature of which is reduced to  $-40^\circ$  by a small ammonia-freezing machine—dry test tubes surrounded by ice and salt are placed under the Y tube, and a few drops of  $\text{Cl}_2\text{O}$  are collected in each tube. In this way the principal reactions of liquid  $\text{Cl}_2\text{O}$  may be demonstrated without danger (v. Ladenburg, *l.c.*). If crystalline  $\text{HgO}$  is used, no action occurs between it and  $\text{Cl}_2$ ; if ordinary *ppd.*  $\text{HgO}$  is employed the action is too rapid, much heat is evolved, and no  $\text{Cl}_2\text{O}$ , but only  $\text{O}$ , is obtained.

**Properties.**—Reddish-yellow gas, with very irritating odor; condenses at about  $-20^\circ$  to a blood-red liquid which boils at about  $-17^\circ$  (Pelouze, *A. Ch. [3] 7, 176*). Both gas and liquid are very easily decomposed, sometimes with violent explosion, into  $\text{Cl}$  and  $\text{O}$ ; pouring the liquid from one glass vessel to another, or contact with a scratch on the glass, may suffice to bring about an explosion. Rise of temperature, or the action of electric sparks, causes the gas to explode, with production of  $\text{Cl}$  and  $\text{O}$  (Balard, *A. Ch. 57, 225*; Gay-Lussac, *C. R. 14, 927*). The gas is said to decompose in sunlight without explosion into  $\text{Cl}$  and  $\text{O}$ , the volumes of these gases being as 2:1.

**Reactions and Combinations.**—1. Powdered metals form chlorides and oxides, or oxychlorides, frequently with explosion.—2. Many metallic oxides react with the gas to form chlorides and higher oxides;  $\text{Ag}_2\text{O}$  gives  $\text{AgCl}$  and  $\text{O}$ .—3. Phosphorus, Sulphur, and Selenium, form chlorides and oxides, with explosion.—4. Hydrogen, in sunlight, decomposes the gas explosively, producing  $\text{HCl}$  and  $\text{H}_2\text{O}$ .—5. Freshly heated carbon, cooled under  $\text{Hg}$ , detonates in  $\text{Cl}_2\text{O}$ ,  $\text{Cl}$ ,  $\text{O}$ , and a little  $\text{CO}_2$  are formed.—6. Hydrochloric acid gas forms  $\text{H}_2\text{O}$  and  $\text{Cl}$ .—7. Acetic anhydride,  $(\text{C}_2\text{H}_3\text{O})_2\text{O}$ , absorbs the gas forming the very unstable compound  $\text{C}_2\text{H}_3\text{O}_2\text{OCl}$  (Schützenberger, *C. R. 53, 538*).—8. The liquid  $\text{Cl}_2\text{O}$  sinks in water, and then slowly dissolves forming  $\text{HClO}_2\text{Aq}$  (*q. v.*). Water at  $0^\circ$  absorbs more than 200 times its volume of gaseous  $\text{Cl}_2\text{O}$ ; the solution contains  $\text{HClO}$ .

**Method of Analysis.** The gas was slowly passed through a narrow glass tube with three bulbs blown on it, the part of the tube before the first bulb being heated; by this means the gas was decomposed, and the three bulbs were filled with the products of this decomposition, viz.,  $\text{Cl}$  and  $\text{O}$ . The bulbs were sealed by the blowpipe, and each was then opened under  $\text{KOH Aq}$ ; the  $\text{Cl}$  was thus absorbed while the  $\text{O}$  remained. The volume of  $\text{KOH Aq}$  was measured; the bulbs were filled with  $\text{KOH Aq}$  and the total volume was determined. The result was that 2 vols.  $\text{Cl}$  were found in each bulb with 1 vol.  $\text{O}$ . The weights of  $\text{Cl}$  and  $\text{O}$  formed were calculated, and the weight of the volume of the undecomposed gas which the bulb would contain when full was calculated from the observed S.G. of the gas. It was thus found that 2 vols. of the gas are decomposed by heat into 2 vols.  $\text{Cl}$  and 1 vol.  $\text{O}$ . This calculation assumes that the gas entering the small bulb contains no free  $\text{Cl}$  or  $\text{O}$  (Regnault).

**References.**—Berthollet, *Statique Chimique*, 2, 183. Wagemann, *C. A. 55, 115*. Geiger, *R. P. 15, 40*. Grouvelle, *A. Ch. 17, 87*. Berzelius, *P. 12, 529*. Liebig, *P. 15, 541*. Soubeiran, *A. Ch. 48, 113*. Balard, *A. Ch. 57, 225*. Martens, *A. Ch. 61, 193*. Gay-Lussac, *C. R. 14, 927*. Pelouze, *A. Ch. [3] 7, 176*. Kolb, *A. Ch. [4] 12, 266*.

**II. CHLORINE PEROXIDE.  $\text{ClO}_2$ .** (*Chlorine dioxide or tetroxide*.) Mol. w. 37.29. V.D. 38.5, 34.5 at  $10.7^\circ$  and 718 mm. (Pebal a. Schacherl, *A. 213, 113*). S.G. 2.315 (air = 1).

**Preparation.**—1. About 100 grams pure conc.  $\text{H}_2\text{SO}_4$  is placed in a platinum dish surrounded by snow and salt; from 15 to 20 grams dry finely powdered  $\text{KClO}_3$  is added little by little, with stirring with a glass rod after each addition. When so much  $\text{KClO}_3$  has been added that the contents of the dish form a thick oily liquid, this is carefully poured through a funnel into a glass flask, with the neck drawn out, of a size such that it is not more than one-third filled with the liquid. The greatest care must be taken to keep the neck of the flask perfectly free from the oily liquid. The flask is kept cold; a piece of glass tubing of the same diameter as the end of the drawn-out neck of the flask is pressed closely against the end of this neck, and the joint is made tight by caoutchouc. The flask is then placed in a water bath and very slowly heated to  $20^\circ$ , and after some time to  $30^\circ$ – $40^\circ$ ; the gas is collected, by downward displacement, in small dry flasks, or it may be liquefied by passing into small tubes surrounded by snow and salt. The whole operation is best conducted by gas-light (Millon, *J. pr. 29, 401*; Cohn, *J. pr. 83, 54*). If the liquid is prepared each tube should not contain more than 1 or 2 drops; the liquid is frightfully explosive. The gas prepared as above always contains a little  $\text{Cl}$  and  $\text{O}$ .—2. According to Jacquelin (*A. Ch. 30, 339*) fairly pure  $\text{ClO}_2$  may be obtained by the action of a mixture of equal volumes of conc.  $\text{H}_2\text{SO}_4$  and water on pure  $\text{KClO}_3$ , in a flask with a long neck, placed in water at  $70^\circ$  so that half the neck is immersed.—3. If a very intimate mixture of 3 pts. finely powdered  $\text{KClO}_3$  with 13 pts. finely powdered crystallised oxalic acid is warmed in an oil bath to  $70^\circ$  a mixture of  $\text{ClO}_2$  and  $\text{CO}_2$  is evolved regularly and without danger; five-sixths of the  $\text{Cl}$  of the  $\text{KClO}_3$  forms  $\text{ClO}_2$ , and one-sixth remains as  $\text{KCl}$  (Calvert a. Davies, *C. J. 11, 193*; v. also Schacherl, *A. 206, 75*).

**Properties.**—Yellowish-green gas, condensing (by snow and salt) to a red-brown liquid, and solidifying at about  $-59^\circ$  (ether and solid  $\text{CO}_2$  in *vacuo*) to hard, brittle crystals, resembling  $\text{K}_2\text{Cr}_2\text{O}_7$  in appearance (Faraday, *T. 1845, 155*). Both gas and liquid are frightfully explosive; explosions often occur without any assignable cause. S.G. of liquid  $\text{ClO}_2$  about 1.5. B.P. about  $9^\circ$  (Pebal, *A. 177, 1*). In a vessel wholly made of glass, liquid  $\text{ClO}_2$  boils at  $9.9^\circ$  under pressure of 780 mm. without explosion (Schacherl, *A. 204, 68*). The gas has an irritating odour, resembling that of  $\text{NO}_2$ ; it does not affect litmus paper; it is unchanged in the dark, but decomposes, usually explosively, in sunlight.

**Reactions and Combinations.**—1. Easily ox-

dried bodies, e.g. P, or S, burn in  $\text{ClO}_2$ , usually with explosion.—2. *Mercury* absorbs the gas and decomposes it with detonation.—3. *Hydrogen* (8 vols. H + 3 vols.  $\text{ClO}_2$ ) decomposes  $\text{ClO}_2$  explosively in presence of spongy Pt, or of electric sparks, forming  $\text{H}_2\text{O}$  and  $\text{HCl}$  (Blundell, *P.* 2, 216; Stadion, *G. A.* 52, 197 a. 339).—4. According to Kämmerer (*P.* 138, 404) *bromine* and *iodine* do not react with gaseous  $\text{ClO}_2$ .—5. Many *organic compounds* cause explosion of  $\text{ClO}_2$  at ordinary temperatures.—6. Liquid  $\text{ClO}_2$  explodes when a piece of *potash* is placed in it; if water is present, a mixture of equal equivalents of  $\text{KClO}_3$  and  $\text{KClO}_4$  is formed, much heat being produced.—7. Liquid  $\text{ClO}_2$  sinks in water; on shaking, much gas is given off, an explosion usually takes place, and the water contains  $\text{HClO}_2$  and  $\text{HClO}_3$ . If the water is kept at 0° yellow crystals are formed which cannot be melted without evolution of considerable quantities of gas (Millon, *A. Ch.* [3] 7, 298). Water at 4° absorbs about 20 times its own volume of gaseous  $\text{ClO}_2$ , with formation of  $\text{HClO}_2\text{Aq}$  and  $\text{HClO}_3\text{Aq}$  (Millon, *l.c.*); this solution decomposes in sunlight, giving off Cl and O, and after a time only  $\text{HClO}_2$  remains in solution.—8. Conc. *sulphuric acid* at -18° absorbs about 20 times its own volume of gaseous  $\text{ClO}_2$ , becoming yellow in colour; on removing the acid from the freezing mixture the colour changes to reddish; at 10°-15°  $\text{ClO}_2$ ,  $\text{Cl}_2\text{O}$  (?), and a mixture of Cl and O in the proportion of 2 vols. to 3 vols., are evolved; when gas ceases to come off, the residue contains  $\text{HClO}_2$  (Stadion, *G. A.* 52, 197 a. 333; Millon, *A. Ch.* [3] 7, 298).

*Method of Analysis.*—(Pebal, *A.* 177, 1; 213, 112). The gas was prepared by gently warming  $\text{H}_2\text{SO}_4\text{Aq}$  (1 vol. conc. acid to 2 vols. water) with a mixture of oxalic acid and potassium chlorate; it was washed by passing through a little water, dried by  $\text{CaCl}_2$ , and liquefied in a small glass bulb with two glass necks surrounded by  $\text{CaCl}_2$  and snow. When about 3 c.c. of the liquid were obtained, the evolution of gas was stopped; one neck of the glass bulb was closed, and the other was connected with a glass tube, furnished with glass stop-cocks, placed in water. The freezing mixture was removed, and gaseous  $\text{ClO}_2$  was allowed to pass slowly through the glass tube till all air was removed; the stop-cocks of the tube were then closed, and the temperature of the water and the reading of the barometer were determined. The glass tube full of  $\text{ClO}_2$  was surrounded by fine wire gauze (in case an explosion should occur), and the water was gently warmed until decomposition of the gas occurred; the temperature of the water was then allowed to come back to the first reading. The mixed gases, or a portion of them, were then transferred to a similar graduated glass tube, filled with saturated  $\text{NaClAq}$  containing a little  $\text{ClAq}$  and placed in a cylinder full of the same solution; this solution absorbs hardly any Cl from a mixture of Cl and O. The volume of Cl in the known volume of the mixed gases was determined by absorption by  $\text{KIaAq}$ . The following results were obtained:

- (1) Volume - expansion on decomposition  
28.9:36.44 = 2:3.05;

- (2) Ratio of Cl-volume to O-volume 11.1:28.7  
= 1:2.09;

- (3) Ratio of O-volume to expansion  
24.65:12.54 = 1:96.1;

that is, 2 vols. chlorine peroxide yields 2 vols. O and 1 vol. Cl. Then from the weights of O and Cl obtained, and the weight of chlorine peroxide used (calculated from the observed S.G. of the three gases) the formula  $\text{ClO}_2$  is deduced. It is possible that the gas at low temperatures, or the liquid, may have the composition  $\text{Cl}_2\text{O}_3$ .  $\text{ClO}_2$  may also be analysed by allowing the liquid to act on  $\text{FeSO}_4\text{Aq}$  and determining the  $\text{Fe}_2\text{SO}_4$  and the  $\text{HCl}$  produced;

Davies, *C. J.* 11, 193. Cohn, *J. pr.* 85, 53. Faraday, *T.* 1845, 155. Blundell, *P.* 2, 216. Kämmerer, *P.* 138, 404. Pebal, *A.* 177, 1. Garzaroli-Thurnlackh, *A.* 209, 184.

III. CHLORINE TRIOXIDE,  $\text{Cl}_2\text{O}_3$ . (*Chlorous anhydride*.) The existence of this body is very doubtful. The results obtained by Millon, Carius, Schiel, &c. differed considerably: thus Millon could not liquefy the gas he obtained; Schiel and others obtained a dark reddish-brown liquid by passing the gas into a tube in snow and salt. Brandau determined the S.G. of the gas to be 4.07 at 9°, 4.02 at 13°, and 3.17 at 16°; Millon gave the S.G. as 2.65 and Schiel as 2.6-2.73. (The calculated S.G. of  $\text{Cl}_2\text{O}_3$  is 4.109, air=1.) The gas was analysed by Millon by passing it over hot Cu and determining the  $\text{CuCl}_2$  formed; Brandau dissolved in water and titrated with  $\text{KIaAq}$ ; he also reduced by  $\text{HNO}_3\text{Aq}$  and estimated the Cl. The results cannot be regarded as satisfactory. Garzaroli-Thurnlackh (*B.* 14:28; more fully, *A.* 209, 194) in 1881 determined the relation between the expansion of the gas on decomposing it by heat and the volume of O thus obtained; he employed Pebal's method for analysis of  $\text{ClO}_2$  (*q. v.*); the gas examined was prepared by the action of (1)  $\text{KClO}_3$  and  $\text{HNO}_3\text{Aq}$  on  $\text{As}_2\text{O}_3$  (Millon's method), (2)  $\text{KClO}_3$  and  $\text{H}_2\text{SO}_4\text{Aq}$  on  $\text{C}_2\text{H}_6$  (Carius's method modified by Brandau), (3)  $\text{KClO}_3$  and  $\text{HNO}_3\text{Aq}$  on sugar (Schiel's method). In every case the volume of O obtained was almost exactly double the total expansion of the gas; but if the gas were  $\text{Cl}_2\text{O}_3$ , the volume of O must be equal to the total expansion, and this result would hold good if free Cl were mixed with the  $\text{Cl}_2\text{O}_3$ . Garzaroli-Thurnlackh concludes that the gas supposed to be  $\text{Cl}_2\text{O}_3$  by Millon and Brandau was really a mixture of  $\text{ClO}_2$  with varying quantities of Cl, a little O, and  $\text{CO}_2$ .

*Preparation of compound said to be  $\text{Cl}_2\text{O}_3$ .*—1. Millon (*A. Ch.* [3] 7, 298) used 15 pts. finely-powdered  $\text{As}_2\text{O}_3$  and 20 pts. powdered  $\text{KClO}_3$  made into a thin cream with water; to this he added 60 pts. pure  $\text{HNO}_3\text{Aq}$  (free from  $\text{HCl}$  and  $\text{H}_2\text{SO}_4$ ) S.G. 1.33, diluted with 20 pts.  $\text{H}_2\text{O}$ ; the mixture was placed in a flask of a size such that the liquid partly filled the neck, an exit tube was attached, and the contents

gradually warmed in a water-bath to about 25°. The gas may be dried by  $\text{CaCl}_2$ ; it is collected in dry flasks by downward displacement. The flask should be covered with a thick cloth in case of explosion. Slight explosions sometimes occur, but if the process is conducted carefully it is attended with danger.—2. Schmel (A. 109, 319) used a mixture of 2 pts.  $\text{KClO}_3$ , 6 to 8 pts. cane sugar, and 8 pts.  $\text{HNO}_3$  Aq. S.G. 1.3 diluted with 3-4 pts.  $\text{H}_2\text{O}$ ; the gas contained  $\text{CO}_2$ .—3. Carius (A. 140, 317; v. also Brandau, A. 151, 63) dissolved 10 pts.  $\text{C}_2\text{H}_4$  in 100 pts. conc.  $\text{H}_2\text{SO}_4$  diluted with 100 pts.  $\text{H}_2\text{O}$ , after cooling added 12 pts. powdered  $\text{KClO}_3$ , and heated to about 50° on a water-bath. The exit tube of the flask was connected with a series of small bulbs containing water; from these the gas passed into a tube kept at -18°; the liquefied oxide was separated from crystals of hydrated chloric acid (q. v.). About 5-7 c.c. liquid was obtained from 54 grams  $\text{KClO}_3$ ; the liquid contained a little water and traces of  $\text{ClO}_2$  and  $\text{HClO}_2$ .

*Properties of the supposed compound.*—The properties said to belong to  $\text{Cl}_2\text{O}$  resemble those which characterise  $\text{ClO}_2$ ; the former is however less explosive. It is described as a greenish-yellow gas, condensing to a dark red-brown liquid; S.G. about 1.5; the liquid volatilises at about 0°, the latter portions boiling at 8°-9°. The gas is decomposed into  $\text{Cl}$  and  $\text{O}$  at about 57° with slight explosion. In contact with most non-metals, and with  $\text{Te}$  and  $\text{As}$  detonation occurs.  $\text{Pb}$ ,  $\text{Cu}$ ,  $\text{Sn}$ ,  $\text{Sb}$ ,  $\text{Ag}$ ,  $\text{Zn}$ , and  $\text{Fe}$  are unchanged in the gas;  $\text{Hg}$  absorbs it. One volume  $\text{H}_2\text{O}$  absorbs 8 vols. of the gas at 8°; the solution contains  $\text{HClO}_2$ , and after a time also  $\text{HClO}$ . Brandau says that if the water is at 0°, a solid hydrate of  $\text{HClO}_2$  containing from 50 to 67.5 p.c.  $\text{H}_2\text{O}$  is produced.

**CHLORINE, OXY-ACIDS OF.**—Four compounds are known,  $\text{HClO}$ ,  $\text{HClO}_2$ ,  $\text{HClO}_3$ , and  $\text{HClO}_4$ . The anhydride of  $\text{HClO}$ , viz.  $\text{Cl}_2\text{O}$ , is known; the anhydride of  $\text{HClO}_2$ , viz.  $\text{Cl}_2\text{O}_3$ , is generally stated to be known, but the evidence is not conclusive (v. CHLORINE TRIOXIDE). Of the acids, only  $\text{HClO}$  has been obtained in definite form apart from water. Aqueous solutions of  $\text{HClO}$  and  $\text{HClO}_2$  are easily decomposed on heating, giving  $\text{HClO}_3$  Aq. and  $\text{HClAq}$ ; the most conc. solution of  $\text{HClO}_3$  Aq. obtained contains the acid and water in the ratio  $\text{HClO}_3 : \text{H}_2\text{O}$ , this solution decomposes on heating yielding  $\text{HClO}_3$  Aq,  $\text{Cl}$ , and  $\text{O}$ ;  $\text{HClO}_3$  Aq is stable, it may be concentrated by distillation until crystals of  $\text{HClO}_3 \cdot \text{H}_2\text{O}$  are obtained; by carefully heating these crystals the acid  $\text{HClO}_3$  is formed, this acid is very easily decomposed with explosion. The following thermal data are given by Thomsen (Th. 2, 400):—

$[\text{Cl}_2\text{Cl}_2\text{Aq}] = 39,315$	Diff. = -9,385
$[\text{H}_2\text{Cl}_2\text{O}_3\text{Aq}] = 29,930$	
	Diff. = -5,990
$[\text{H}_2\text{Cl}_2\text{O}_4\text{Aq}] = 23,940$	

These numbers would lead us to expect that neither  $\text{HClO}_3$  Aq nor  $\text{HClO}_4$  Aq would be produced by the direct addition of  $\text{O}$  to  $\text{HClAq}$ ; nor should we expect to form  $\text{KClO}_3$  Aq by adding  $\text{O}$  to  $\text{KClAq}$ , for  $[\text{KClO}_3\text{O}^*] = -15,370$  (Thomsen); the production of  $\text{HClO}_3$  Aq by the direct combination of  $\text{Cl}$  and  $\text{O}$  in presence of  $\text{H}_2\text{O}$  is also improbable, considering that  $[\text{Cl}_2\text{O}_3\text{Aq}] = -8,490$  (Thomsen).  $\text{Cl}$  and  $\text{O}$  do not unite directly, but if a moderately basic oxide, e.g.  $\text{HgO}$  or  $\text{ZnO}$ , is acted on by  $\text{Cl}$  and  $\text{H}_2\text{O}$ ,  $\text{HClO}_3$  is produced; if a strongly basic oxide, e.g.  $\text{K}_2\text{O}$  or  $\text{Na}_2\text{O}$ , is used, a salt of  $\text{HClO}_3$  is formed in solution. Odling (Ph. [2] 1, 469) says that  $\text{HClO}_3$  Aq is formed when a current of air laden with  $\text{HCl}$  is passed into a warm solution of  $\text{K}_2\text{Mn}_2\text{O}_8$  containing  $\text{H}_2\text{SO}_4$ .  $\text{HClO}_3$  Aq is also said to yield  $\text{HClO}_4$  Aq by the action of ozone. In the ordinary processes whereby  $\text{HClO}_3$  Aq and  $\text{HClO}_4$  Aq are obtained from  $\text{HClO}_3$  (or salts of the higher acids from salts of  $\text{HClO}$ ) much heat is produced in the decomposition of the lower acid, or salt, and  $\text{O}$  is set free at the same time; under these conditions the higher acids, or salts, are formed. When  $\text{KClO}_3$  Aq is heated  $\text{KClAq}$  and  $\text{KClO}_4$  Aq are produced; when  $\text{KClO}_3$  is heated,  $\text{O}$  is evolved and  $\text{KClO}_4$  and  $\text{KCl}$  are produced; on raising the temperature  $\text{KCl}$  remains and all the  $\text{O}$  is evolved. Thomsen (Th. 2, 145) gives the following thermal values for the possible reactions between  $\text{Cl}$  and  $\text{K}_2\text{O}$ :—

$$[\text{Cl}^*, 3\text{K}^*\text{O}^*\text{Aq}] = \begin{cases} 73,335 & \text{if } 3\text{KClO}_3\text{Aq} + 3\text{KClAq} \\ 97,945 & \text{if } \text{KClO}_4\text{Aq} + 5\text{KClAq} \\ 113,315 & \text{if } 3\text{O} + 6\text{KClAq} \end{cases}$$

are formed.

Chloric acid is as strong an acid, i.e. its affinity is as great, as hydrochloric acid (v. AFFINITY, vol. i. pp. 82, 83) (comp. BROMINE, OXY-ACIDS OF, v. also HALOGEN ELEMENTS).

*Detection and Estimation of salts of  $\text{HClO}$ ,  $\text{HClO}_2$ ,  $\text{HClO}_3$ , and  $\text{HClO}_4$ .*

I. Salts of  $\text{HClO}$  in solution react as oxidisers much in the same way as  $\text{ClAq}$ ; on adding a little extremely dilute  $\text{HNO}_3$  Aq and distilling, a dilute solution of  $\text{HClO}_3$  Aq is obtained which (1) bleaches indigo at once, but does not bleach if  $\text{As}_2\text{O}_3$  Aq is present, (2) gives a brownish pp. of  $\text{HgO} \cdot \text{HgCl}_2$ , when shaken with  $\text{Hg}$ , (3) with  $\text{SO}_2$  Aq forms a solution containing 1 equivalent  $\text{HCl}$  to 2 equivalents  $\text{H}_2\text{SO}_4$  ( $\text{HClO}_3\text{Aq} + \text{SO}_2\text{Aq} + \text{H}_2\text{O} = \text{H}_2\text{SO}_4\text{Aq} + \text{HClAq}$ ). Hypochlorites may be estimated by titration with  $\text{KI}$  Aq and  $\text{Na}_2\text{S}_2\text{O}_3$  Aq.

II. Salts of  $\text{HClO}_2$  in solution react very much as mixtures of chlorates and chlorides; they are decomposed by  $\text{H}_2\text{SO}_4$  Aq (1 acid to 8-10 water) with formation of a yellow colour probably due to  $\text{ClO}_2$  and  $\text{Cl}$ , whereas a mixture of chloride and chlorate is not decomposed. They bleach acidulated indigo at once even in presence of  $\text{As}_2\text{O}_3$  Aq. With  $\text{SO}_2$  Aq a solution is formed containing  $\text{HCl}$  and  $\text{H}_2\text{SO}_4$  in the ratio  $\text{HCl} : 2\text{H}_2\text{SO}_4$  ( $\text{HClO}_2\text{Aq} + 2\text{SO}_2\text{Aq} + 2\text{H}_2\text{O} = 2\text{H}_2\text{SO}_4\text{Aq} + \text{HClAq}$ ). \*Chlorites may be estimated by allowing them to oxidise a standardised acidulated solution of  $\text{FeSO}_4$ , and determining the residual  $\text{FeSO}_4$  by  $\text{K}_2\text{Mn}_2\text{O}_8$  Aq.

III. Salts of  $\text{HClO}_3$  in solution do not bleach acidulated indigo solution in the cold until a little  $\text{SO}_2$  Aq is added ( $\text{Cl}$  is then set free);

they do not separate I at once from KIAq. They are decomposed by digestion with warm conc. HClAq; salts of HClO<sub>2</sub> are not. Chlorates may be estimated by reduction to chlorides, by Zn and H<sub>2</sub>SO<sub>4</sub>Aq, or by a Cu-Zn couple (v. Botherhamley and Thompson, C. J. 53, 159). They may be separated from chlorites by conversion into K salts, and repeated evaporation *in vacuo* (v. CHLOROUS ACID AND CHLORITES). KClO<sub>2</sub> is fairly soluble in water at 15° (S=6), and KClO<sub>3</sub> is nearly insoluble (S=1.6); KClO<sub>4</sub> is insoluble in alcohol containing a little K.C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>; a method of separation of KClO<sub>2</sub> and KClO<sub>3</sub> may be based on these facts.

IV. Salts of HClO<sub>4</sub> are not decomposed by digestion with conc. HClAq at 100°; their solutions do not bleach acidulated indigo even in presence of SO<sub>2</sub>Aq, nor are they reduced by a Cu-Zn couple at 100°. Perchlorates may be estimated by converting them into KClO<sub>4</sub>, and determining the O in them by heating, and the K and Cl in the residue by the usual methods.

I. HYPOCHLOROUS ACID AND HYPOCHLORITES. HClOAq; MClOAq. In 1788 Berthollet obtained a liquid with bleaching properties by the action of chlorine on aqueous alkalis; Berthollet thought the liquid contained a compound of the alkali and chlorine, the latter being then regarded as oxidised hydrochloric acid. Berzelius supposed that a mixture of alkali chloride and chlorite was formed. In 1834 Balard proved that the bleaching liquid contained a salt of a new acid (Berthollet, *Statique Chimique*, 2, 183; Berzelius, P. 12, 529; Balard, A. Ch. 57, 225). The acid is known only in aqueous solutions; one salt Ca(ClO)<sub>2</sub>.xH<sub>2</sub>O has been obtained as a solid.

**Formation.**—1. By the action of Cl on ZnO in presence of water; ZnCl<sub>2</sub>Aq is formed at the same time.—2. By the action of Cl on (1) CaCO<sub>3</sub> suspended in water; (CaCO<sub>3</sub> + H<sub>2</sub>O + Aq + 2Cl<sub>2</sub> = CaCl<sub>2</sub>Aq + 2HClOAq + CO<sub>2</sub>):

(3) Na<sub>2</sub>SO<sub>4</sub>Aq; (Na<sub>2</sub>SO<sub>4</sub>Aq + H<sub>2</sub>O + Cl<sub>2</sub> = NaHSO<sub>4</sub>Aq + NaClAq + HClOAq).—3. By the action of Cl on AgCO<sub>3</sub> suspended in water; AgCl is also formed.—4. By the action of Cl on CaO.H<sub>2</sub>Aq; CaO<sub>2</sub>Cl<sub>2</sub> and CaCl<sub>2</sub> are probably formed (v. p. 17); when to an aqueous solution of this product as much very dilute HNO<sub>3</sub>Aq is added as suffices to convert less than the half of the Ca into Ca<sub>2</sub>NO<sub>2</sub>, and the liquid is distilled, dilute HClOAq is obtained (Gay-Lussac, A. 43, 153; Schorlemmer, B. 6, 1509; Kopfer, C. J. [2] 13, 713).—5. By passing Cl<sub>2</sub> into H<sub>2</sub>O, HClOAq is formed (v. CHLORINE MONOXIDE).—6. Addition of H<sub>2</sub>O<sub>2</sub>Aq (containing 2.45 p.c. H<sub>2</sub>O<sub>2</sub>) to a large excess of ClAq produces HClOAq, according to Fairley (B. A. 1874, 57); if much H<sub>2</sub>O<sub>2</sub> is added, the HClOAq is decomposed forming HClAq, H<sub>2</sub>O, and evolving O.—7. According to Odling (J. 1860, 65) HClOAq is formed by leading air laden with HCl into a warm solution of K<sub>2</sub>Mn<sub>2</sub>O<sub>8</sub> containing H<sub>2</sub>SO<sub>4</sub>Aq, or into a mixture of MnO<sub>2</sub> and H<sub>2</sub>SO<sub>4</sub>Aq.—8. HClOAq is also formed, along with other salts, by the action of Cl on aqueous solutions of Na<sub>2</sub>HPO<sub>4</sub>, FeSO<sub>4</sub>, ZnSO<sub>4</sub>, MnSO<sub>4</sub>, CuSO<sub>4</sub>,

Zn(C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>)<sub>2</sub>.—9. Alkali salts of HClO<sub>2</sub> are produced by electrolysis of NaClAq or KClAq (Lidoff, A. Tichomiroff, J. R. 1882, 212).

**Preparation.**—A flask of somewhat under 1000 c.c. capacity, with a good-fitting glass stopper, is filled with air-free Cl in the dark, ppd. HgO, which has been heated to 300° and cooled, suspended in a little H<sub>2</sub>O, is added, in the proportion of 15 grams to 1 litre Cl; the flask is shaken for about 15 minutes, and the liquid is poured off from the Hg<sub>2</sub>OCl<sub>2</sub> formed; this solution contains from 2 to 3 p.c. of HClO (Carius, A. 126, 196). If the Cl used contains much air the reaction proceeds very slowly; if the HgO has not been heated to 300° much Hg<sub>2</sub>Cl<sub>2</sub> is formed. 2HgO + 2Cl<sub>2</sub> + H<sub>2</sub>O + Aq = Hg<sub>2</sub>O.HgCl<sub>2</sub> + 2HClOAq. The solution of HClOAq is best kept in contact with a little HgO; any Cl set free is thus continually converted into HClO.

**Properties.**—An aqueous solution of HClO smells like Cl<sub>2</sub>O. It is very easily decomposed into Cl and HClO<sub>2</sub>Aq; in sunlight this change proceeds rapidly, the more conc. the solution the more rapid is the decomposition, and traces of HClO<sub>2</sub> are also formed (Popper, A. 227, 161). A dilute solution of HClO may be distilled with partial decomposition, the distillate is richer in HClO; Gay-Lussac found that, on distilling a dilute solution to one-half, the distillate contained five-sixths of the total HClO (C. R. 14, 927). HClOAq is a monobasic acid; added to KOHAq or Ca(OH)<sub>2</sub>Aq, KClOAq or Ca(ClO)<sub>2</sub>Aq is formed. Thomsen gives the heat of neutralisation as (HClOAq, NaOHAq) = 9,980, which is about  $\frac{2}{3}$  of the value of the heat of neutralisation of one of the stabler monobasic acids (e.g. HCl, HClO<sub>2</sub>, HNO<sub>3</sub>), and is a little greater than the value for HSHA, viz., 7,740. HClOAq does not dissolve bases insoluble in water, nor does it decompose the carbonates of these bases.

**Reactions.**—1. HClOAq acts generally as an oxidiser; it easily parts with O while HClAq remains. Thus, As is rapidly oxidised with evolution of light; P, S, Se, Br, I are converted to H<sub>3</sub>PO<sub>4</sub>Aq, H<sub>2</sub>SO<sub>4</sub>Aq, &c., even by dilute HClOAq; lower oxides or salts are converted into higher, e.g. SO<sub>2</sub>Aq to H<sub>2</sub>SO<sub>4</sub>Aq, FeO to Fe<sub>2</sub>O<sub>3</sub>, As<sub>2</sub>O<sub>3</sub>Aq to As<sub>2</sub>O<sub>5</sub>Aq, FeSO<sub>4</sub>Aq to Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>Aq, FeCl<sub>2</sub>Aq and Fe<sub>2</sub>O<sub>3</sub>, MnSO<sub>4</sub>Aq to MnO<sub>2</sub>; sulphides yield sulphates, e.g. H<sub>2</sub>SAq gives H<sub>2</sub>SO<sub>4</sub>Aq and S; NH<sub>3</sub> gives N, H<sub>2</sub>O, and NH<sub>4</sub>ClAq; HCl forms H<sub>2</sub>O and Cl. The quantity of the acid expressed by the formula HClO oxidises the same mass of an oxide &c. as can be oxidised by Cl<sub>2</sub> in presence of H<sub>2</sub>O; thus

2. On many carbon compounds HClOAq acts partly as an oxidising, partly as a chlorinating agent; e.g. H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>Aq + HClOAq = 2CO<sub>2</sub> + H<sub>2</sub>O + HClAq. Some organic compounds combine with the acid: e.g. C<sub>2</sub>H<sub>5</sub> + 3HClOAq = C<sub>2</sub>H<sub>5</sub>Cl<sub>3</sub>(OH)<sub>3</sub>, C<sub>6</sub>H<sub>6</sub> + HClOAq = C<sub>6</sub>H<sub>5</sub>ClOH.—3. Indigo solution, and various other vegetable colours, are rapidly bleached by HClOAq; one formula-weight of HClO in solution exerts as great a bleaching action as Cl<sub>2</sub>. HClOAq = HClAq + O; Cl<sub>2</sub> + H<sub>2</sub>O = 2HCl + O.—4. HClOAq

is said to be oxidized to  $\text{HClO}_4$  by ozone (Fairley, B. A. 1874, 58).

Hypochlorites are very easily decomposed; even in dilute solutions boiling suffices to convert them into chlorides and chlorates, in concentrated solutions boiling produces chlorides and  $\text{O}$ . Their solutions are also decomposed by heating with  $\text{Co}_2\text{O}_3$ ,  $\text{CuO}$ ,  $\text{MnO}_2$ , &c.,  $\text{O}$  is evolved and chlorides remain; e.g.,  $\text{Ca}(\text{ClO})_2 + \text{Co}_2\text{O}_3 = \text{CaCl}_2 + \text{Co}_2\text{O}_3 + \text{O}$  ( $\text{CoO}$ , is perhaps formed and again reduced to  $\text{Co}_2\text{O}_3$  with evolution of  $\text{O}$ ; Winkler, J. pr. 98, 340). As  $\text{Ca}(\text{OCl})_2$  is formed by the action of  $\text{Cl}$  on  $\text{CaO}$ , it is easy to obtain  $\text{O}$  by leading  $\text{Cl}$  into strong warm milk of lime containing a little  $\text{Co}_2\text{O}_3$  ( $\text{Co}_2\text{NO}$ , is used). Solutions of  $\text{KClO}$  and  $\text{NaClO}$ , along with  $\text{KCl}$  and  $\text{NaCl}$ , are obtained by leading  $\text{Cl}$  into cold dilute  $\text{KOH}$  or  $\text{NaOH}$ . Solutions of hypochlorites bleach rapidly on addition of a little  $\text{HNO}_3$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{HCl}$ , or even  $\text{CO}_2$ ; these solutions act as oxidisers towards  $\text{P}$ ,  $\text{S}$ ,  $\text{I}$ , &c. As the hypochlorites are so easily decomposed it is difficult to obtain them, even in solution, free from chlorides. Kingzett (C. J. [2] 13, 404) obtained crystals of nearly pure calcium hypochlorite,  $\text{CaOCl}_2 \cdot x\text{H}_2\text{O}$ , by exhausting bleaching powder with cold  $\text{H}_2\text{O}$ , filtering, and placing the filtrate *in vacuo* over conc.  $\text{H}_2\text{SO}_4$ . The crystals very easily decomposed, even by drying *in vacuo*, with evolution of  $\text{Cl}$ . The greater part of the  $\text{Cl}$  was lost by heating the moist crystals to  $100^\circ$ , the residue probably contained chlorate, it also contained much carbonate. The crystals dissolved in  $\text{H}_2\text{O}$ ; this solution was decomposed by  $\text{CO}_2$  with evolution of most, but not all, of the chlorine. That an aqueous solution of bleaching powder contains  $\text{CaOCl}_2$  has been confirmed by O'Shea (C. J. 43, 422), who proved that when such a solution is diffused without a membrane the diffuse contains considerably less active  $\text{Cl}$  (i.e.  $\text{Cl}$  which is so combined with  $\text{Ca}$  and  $\text{O}$  that it is capable of bleaching), and the residue considerably more active  $\text{Cl}$  than the original liquid, in proportion to the  $\text{Cl}$  or  $\text{CaCl}_2$ ; that diffusion sufficed to render the diffused liquid relatively poorer in active  $\text{Cl}$  and richer in chloride.

**Bleaching powder.**— $\text{Cl}$  is absorbed by slaked lime and the product possesses strong bleaching properties. Gay-Lussac regarded bleaching powder as containing  $\text{CaCl}_2\text{O}$  and  $\text{CaCl}_2$  in the ratio  $\text{CaCl}_2\text{O}:\text{CaCl}_2$ . Odling Manual of Chem. 1, 56) suggested the composition  $\text{CaOClCl}$ , chiefly because bleaching powder is not deliquescent nor is  $\text{CaCl}_2$  removed from it by treatment with alcohol. Göpner J. pr. [2] 7, 441) asserted bleaching powder to be a compound of  $\text{CaO}$  with  $\text{Cl}$ , and to have the composition  $\text{CaOCl}_2$ . Stahlschmidt (B. 8, 869) suggested the composition  $\text{Ca.OH.OCl}$ . Bleaching powder prepared by the action of pure dry  $\text{Cl}$  on pure dry  $\text{Ca}(\text{OH})_2$  always contains some  $\text{Ca}(\text{OH})_2$ ; but the quantity of this is variable and can be much diminished by repeated treatment with dry  $\text{Cl}$ , the  $\text{Ca}(\text{OH})_2$  is not therefore an essential part of the bleaching compound (v. Kopfer, J. J. [2] 18, 718; O'Shea, C. J. 43, 422; Lunge a. Schäppi, D. P. J. 239, 63). That  $\text{CaCl}_2$  is not present as such in bleaching powder is shown by the facts that it is not deliquescent, that when treated with small successive quantities

of water the first washings contain much less  $\text{Cl}$  than would be the case were  $\text{CaCl}_2$  present in the liquid, and that in the presence of a little moisture almost the whole of the  $\text{Cl}$  can be removed from bleaching powder by the action of  $\text{CO}_2$  (Lunge a. Schäppi, D. P. J. 237, 63; v. also Lunge a. Naef, B. 18, 840).

The composition  $\text{CaOCl}_2$  assigned by Göpner to the bleaching compound in bleaching powder was disproved by the experiments of Kopfer (C. J. [2] 13, 718), who showed that when an extremely dilute mineral acid ( $\text{HCl}$ ,  $\text{HNO}_3$ , or  $\text{H}_2\text{SO}_4$ ) is added to a solution of bleaching powder, in quantity sufficient to saturate all the lime and the  $\text{Ca}(\text{OCl})_2$  present—calculated on the assumption that the active (bleaching)  $\text{Cl}$  exists as  $\text{Ca}(\text{OCl})_2$ —and the liquid is distilled, almost the theoretical quantity of  $\text{HClO}$  is obtained in the distillate. The formula  $\text{Ca.OH.OCl}$  given to the bleaching compound by Stahlschmidt assigns a limit to the amount of active  $\text{Cl}$ , i.e.  $\text{Cl}$  available for bleaching, in the powder: Stahlschmidt represents the formation of the bleaching powder thus— $\text{Ca}(\text{OH})_2 + 2\text{Cl}_2 = 2\text{Ca.OH.OCl} + \text{CaCl}_2 + 2\text{H}_2\text{O}$ . The strongest bleaching powder cannot therefore contain more than about 33 p.c. of available  $\text{Cl}$ ; but Lunge a. Schäppi (D. P. J. 237, 63) prepared bleaching powder containing 48.4 p.c. available  $\text{Cl}$ . Moreover, according to Stahlschmidt's view, when water acts on bleaching powder, the reaction is  $2\text{Ca.OH.OCl} = \text{Ca}(\text{OH})_2 + \text{CaOCl}_2$ ; therefore no bleaching powder can be represented as containing  $\text{CaOCl}_2$  and  $\text{CaCl}_2$  in a greater ratio to  $\text{Ca}(\text{OH})_2$  than 1:1. Now O'Shea (C. J. 43, 422) determined the ratio of  $\text{Ca}(\text{OCl})_2$  (supposing all available  $\text{Cl}$  to exist in this form):  $\text{CaCl}_2:\text{Ca}(\text{OH})_2$  in six samples of bleaching powder made from pure  $\text{Ca}(\text{OH})_2$ ; in 2 out of the 6 samples the ratio was  $3\text{CaOCl}_2:3\text{CaCl}_2:2\text{Ca}(\text{OH})_2$ . Finally O'Shea removed any  $\text{CaCl}_2$  present as such from various samples of bleaching powder, prepared from pure  $\text{Ca}(\text{OH})_2$ , by repeated treatment with alcohol, and determined the total  $\text{CaO}$ , the total  $\text{Cl}$ , and the available  $\text{Cl}$ , in the residue, i.e. in the bleaching compound; the results in every case were—(1)  $\text{CaO}:\text{total Cl}=1:2$ ; (2) available  $\text{Cl}:\text{total Cl}=1:2$ ; (3)  $\text{CaO}:\text{available Cl}=1:1$ .

Stahlschmidt's formula  $\text{Ca.OH.OCl}$  requires for (1) the ratio 1:1; for (2) 1:1; for (3) 1:1.

Gay-Lussac's formula  $\text{CaOCl}_2$  requires for (1) the ratio 1:2; for (2) 1:1; for (3) 1:2.

Odling's formula  $\text{CaOClCl}$  requires for (1) the ratio 1:2; for (2) 1:2; for (3) 1:1.

The experiments of Kingzett already referred to (v. *supra*) showed that when water acts on bleaching powder  $\text{CaOCl}_2$  is contained in the solution. There can be little doubt that the formula  $\text{Ca.OClCl}$  better expresses the composition and properties of the bleaching compound, in bleaching powder than any other formula yet suggested; and that the reaction which occurs when water is added to this compound is  $2\text{Ca.OClCl} + \text{Aq} = \text{CaOCl}_2 + \text{CaCl}_2 + \text{Aq}$ .

II. CHLOROUS ACID AND CHLORITES.  $\text{HClO}_2$  and  $\text{MClO}_2$ . Chlorous acid is known only in aqueous solution; it is indeed doubtful whether even a solution of  $\text{HClO}_2$  has been obtained free from  $\text{HClO}$ .  $\text{KClO}_2$  may be prepared by adding an aqueous solution of  $\text{ClO}_2$  of known strength to

the proper quantity of KOHAq, evaporating at  $45^{\circ}$ – $50^{\circ}$  in *vacuo*, separating from  $\text{KClO}_3$ , which crystallises out, repeating the evaporation and separation of  $\text{KClO}_3$ , then adding alcohol to the mother liquor, evaporating in *vacuo*, and collecting the second crop of crystals which form (Garzarolli-Thurnlackh a. J. Hayn, A. 209, 203).  $\text{HClO}_2$  Aq could not be obtained by the action of acids on this salt. When the gas obtained by acting on  $\text{KClO}_3$  with  $\text{HNO}_3$  Aq and  $\text{As}_2\text{O}_3$  is led into water, a yellowish-red acid solution is obtained, which on warming, or on exposure to sunlight, contains  $\text{HCl}$  and  $\text{HClO}_2$ . This solution when freshly prepared is generally supposed to be  $\text{HClO}_2$  Aq; but the experiments of Garzarolli-Thurnlackh (v. CHLORINE TRIOXIDE) render it almost certain that the gas obtained as above is a mixture of  $\text{ClO}_2$  and  $\text{Cl}_2$ , and that the solution contains both  $\text{HClO}_2$  and  $\text{HClO}$ .

The solution prepared as described reacts with many metals; e.g.  $\text{Hg}$  forms an oxychloride,  $\text{Cu}$  a mixture of  $\text{CuCl}$  and  $\text{Cu}(\text{ClO}_2)_2$ ,  $\text{Zn}$  and  $\text{Pb}$  form chlorides and probably chlorites, and finally chlorates; with the lower salts of  $\text{Sn}$ ,  $\text{Fe}$ ,  $\text{Hg}$ , &c., the solution reacts to form higher salts of these metals;  $\text{As}_2\text{O}_3$  Aq is not oxidised to  $\text{As}_2\text{O}_5$  Aq;  $\text{HCl}$  decomposes the solution forming  $\text{Cl}$  and  $\text{H}_2\text{O}$ ,  $\text{VIA}$  Aq gives  $\text{HCl}$  and  $\text{I}$ ;  $\text{HNO}_3$  Aq is oxidised to  $\text{HNO}_2$  Aq;  $\text{SO}_2$  Aq is oxidised to  $\text{H}_2\text{SO}_4$  Aq. According to Brandau (A. 151, 340) if the gas supposed to be  $\text{ClO}_2$  is led into  $\text{H}_2\text{O}$  at  $0^{\circ}$  a solid hydrate of  $\text{HClO}_2$  is obtained; when pressed between paper the hydrate is a lustrous mass remaining unmelted at  $10^{\circ}$ , and volatilisable without residue. Two specimens gave 60 and 67.5 p.c. water respectively.

**Chlorites.** Very few of these salts have been prepared. Potassium chlorite,  $\text{KClO}_2$ , prepared as above described, forms needles, which deliquesce after standing some time in the air. The silver and lead salts,  $\text{AgClO}_2$  and  $\text{Pb}(\text{ClO}_2)_2$ , are obtained by adding  $\text{AgNO}_3$  Aq and  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$  Aq respectively, to  $\text{KClO}_2$  Aq.  $\text{AgClO}_2$  crystallises from hot  $\text{H}_2\text{O}$  in greenish-yellow scales; it is slowly decomposed in direct sunlight;  $\text{SO}_2$  Aq rapidly reduces to  $\text{AgCl}$ ; dilute  $\text{H}_2\text{SO}_4$  Aq evolves a gas the colour and smell of  $\text{ClO}_2$ .  $\text{KClO}_2$  Aq quickly oxidises  $\text{FeSO}_4$  Aq;  $\text{KClO}_2$  mixed with  $\text{S}$  and rubbed ignites the  $\text{S}$ .  $\text{Pb}(\text{ClO}_2)_2$ , after washing with hot  $\text{H}_2\text{O}$  forms greenish-yellow scales; slightly soluble in hot  $\text{H}_2\text{O}$ ; reactions similar to those of  $\text{KClO}_2$ , soluble in KOHAq. This solution is reduced by  $\text{SO}_2$  Aq to  $\text{PbSO}_4$  and  $\text{PbCl}_2$  Aq (Garzarolli-Thurnlackh a. J. Hayn, A. 209, 203). • Millon (A. Ch. [3] 7, 296) described  $\text{Ba}(\text{ClO}_2)_2$  and  $\text{Sr}(\text{ClO}_2)_2$  as very soluble salts; probably the salts contained  $\text{Ba}$  and  $\text{Sr}(\text{ClO}_3)_2$ .

III. CHLORIC ACID AND CHLORATES.  $\text{HClO}_3$  Aq;  $\text{MClO}_3$ . An aqueous solution of  $\text{HClO}_3$  is formed when  $\text{ClO}_2$  Aq is exposed to sunlight, or is heated.  $\text{KClO}_3$  and  $\text{NaClO}_3$  are produced by electrolysis of  $\text{KCl}$  Aq and  $\text{NaCl}$  Aq respectively; carbon electrodes are employed (Lidoff a. Tichomiroff, J. R. 1882, 341).

**Preparation.**—1.  $\text{Ba}(\text{ClO}_3)_2$  is obtained by dissolving 3 pts. crystallised  $(\text{NH}_4)_2\text{SO}_4$  and 3 pts.  $\text{KClO}_3$  in 15 pts. hot  $\text{H}_2\text{O}$ , evaporating to a thin syrup, digesting for a day at a gentle heat with alcohol (80 p.c.), filtering from  $\text{K}_2\text{SO}_4$ ,

adding  $\text{BaO}$  Aq, evaporating, and crystallising (Wittstein; v. also Böttger, A. 57, 138). A weighed quantity of the crystals of  $\text{Ba}(\text{ClO}_3)_2$  is dissolved in  $\text{H}_2\text{O}$ ; a quantity of dilute  $\text{H}_2\text{SO}_4$  Aq exactly sufficient to pp. all the  $\text{Ba}$  as  $\text{BaSO}_4$  is added, little by little; the liquid is filtered—the filtrate must give no pp. either with  $\text{BaO}$  Aq or  $\text{H}_2\text{SO}_4$  Aq—and the filtrate is concentrated in *vacuo* over  $\text{H}_2\text{SO}_4$ .—2. Hot  $\text{KClO}_3$  Aq is decomposed by excess of  $\text{H}_2\text{SiF}_6$  Aq; after cooling, the liquid is filtered from  $\text{K}_2\text{SiF}_6$  and evaporated over  $\text{H}_2\text{SO}_4$  and  $\text{KOH}$  in *vacuo*; the excess of  $\text{H}_2\text{SiF}_6$  volatilises and  $\text{HClO}_3$  Aq remains.

**Properties.**—By evaporation in *vacuo* of dilute  $\text{HClO}_3$  Aq, a somewhat oily, colourless, strongly acid, liquid is obtained, with S.G. 1.282 at  $14^{\circ}$ ; according to Kämmerer this liquid contains  $\text{HClO}_3$  and  $\text{H}_2\text{O}$  in the ratio  $\text{HClO}_3 : 7\text{H}_2\text{O}$ ; the same chemist says, that if this liquid remains longer in *vacuo*, sudden evolution of  $\text{Cl}$  and  $\text{O}$  occurs, and  $\text{HClO}_3 \cdot 4\frac{1}{2}\text{H}_2\text{O}$  remains (P. 138, 390). The strongest solution of  $\text{HClO}_3$  does not solidify at  $-20^{\circ}$ .  $\text{HClO}_3$  Aq reddens litmus paper and then bleaches it; paper or linen soaked in fairly conc. acid and dried takes fire. Heated to about  $40^{\circ}$  the solution decomposes into  $\text{HClO}_3$  Aq,  $\text{Cl}$ ,  $\text{O}$ , and  $\text{H}_2\text{O}$  (Serullas, A. Ch. 45, 204 a. 270). Thomsen gives these thermal values  $[\text{HClO}_3 \cdot \text{O}^{\circ} \text{Aq}] = 23,940$ , but  $[\text{Cl}_2\text{O}^{\circ} \text{Aq}] = -20,480$ ;  $[\text{HClO}_3 \text{Aq, KOHAq}] = 13,760$ . The affinity of  $\text{HClO}_3$  Aq is equal to that of the strongest acids (v. AFFINITY, vol. C. pp. 82, 83).

**Reactions.**—1. Zinc and iron dissolve in  $\text{HClO}_3$  Aq with evolution of  $\text{H}$ .—2. Iodine is oxidised to  $\text{HIO}_3$  Aq.—3. Oxidisable oxygen compounds are converted into higher compounds, e.g.  $\text{SO}_2$  Aq gives  $\text{H}_2\text{SO}_4$  Aq,  $\text{Cl}$  and  $\text{H}_2\text{O}$ ;  $\text{H}_3\text{PO}_3$  Aq gives  $\text{H}_3\text{PO}_4$  Aq.—4. Chlorhydric acid forms  $\text{H}_2\text{O}$  and  $\text{Cl}$ .—5. Sulphuretted hydrogen produces  $\text{H}_2\text{SO}_4$  Aq and  $\text{S}$ .—6. Iodine gives  $\text{HIO}_3$  Aq; bromine only traces of  $\text{HBrO}_3$  Aq (Kämmerer, P. 138, 399).—7. By electrolysis  $\text{HClO}_3$  Aq yields first  $\text{HClO}_2$  Aq, and then  $\text{Cl}$  (Buff, A. 110, 237).—8. Heated above  $40^{\circ}$   $\text{HClO}_3$  Aq decomposes into  $\text{Cl}$ ,  $\text{O}$ ,  $\text{H}_2\text{O}$ , and  $\text{HClO}_2$  Aq.

**Chlorates.**  $\text{HClO}_3$  Aq acts as a monobasic acid. Normal chlorates are all soluble in water;  $\text{KClO}_3$  is less soluble than the others. Chlorates may be prepared by acting on  $\text{Ba}(\text{ClO}_2)_2$  Aq with the sulphate of the metal whose chlorate is required; many are also obtained by the action of the metallic oxide, or carbonate, on  $\text{HClO}_3$  Aq. Chlorates easily part with their  $\text{O}$  when heated; they act therefore as oxidisers (v. Potassium chlorate). • Aqueous solutions are not, however, very easily reduced (e.g.  $\text{H}_2\text{S}$  has no action); boiled with  $\text{P}$ , chlorides are formed (Slater, J. pr. 60, 247); chlorates in solution are also reduced by  $\text{Zn}$  and dilute  $\text{H}_2\text{SO}_4$  Aq and by a  $\text{Cu}$ - $\text{Zn}$  couple. Fusible chlorates detonate when rubbed with easily combustible bodies, e.g.  $\text{S}$  or  $\text{Sb}_2\text{S}_3$ ; sometimes violent explosions occur.  $\text{H}_2\text{SO}_4$  Aq decomposes chlorates with evolution of  $\text{ClO}_2$  and  $\text{Cl}$ ;  $\text{HCl}$  Aq evolves *esochlorine*, which is a mixture of  $\text{ClO}_2$  and  $\text{Cl}$ . Solutions of chlorates do not bleach; addition of a little  $\text{SO}_2$  Aq liberates  $\text{Cl}$  and bleaching occurs.

**Ammonium chlorate.**  $\text{NH}_4\text{ClO}_3$ . By adding  $\text{NH}_3$  Aq, or  $(\text{NH}_4)_2\text{CO}_3$  Aq, to  $\text{HClO}_3$  Aq; or  $(\text{NH}_4)_2\text{CO}_3$  Aq to  $\text{Ba}(\text{ClO}_2)_2$  Aq and filtering; or

( $\text{NH}_4$ ),  $\text{SiF}_6$  Aq to  $\text{KClO}_4$  Aq and filtering; the solution in each case is evaporated, the salt separates in needles. Soluble in  $\text{H}_2\text{O}$ , and alcohol; sublimates somewhat above  $100^\circ$ ; at higher temperature decomposes to  $\text{Cl}$ ,  $\text{N}_2\text{O}$ , and  $\text{H}_2\text{O}$ .

**Barium chlorate.** — By adding  $\text{BaCO}_3$  Aq, or  $\text{BaCO}_3$  to  $\text{HClO}_4$  Aq. Thompson (*A. M.* [3] 31, 510) mixes solutions, each in the minimum of water, of 122 parts  $\text{KClO}_4$  and 167 parts  $\text{NH}_4\text{H}_2\text{O}_2$ , removes  $\text{K}_2\text{CO}_3$ , adds alcohol, filters, decomposes the  $\text{NH}_4\text{ClO}_4$  Aq by boiling with freshly ppt.  $\text{BaCO}_3$ , filters and crystallises. (v. also Böttger, *A. 57*, 138; Brandau, *A. 151*, 361; Bolly a. Merz, *D. P. J.* 153, 358). Crystallises in 4-sided plates. S. ( $0^\circ$ ) 22.8; ( $40^\circ$ ) 52.1; ( $116^\circ$ ) 195; ( $135^\circ$ ) 287.4; ( $146^\circ$ ) 365.6; ( $180^\circ$ ) 522.6 (Tilden a. Shenstone, *T.* 175, 23).

**Calcium chlorate.**  $\text{Ca}(\text{ClO}_3)_2$ . Prepared like  $\text{Ba}(\text{ClO}_3)_2$ . Very deliquescent and difficult to crystallise.

**Copper chlorate.**  $\text{Cu}(\text{ClO}_3)_2 \cdot 6\text{H}_2\text{O}$ . By dissolving  $\text{CuO}$  in  $\text{HClO}_4$  Aq and evaporating. Green, deliquescent, octahedra; soluble in alcohol; decomposed at  $100^\circ$  probably forming a basic salt (Wächter, *A. 52*, 233; v. also Casselmann, *Fr. 4*, 24).

**Lead chlorate.**  $\text{Pb}(\text{ClO}_3)_2$ . By saturating  $\text{HClO}_4$  Aq with  $\text{PbO}$ , and evaporating; hot solutions deposit rhombohedral deliquescent  $\text{Pb}(\text{ClO}_3)_2 \cdot \text{H}_2\text{O}$  (Wächter, *A. 52*, 233).

**Magnesium chlorate.**  $\text{Mg}(\text{ClO}_3)_2$ . Obtained as, and closely resembles,  $\text{Ca}(\text{ClO}_3)_2$ .

**Mercury chlorates.** (1)  $\text{HgClO}_3$ ; columnar crystals, soluble in  $\text{H}_2\text{O}$  and alcohol; by dissolving  $\text{Hg}_2\text{O}$  in  $\text{HClO}_4$  Aq; heated, gives  $\text{HgCl}$ ,  $\text{Hg}$ , and  $\text{O}$ . (2)  $\text{Hg}(\text{ClO}_3)_2$ , crystallises from solution of  $\text{HgO}$  in warm  $\text{HClO}_4$  Aq in needles. S. (about  $15^\circ$ ) 25. Decomposed by heat to  $\text{O}$ ,  $\text{HgCl}$ ,  $\text{HgCl}_2$ , and a little  $\text{HgO}$ .

**Potassium chlorate.**  $\text{KClO}_3$ . By passing  $\text{Cl}$  into warm milk of lime containing  $\text{KCl}$ , and crystallising from the more soluble  $\text{CaCl}_2$ ; purified by recrystallisation, or by rubbing with water to a thick cream, and washing with  $\text{H}_2\text{O}$  until  $\text{KCl}$  is removed (v. Lunge, *D. P. J.* 189, 488; Hunt, *B. 5*, 229). White, pearly, monoclinic plates. S.G. 2.35 (Kremers, *P.* 97, 1; 99, 25). S. ( $0^\circ$ ) 3.3; ( $15^\circ$ ) 6; ( $35^\circ$ ) 12; ( $50^\circ$ ) 19; ( $75^\circ$ ) 36; ( $104^\circ$ ) = B.P. 60. S. ( $120^\circ$ ) 73.7; ( $136^\circ$ ) 98.9; ( $160^\circ$ ) 148; ( $190^\circ$ ) 183 (Tilden a. Shenstone, *T.* 175, 23). S.G. of  $\text{KClO}_3$  Aq at  $19.5^\circ$  (Kremers, *P.* 96, 62; Gorlach, *Fr. 8*, 290) 1 p.c.  $\text{KClO}_3$  = 1.007; 2 p.c. 1.014; 3 p.c. 1.02; 4 p.c. 1.026; 5 p.c. 1.033; 6 p.c. 1.039; 7 p.c. 1.045; 8 p.c. 1.052; 9 p.c. 1.059; 10 p.c. 1.066. S. (alcohol) as follows: Gerardin *A. Ch.* [4] 5, 129).

M.P. about  $359^\circ$  (Carnelley, *C. J.* [2] 18, 277). Heated to about  $400^\circ$  evolution of  $\text{O}$  begins; if the temperature is not increased, evolution of  $\text{O}$  ceases when  $\text{KCl}$  and  $\text{KClO}_3$  are formed (v. Perchloric acid; Preparation, p. 20); if the temperature is increased the whole of the  $\text{O}$  is removed and  $\text{KCl}$  remains; when the temperature is lower than that at which  $\text{KClO}_3$  is decomposed the reaction approximates to that represented by the equation  $8\text{KClO}_3 = 5\text{KClO}_4 + 3\text{KCl} + 2\text{O}_2$  (Teed, *C. J.* 51, 283; Frankland a. Dingwall, *C. J.* 51, 274). If  $\frac{1}{2}$  pt. ppt.  $\text{MnO}_2$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{CuO}$ , or spongy  $\text{Pt}$ , is mixed with  $\text{KClO}_3$ ,  $\text{O}$  is evolved at a much lower temperature; about  $110^\circ$ – $120^\circ$  with  $\text{Fe}_2\text{O}_3$ ,  $200^\circ$ – $205^\circ$  with  $\text{MnO}_2$ ,  $230^\circ$ – $235^\circ$  with  $\text{CuO}$ ,  $260^\circ$ – $270^\circ$  with  $\text{Pt}$  black. The more finely divided the  $\text{CuO}$  the lower is the temperature at which evolution of  $\text{O}$  begins; the temperature is lowered by so little as  $\frac{1}{100}$ th part of very finely divided  $\text{CuO}$ ,  $\text{MnO}_2$ , or  $\text{Fe}_2\text{O}_3$ , but the greater the quantity of the foreign body the more rapid is the evolution of  $\text{O}$  (Mitscherlich, *P.* 55, 220; Wiederhold, *P.* 116, 171; 118, 186; Baudrimont, *J. Ph.* [4] 14, 81 a. 161).  $\text{KClO}_3$  is an energetic oxidiser; mixed with easily oxidised bodies, e.g.  $\text{S}$ ,  $\text{P}$ ,  $\text{Sb}_2\text{S}_3$ , and heated or rubbed, or sometimes even exposed to direct sunlight, explosions occur. Charcoal,  $\text{S}$ ,  $\text{Sb}$ ,  $\text{Sb}_2\text{S}_3$ , finely divided  $\text{Fe}$ ,  $\text{As}$ , very fine  $\text{Cu}$ , &c. dropped on to molten  $\text{KClO}_3$ , burn with production of much light (Böttger, *A. 57*, 138). Conc.  $\text{KClO}_3$  Aq boiled with  $\text{P}$  produces  $\text{KClAq}$ ,  $\text{K}_2\text{HPO}_4$  Aq, and  $\text{K}_2\text{HPO}_4$  Aq; with  $\text{As}$ ,  $\text{KClAq}$  and  $\text{K}_2\text{HASO}_4$  Aq are formed (Slatyer, *J. pr.* 60, 247). For the action of acids on  $\text{KClO}_3$ , v. CHLORINE, OXIDES OF; CHLORINE PEROXIDE, and CHLORINE TRIOXIDE.

**Rubidium chlorate.**  $\text{RbClO}_3$ . By decomposing  $\text{Rb}_2\text{SO}_4$  Aq by  $\text{Ba}(\text{ClO}_3)_2$  Aq. Small trimetric crystals. S. ( $4.7^\circ$ ) 2.8; ( $13^\circ$ ) 3.9; ( $18.2^\circ$ ) 4.9; ( $19^\circ$ ) 5.1 (Reissig, *A.* 127, 33).

**Silver chlorate.**  $\text{AgClO}_3$ . A slow stream of  $\text{Cl}$  is passed into  $\text{H}_2\text{O}$  containing  $\text{Ag}_2\text{O}$  or  $\text{Ag}_2\text{CO}_3$  in suspension; liquid is decanted from  $\text{AgCl}$  and is again treated with  $\text{Cl}$ ; after standing for some time at  $60^\circ$ , to convert any  $\text{AgClO}$  into  $\text{AgClO}_3$ , liquid is evaporated at  $100^\circ$  (Stas, *Chem. Propert.* 90). White, opaque, non-deliquescent, trimetric, crystals. S.G. 4.93 (Schneider, *P.* 106, 226; 107, 118). S. (about  $15^\circ$ ) 10; (about  $80^\circ$ – $100^\circ$ ) 50; insoluble in alcohol. Decomposed by  $\text{Cl}$  to  $\text{AgCl}$  while  $\text{HClO}$  remains in solution; gives  $\text{AgCl}$  and  $\text{O}$  on heating; mixed with  $\text{S}$  explodes more easily than  $\text{KClO}_3$ . A double salt  $\text{KClO}_3 \cdot \text{AgClO}_3$  is formed by heating equivalent quantities of  $\text{KClO}_3$  Aq and  $\text{AgClO}_3$  to  $200^\circ$  in a closed tube (Pfaundler, *C. C.* 1862, 349).

**Sodium chlorate.** By action of  $\text{Cl}$  on warm  $\text{NaOH}$  Aq; better by  $\text{KClO}_3$  Aq +  $\text{Na}_2\text{SiF}_6$  Aq.

S.G. of alcohol at $15^\circ$	S.G. 9793	S.G. 9873	S.G. 9939	S.G. 9967	S.G. 9999

S. (0°) 82; (40°) 128.5; (100°) 204 (Kremers, P. 97, 1; 99, 25). S. (alcohol, 83 p.c. 15°) S. Resembles  $\text{KClO}_3$ .

**Strontium chlorate.**  $\text{Sr}(\text{ClO}_3)_2 \cdot 8\text{H}_2\text{O}$ . Prepared as  $\text{Ba}(\text{ClO}_3)_2$ . Deliquescent needles; soluble in alcohol (Souhay, A. 102, 381).

**Zinc chlorate.**  $\text{Zn}(\text{ClO}_3)_2$ . By dissolving  $\text{ZnSO}_4$  in  $\text{HClO}_3\text{Aq}$ , or decomposing  $\text{ZnSiF}_6$  by  $\text{KClO}_3\text{Aq}$  (Henry, J. Ph. 25, 265).

**Thallium chlorate.** By adding  $\text{TlNO}_3\text{Aq}$  to  $\text{KClO}_3\text{Aq}$ ; the solution is decomposed by heat and on evaporation  $\text{TCIO}_3$  separates out (Crookes, C. N. 8, 195). A chlorate of ytterbium was obtained by Popp (A. 181, 179).

IV. PERCHLORIC ACID AND PERCHLORATES.  $\text{HClO}_4$ ;  $\text{MClO}_4$ . Mol. w. unknown for either the acid or its salts.

Stadion (G. A. 52, 197 a, 339) prepared potassium perchlorate by the action of  $\text{H}_2\text{SO}_4\text{Aq}$  on  $\text{KClO}_3$ ; he obtained the acid by decomposing the new salt by  $\text{H}_2\text{SO}_4\text{Aq}$ . Serullas (A. Ch. [2] 45, 270; 46, 294 a, 323), prepared the same perchlorate by heating  $\text{KClO}_3$  until the melted mass became semi-solid. The acid has been investigated by Roscoe (A. 121, 346).

**Formation.**—1. By heating  $\text{HClO}_3\text{Aq}$ , O and Cl being also evolved (Serullas, l.c.).—2. By the electrolysis of  $\text{ClAq}$  or  $\text{HClAq}$  (Riche, C. R. 46, 348).—3. By electrolysis of  $\text{KClO}_3\text{Aq}$ , with Pt electrodes, ozone is evolved and  $\text{KClO}_4$  and traces of  $\text{KCl}$  are formed (Lidoff a. Tichomiroff J. R. 1882, 341).—4. By adding ozone to  $\text{HClO}_3\text{Aq}$  Fairly (B. A. 1874, 58).

**Preparation.**—1.  $\text{KClO}_3$  is prepared by fusing  $\text{KClO}_3$  until the liquid mass becomes pasty;  $2\text{KClO}_3 = \text{KClO}_4 + \text{KCl} + \text{O}_2$ . Marignac (B. J. 24, 192) says that when  $6\frac{1}{2}$  litres O are evolved from 100 grams of  $\text{KClO}_3$ , the residue contains 65–66 p.c.  $\text{KClO}_4$ . The fused mass is repeatedly digested at 100° with conc.  $\text{HClAq}$ , to decompose  $\text{KClO}_3$ ; the residue is dissolved in the smallest quantity of boiling  $\text{H}_2\text{O}$ ; the crystals which separate on cooling are again digested with  $\text{HClAq}$  at 100°, and crystallisation is repeated from boiling water. Pure  $\text{KClO}_4$  gives no yellow colour on digestion with conc.  $\text{HClAq}$ . One part  $\text{KClO}_4$  is distilled with 4 parts very conc. pure  $\text{H}_2\text{SO}_4$ , so long as the distillate solidifies in the receiver; the crystalline distillate is melted, poured into a small retort, and gradually heated to 110° when yellowish fumes come off and a brownish-yellow distillate is formed. This distillate is redistilled very slowly and cautiously, heating being stopped whenever crystals begin to form in the neck of the retort. The distillate is preserved in small sealed glass bulbs.—2. 606 grams  $\text{KClO}_3$  are boiled with the  $\text{H}_2\text{SiF}_6\text{Aq}$  prepared from 1000 grams  $\text{CaF}_2$ ; after cooling, the  $\text{K}_2\text{SiF}_6$  is filtered off; the solution of  $\text{HClO}_3\text{Aq}$  is heated until white fumes of  $\text{HClO}_3$  appear; the liquid is then slowly distilled from a retort; the distillate is freed from  $\text{HClAq}$  and  $\text{H}_2\text{SO}_4\text{Aq}$  by shaking with  $\text{AgClO}_3$  and  $\text{Ba}(\text{ClO}_3)_2$ , filtered, and again distilled. From this  $\text{HClO}_3\text{Aq}$ , the pure acid may be obtained by distilling with 4 volumes conc.  $\text{H}_2\text{SO}_4$ , and rectifying as described in 1 (Roscoe, A. 121, 346).

The first product of the action of  $\text{H}_2\text{SO}_4$  on  $\text{KClO}_3$  is nearly pure  $\text{HClO}_4$ ; this is succeeded by a liquid containing 72.4 p.c.  $\text{HClO}_4$ , when this drops into the receiver crystals of  $\text{HClO}_4 \cdot \text{H}_2\text{O}$

are formed. When these crystals are slowly heated  $\text{HClO}_4$  distils over, but after a time the liquid containing 72.4 p.c.  $\text{HClO}_4$  is formed in the retort, and coming into contact with the  $\text{HClO}_4$  forms crystals of  $\text{HClO}_4 \cdot \text{H}_2\text{O}$ .

**Properties.**— $\text{HClO}_4$  is a colourless, oily, volatile, liquid; S.G. 1.782 at 15°. Fumes strongly in moist air. Very easily undergoes decomposition with explosion; even when kept in glass bulbs in the dark. Cannot be distilled without decomposition; at 75° change begins; at 92° white clouds come off, and a yellow gas smelling like  $\text{ClO}_2$ , also a few drops of a liquid resembling Br; at a higher temperature violent explosion occurs; the residue solidifies to white crystals with 87.76 p.c.  $\text{HClO}_4$  (Roscoe).  $\text{HClO}_4$  is an extremely powerful oxidiser; one drop on charcoal, paper, wood, &c., produces combustion with violent explosions. A drop falling on to the skin produces a severe wound. When the hydrate  $\text{HClO}_4 \cdot \text{H}_2\text{O}$  (*v. Combinations*, No. 1) is distilled under ordinary pressure nearly pure  $\text{HClO}_4$  passes over at 110°. The temperature then rises until 203° is reached, when it becomes constant, and a heavy oily liquid, exactly resembling conc.  $\text{H}_2\text{SO}_4$ , distils over; the same liquid is obtained by distilling  $\text{HClO}_3\text{Aq}$  until 203° is reached. This liquid contains 72.1 p.c.  $\text{HClO}_4$ , and does not correspond to a definite hydrate ( $\text{HClO}_4 \cdot 2\text{H}_2\text{O} = 73.6$ ,  $\text{HClO}_4 \cdot 3\text{H}_2\text{O} = 65.05$ , p.c.  $\text{H}_2\text{O}$ ) (Roscoe, l.c.; *v. also* Weppen, A. 29, 318).

**Reactions and Combinations.**—1.  $\text{HClO}_4$  combines with water with a hissing sound and production of much heat; Berthelot gives  $[\text{HClO}_4\text{Aq}] = 20,300$  (A. Ch. [5] 27, 214). If water is added little by little, crystals of the hydrate  $\text{HClO}_4 \cdot \text{H}_2\text{O}$  are obtained; these melt at about 50°; S.G. (liquid) 1.81 at 60°; decomposition into  $\text{HClO}_3$  and  $\text{HClO}_4 \cdot 2\text{H}_2\text{O}$  begins at 110°.—2.  $\text{HClO}_4\text{Aq}$  is not reduced by  $\text{H}_2\text{S}$ ,  $\text{SO}_2$ , or  $\text{HNO}_3\text{Aq}$ , nor by any known substance according to Berthelot (Z. [2] 38, 1).—3.  $\text{HClO}_4\text{Aq}$  dissolves Zn and Fe with evolution of H.

**Perchlorates.**— $\text{HClO}_4$  is a monobasic acid forming one series of salts,  $\text{MClO}_4$  or  $\text{M}(\text{ClO}_4)_2$ ; a few basic salts are also known, e.g.  $\text{BiOClO}_4$ . These salts are prepared by the action of  $\text{HClO}_4\text{Aq}$  on metals, oxides, or carbonates; or by the decomposition of  $\text{Ba}(\text{ClO}_3)_2\text{Aq}$  by sulphates; or by the decomposition of chlorates by heat (*v. Potassium chlorate*), or by  $\text{H}_2\text{SO}_4\text{Aq}$ , or by  $\text{HNO}_3\text{Aq}$  (Penny, A. 37, 203). The perchlorates are generally easily soluble in water;  $\text{KClO}_4$  is one of the least soluble of the salts. They are isomorphous with the permanganates. They are decomposed by heat into chlorides and O, or into oxides, Cl, and O, but at higher temperatures than chlorates. When  $\text{KClO}_4$  is heated so as to evolve only a part of its O, some  $\text{KClO}_3$  is formed (Frankland a. Dingwall, C. J. 51, 278; Teed, C. J. 51, 283). Conc.  $\text{H}_2\text{SO}_4$  forms  $\text{HClO}_4$  at 100°; conc.  $\text{HClAq}$  does not act on perchlorates at 100°. Solutions of perchlorates are very slowly, if at all, reduced by reagents which readily reduce chlorates.

The following perchlorates have been prepared:  $\text{NH}_4\text{ClO}_4$  (Roscoe), isomorphous with  $\text{KClO}_4$ ;  $\text{Ba}(\text{ClO}_4)_2$  (Groth, P. 133, 226; Potilitzin, C. C. 1887, 1218);  $\text{Cd}(\text{ClO}_4)_2$ , very deliquescent (Serullas, A. Ch. [2] 45, 270; 46, 294 a, 323);

$\text{Ca}(\text{ClO}_2)_2$ , very deliquescent (Serullas, *l.c.*);  $\text{Cu}(\text{ClO}_2)_2$ , large, blue, deliquescent crystals (Serullas, Roscoe);  $\text{Fe}(\text{ClO}_2)_2$ , long colourless needles, stable in air (Serullas);  $\text{Fe}(\text{ClO}_2)_2 \cdot 3\text{H}_2\text{O}$ , greenish, very deliquescent, crystals (Roscoe);  $\text{Mn}(\text{ClO}_2)_2$ , deliquescent, not obtained in crystals (Serullas);  $\text{HgClO}_2$ , non-deliquescent needles (Serullas);  $\text{Hg}(\text{ClO}_2)_2 \cdot \frac{1}{2}\text{H}_2\text{O}$ , very deliquescent (Roscoe);  $\text{Hg}(\text{ClO}_2)_2$  (Serullas);  $\text{KClO}_2$  (v.  $\text{HClO}_2$ , Preparation);  $\text{S}$ , (15°) 1.6, nearly insoluble in alcohol;  $\text{AgClO}_2$  (Serullas);  $\text{NaClO}_2$  (Penny, *A.* 37, 203);  $\text{TiClO}_2$  decomposes in moist air (Crookes, *C. N.* 8, 195);  $\text{Zn}(\text{ClO}_2)_2$ , deliquescent needles. M. M. P. M.

**CHLORINE, SULPHIDE OF**, better called Sulphur chloride; v. SULPHUR.

**CHLORITES** — Salts of Chlorous acid, v. CHLORINE, OXY-ACIDS OF, p. 18.

**CHLORO-** Use of this prefix applied to inorganic compounds; for Chloro-compounds and Chloro-salts v. the element the chloro-compound of which is sought for, or the salts to the names of which Chloro- is prefixed. Thus Chlorophosphide of nitrogen will be found under Nitrogen, and Chloro-platinate of potassium under PLATINATES.

**CHLORO-ACETAL** v. CHLORO-ACETIC ALDEHYDE and CHLORAL.

**CHLORO-ACETAMIDE** v. CHLORO-ACETIC ACID, and ACETO-CHLORO-AMIDE, vol. i. p. 5.

**CHLORO-ACETAMIDO-** v. CHLORO-AMIDO-

**CHLORO-ACETANILIDE** v. CHLORO-ANILINE.

**CHLORO-acetanilide** v. ANILINE, vol. i. p. 274.

**CHLORO-ACETENE**. Is merely a mixture of aldehyde, paraldehyde, and  $\text{COCl}_2$  (Kekulé a. Zincke, *A.* 162, 141; cf. Harnitzky, *A.* 111, 192).

**CHLORO-ACETIC ACID**  $\text{C}_2\text{H}_3\text{ClO}_2$ , i.e.  $\text{CH}_2\text{Cl} \cdot \text{CO}_2\text{H}$ . Mol. w. 94.5. [63°]. An unstable modification [52°] (Tollens, *B.* 17, 664). (186°). S.G. 1.366.

**Formation.**—1. From ethylene and chlorine peroxide (Füst, *B.* 11, 2188; *A.* 206, 78).—2. Together with  $\text{AcCl}$  by the action of chlorine on acetic anhydride (Gal, *A.* 122, 378).—3. By passing chlorine into acetyl chloride mixed with iodine and decomposing the product with water (Jazukowitsch, *Z.* 1868, 234).—4. Chloro-acetyl chloride is formed, together with di-chloro-acetyl chloride, by boiling  $\text{AcCl}$  (40g.) with  $\text{PCl}_5$  (200g.) for some weeks (Michael, *J. pr.* [2] 35, 95).

**Preparation.**—1. Dry chlorine is passed into a retort containing acetic anhydride heated to 100°, dry acetic acid being simultaneously run in. The acetyl chloride which is formed:

$(\text{CH}_3\text{CO})_2\text{O} + \text{Cl}_2 = \text{CH}_3\text{Cl} \cdot \text{CO}_2\text{H} + \text{CH}_3\text{COCl}$  is at once recovered by the acetic acid into anhydride, which is again attacked by the chlorine, and so on, so that a small quantity of anhydride suffices for the chlorination of a large quantity of acetic acid. When the absorption of the chlorine slackens the mixture is fractionally distilled (Hentschel, *B.* 17, 1286; cf. R. Hoffmann, *A.* 102, 1).—2. By passing chlorine through a heated mixture of 50 g. iodine and 500 c.c. nearly glacial acetic acid S.G. 1.065. The rectified product contains a little iodo-acetic acid (Huge Müller, *C. J.* 17, 398).

**Properties.**—Deliquescent trimetric tablets or needles. Blisters the skin; nearly inodorous. V. sol. water, with absorption of heat.

**Reactions.**—1. Water slowly converts it on

heating into glycollic acid (Buchanan, *B.* 4, 840, 853). Caustic potash acts similarly, while baryta forms di-glycollic acid  $\text{C}_2\text{H}_4\text{O}_3$  (Kekulé, *A.* 105, 288; cf. Schwab, *R. T. C.* 2, 46).—2. Chloro-acetic acid (10 g.) boiled with  $\text{PCl}_5$  (88 g.) yields tetra-chloro-ethylene and other bodies (Michael, *Am.* 9, 216).—3. Sodium-amalgam partially reduces it to acetic acid.—4. By heating with dimethylaniline it is broken up into methyl chloride and  $\text{CO}_2$ ; this decomposition is produced by the intermediate formation of the body  $\text{PhMe} \cdot \text{ClN} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ , which splits up into  $\text{CO}_2$ ,  $\text{CH}_3\text{Cl}$ , and dimethylaniline (Silberstein, *B.* 17, 2661).

**Salts.**— $\text{KA}'$  1.14g: laminae, v. sol. water but not deliquescent and not dehydrated at 100°, but converted into glycollic acid at a higher temperature. The same change takes place when its aqueous solution is evaporated even below 100°.— $\text{KHA}'$ : small pearly crystals, sl. sol. water.— $\text{BaA}'$ : prisms. Decomposed but slightly when its aqueous solution is evaporated, and separates almost completely on cooling a hot saturated solution.— $\text{AgA}'$ : pearly scales; detonates at 140°–120°.

**Methyl chloro-acetate**  $\text{CH}_3\text{Cl} \cdot \text{CO}_2\text{Me}$  (130°) (Schreiner, *A.* 197, 1). V.D. 3.71 (for 3.74). S.G. 1.22; 1.235 (Henry, *C. R.* 101, 250). S.H. 389 (R. Schiff, *G.* 17, 286). Prepared by passing  $\text{HCl}$  into a solution of chloro-acetic acid in  $\text{MeOH}$  (Henry, *B.* 6, 743) or from  $\text{CH}_3\text{Cl} \cdot \text{CO}_2\text{Cl}$  and  $\text{MeOH}$  (P. J. Meyer, *B.* 8, 1152). Insol. water. Converted by ammonia into chloro-acetamide.

**Chloro-methyl ether**  $\text{CH}_3\text{Cl} \cdot \text{CO}_2 \cdot \text{CH}_2\text{Cl}$  (197°). S.G. 1.322. From  $\text{CH}_3\text{Cl} \cdot \text{CO}_2\text{Cl}$  and glycolic chlorhydrin (Henry, *C. R.* 97, 1308).

**Ethyl ether**  $\text{CH}_3\text{Cl} \cdot \text{CO}_2 \cdot \text{Et}$ . Mol. w. 122. V.D. 4.24 (calc. 4.23). (143°) (Schreiner, *A.* 197, 1); (144.5°) (Schiff, *A.* 220, 108). S.G. 1.1585 (Brühl, *A.* 203, 21). S.H. 401.  $\mu$  1.428.  $R_D$  43.51. S.V. 123.1.

Formed by mixing chloro-acetyl chloride with alcohol in the cold (Willm, *A. Ch.* [3] 49, 97; *A.* 102, 109); or by heating chloro-acetic acid (200 g.) with alcohol (120 g.) and  $\text{H}_2\text{SO}_4$  (25 g.) for 6 hours at 100° (Conrad, *A.* 188, 218). Oil with ethereal odour. With ammonia it forms chloro-acetamide. It unites with  $\text{Me}_2\text{S}$  at 100° forming the hydrochloride of di-methyl-thetine (Crum Brown a. Letts, *Pr. E.* 28, 583).

Chloro-acetic ether (2 mols.) heated with (1, 3, 4) tolylene-diamine (3 mols.) at 100° forms oxy-toluquinaxaline dihydride thus:

When, however, chloro-acetic ether (2 mols.) is heated with a smaller quantity (1 mol.) of tolylene-diamine at 100° a compound  $\text{C}_{12}\text{H}_{12}\text{N}_2\text{O}_2$  [147°] is formed; it may be  $\text{C}_6\text{H}_4\text{Me} \cdot \begin{array}{c} \text{NH} \cdot \text{CH} \\ \text{N}(\text{CH}_2 \cdot \text{CO}_2\text{Et}) \end{array} \cdot \text{CO}$  (Hinsberg, *A.* 237, 561).

**Chloro-ethyl ether**  $\text{CH}_3\text{Cl} \cdot \text{CO}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{Cl}$  (198° uncor.). S.G. 1.322. From chloro-acetyl chloride and glycolic chlorhydrin (Henry, *C. R.* 97, 1308). Also from ethylene and  $\text{Cl}_2\text{O}$  (Mulder a. Penn, *B.* 11, 1958).

**Propyl ether**  $\text{CH}_3\text{Cl} \cdot \text{CO}_2 \cdot \text{Pr}$ . (161°) (Schrei-

ner, A. 197, 1). S.G.  $\pm$  1.11 (Henry, J. pr. [2] 81, 127). S.H. 422 (Schiff, G. 17, 486).

*n*-Butyl ether  $\text{CH}_3\text{Cl.CO.C}_4\text{H}_9$ . (175°). S.G.  $\pm$  1.103;  $\pm$  1.081. V.D. 5.1 (Gehring, Bl. [2] 46, 146; C. R. 102, 1899).

Isoamyl ether  $\text{CH}_3\text{Cl.CO.C}_5\text{H}_{11}$ . (190°). S.G.  $\pm$  1.063 (Hugoumenq, Bl. [2] 45, 328).

*sec* Octyl ether  $\text{CH}_3\text{Cl.CO.C}_8\text{H}_{17}$ . (234°). S.G.  $\pm$  0.990. From octyl alcohol of castor oil (Gehring, C. R. 104, 1000).

Phenyl ether  $\text{CH}_3\text{Cl.CO.C}_6\text{H}_5$ . (40°). (230°-235°). From phenol and chloro-acetyl chloride. Needles (Prevost, J. pr. [2] 4, 379).

Benzyl ether  $\text{CH}_3\text{Cl.CO.C}_6\text{H}_5$ . (148°) at 9 mm. S.G.  $\pm$  1.222.

Chloride v. CHLORO-ACETYL CHLORIDE.

Amide  $\text{CH}_3\text{Cl.CO.NH}_2$ . Chloro-acetamide.

[119°] (Menschutkin a. Jermolajeff, Z. [2] 7, 5); [116°] (Bauer, A. 229, 165). (225°). S. 10 at 24°.

S. (alcohol) 9.5 at 24°. From chloro-acetic ether and aqueous or gaseous  $\text{NH}_3$ , br from chloro-acetyl chloride and dry ammonia (Willm. A. Ch. [3] 49, 99). Thick monoclinic prisms or flat plates (from alcohol). Its aqueous solution after treatment with  $\text{H}_2\text{O}$  deposits slender needles of  $\text{Hg}(\text{NH}_4\text{CO}_2\text{CH}_2\text{Cl})_2$ . Alcoholic KCy forms  $\text{C}_2\text{H}_5\text{Cl.N}_2\text{O}$  (?) (Schiff a. Speciale, G. 9, 885). Br and KOH aq give chloro-methyl-chloro-acetyl-urea  $\text{CH}_3\text{Cl.NH.CO.NH.CO.CH}_2\text{Cl}$  (Wallach, A. 184, 30).

Anilide  $\text{CH}_3\text{Cl.CO.NHPh}$ . (184°). From aniline and ethereal  $\text{CH}_3\text{Cl.COCl}$  (Wallach a. Kamensky, A. 214, 221; Tommasi, Bl. 19, 400; Cech, B. 10, 1376; Meyer, B. 8, 1152). Crystallises from benzene. When treated with  $\text{PCl}_5$ , it gives off  $\text{HCl}$  and forms a base whose hydrochloride is insol. water, benzene or ether, but crystallises from alcohol in long yellow silky needles which appear to be  $\text{C}_6\text{H}_5\text{Cl.N.HCl}$ .

*p*-Toluide  $\text{CH}_3\text{Cl.CO.NHC}_6\text{H}_4\text{Me}$ . [162°] (Meyer; Tommasi, C. J. 26, 911; 27, 628).

Nitrile  $\text{CH}_3\text{Cl.CN}$ . (124°). S.G.  $\pm$  1.193. V.D. 2.62. From the amide and  $\text{P}_2\text{O}_5$ . The yield is 50 p.c. of the theoretical (Bisschopineck, B. 6, 732; Engler, B. 6, 1003; Bauer, A. 229, 165).

Di-chloro-acetic acid  $\text{C}_2\text{HCl}_2\text{O}_2$  i.e.  $\text{CHCl}_2\text{CO}_2\text{H}$ . (190°). S.G.  $\pm$  1.522.

Formation.—1. By the chlorination of acetic or of chloro-acetic acid (Mauenné, Bl. [2] 1, 417). 2. By the action of aqueous KCy upon chloral (Wallach, A. 173, 295).

Preparation.—By boiling chloral hydrate (50 g.) with water (250 g.) and  $\text{K}_2\text{FeCy}_4$  (84 g.); the resulting potassium salt being extracted by alcohol (Wallach, B. 9, 1212; 10, 1526).

Properties.—Corrosive liquid; solidifies below 0°.

Reactions.—1. Converted into glyoxylic acid by heating with moist  $\text{Ag}_2\text{O}$ . The same reaction is slowly effected by water at 100°, and by alkalis (Beckurts a. Otto, B. 14, 583).

Salts.—KA': laminae (from alcohol).—AgA': prisms, sl. sol. cold water; decomposes violently at 80°.—CaA': 3 aq; needles (from alcohol).—Na(UrO)<sub>2</sub>A' (Clarke a. Owens, B. 14, 35).

*p*-Toluidine di-chloro-acetate  $\text{C}_6\text{H}_4\text{Me.NH}_2\text{O.CO.CHCl}_2$ : [136°]; white needles (Duisberg, B. 18, 194).

Methyl ether  $\text{CH}_3\text{Cl.CO.Me}$ . (141°) (Wallach, A. 173, 299). S.G.  $\pm$  1.380 (Henry, C. R. 101, 250). S.H. 322 (Schiff, G. 17, 286).

Ethyl ether  $\text{CH}_3\text{Cl.CO.Et}$ . (157°). S.G.  $\pm$  1.2821 (Brühl, A. 203, 22).  $\rho_d$  1.444.  $\rho_{20}$  52.19. V.D. 5.38 (for 5.42). S.H. 388 (S.). S.V. 143.4.

Formation.—1. Together with glyoxylic ether by heating  $\text{C}_2\text{Cl}_4$  with  $\text{NaOEt}$  at 100°-150° for 13 hours.—2. By adding chloral hydrate (1 mol.) to potassium cyanide (1 mol.) in absolute alcohol:  $\text{CCl}_4, \text{CH}_3\text{OH}$ , +  $\text{EtOH} + \text{KCN}$

=  $\text{CHCl}_2\text{CO}_2\text{Et} + \text{HCN} + \text{KCl} + \text{H}_2\text{O}$ . Or by gently heating chloral cyanhydrin (1 mol.) with alcoholic  $\text{NaOEt}$  (Wallach, A. B. 6, 114; 10, 1527, 2120).

Reactions.—1. Boiling alcoholic KCy gives acetic and oxalic acids (Claus, B. 11, 496, 1044).—2. Silver, or Na, converts it into maleic ether. 3. Alcoholic KOH gives glycollic acid (Claus, B. 14, 1066).

Propyl ether  $\text{CH}_3\text{Cl.CO.Pr}$ . S.H. 352.

Isobutyl ether  $\text{CH}_3\text{Cl.CO.C}_4\text{H}_9$ . (183°).

*sec* Octyl ether  $\text{CH}_3\text{Cl.CO.C}_8\text{H}_{17}$ . (244°) (Gehring, C. R. 104, 1000).

Benzyl ether  $\text{CH}_3\text{Cl.CO.C}_6\text{H}_5$ . (179°) at 60 mm. S.G.  $\pm$  1.313 (Seubert, B. 21, 281).

Amide  $\text{CH}_3\text{Cl.CONH}_2$ . [98°] (Hantzsch a. Zeckendorff, B. 20, 1309). (234°).

From the ether and alcoholic  $\text{NH}_3$ , or from chloral cyanhydrin  $\text{CCl}_3\text{CH(OH).CN}$  and aqueous  $\text{NH}_3$  (Pinner a. Fuchs, B. 10, 1066). Monoclinic columns. V. sol. hot water. It unites with chloral forming  $\text{CCl}_3\text{CH(OH).NH.CO.CHCl}_2$ , which crystallises from water in prisms.  $\text{PCl}_5$  converts it into  $\text{CHCl}_2\text{CCl:N.POCl}_2$  (Wallach, A. 184, 28).

Ethylamide  $\text{CH}_3\text{Cl.CONH.C}_2\text{H}_5$ . (226°). Converted by  $\text{PCl}_5$  into  $\text{CHCl}_2\text{CCl:N.POCl}_2$  (140°-150°) and  $\text{CHCl}_2\text{CCl:N.Et}$  (c. 163°).

Anilide  $\text{CH}_3\text{Cl.CO.NHPh}$ . [118°]. Formation.—1. By the action of aniline on chloral in presence of KCy or on chloral cyanhydrin (Cech, B. 9, 337; 10, 1265).—2. From aniline, di-chloro-acetic acid, and  $\text{P}_2\text{O}_5$  (C.).—3. By warming di-chloro-acetamide with aniline (C.). Properties.

Crystalline scales (from water); sl. sol. hot water; sol. KOH aq and reppd. by acids. Nitrile  $\text{CH}_3\text{Cl.CN}$ . (113°). V.D. 3.82. S.G.  $\pm$  1.374 (Bisschopineck, B. 6, 732). Formed by distilling the amide with  $\text{P}_2\text{O}_5$ . Absorbs  $\text{HCl}$  forming a crystalline compound which, when heated in a sealed tube at 140°, splits up into  $\text{HCl}$  and a polymeride of dichloro-acetonitrile [70°] (Weddigs a. Körner, J. pr. [2] 31, 176).

Di-chloro-ortho-acetic ether  $\text{CHCl}_2\text{C(OEt)}_2$ . (205°). Formed together with other bodies by heating  $\text{C}_2\text{Cl}_4$  with  $\text{NaOEt}$  at 100°-120°. Decomposed by water. Decomposed by  $\text{NaOEt}$  into  $\text{NaCl}$  and di-ethyl-glyoxylic ether (Geuther a. Brockhoff, J. pr. [2] 7, 101).

Tri-chloro-acetic acid  $\text{C}_2\text{HCl}_3\text{O}_2$  i.e.  $\text{CCl}_3\text{CO}_2\text{H}$ . Mol. w. 163. [55°]. [195°]. S.G.  $\pm$  1.617. V.D. 5.3. Formation.—1. By the action of dry chlorine (3 mols.) on glacial acetic acid (1 mol.) in sunshine (Dumas, A. Ch. [2] 73, 75).—2. By the oxidation of chloral with  $\text{HCl}$  and  $\text{KClO}_3$ , and of chloral or metachloral with fuming  $\text{HNO}_3$  (Kolbe, A. 54, 182).—3. Together with  $\text{C}_2\text{Cl}_4$  by passing chlorine into  $\text{C}_2\text{Cl}_4$  under water in sunlight (K.). 4. From  $\text{CCl}_3\text{CO}_2\text{Cl}$ , which is formed by chlorinating ether (Malaguti, A. Ch. [3] 16, 10).

Preparation.—1. Chloral hydrate (155 pts.) is just melted and fuming  $\text{HNO}_3$  (63 pts.) is added. The reaction proceeds without application of heat, and after half an hour the liquid is fractionally distilled (De Clermont, A. Ch. [6] 6, 185;

[5] 2, 401; C. R. 78, 112, 501; 74, 942; 76, 774; 81, 1270; cf. Tommasi a. Meldola, C. J. 27, 314; Judson, Z. [2] 7, 40).—2. Chloral hydrate (165 g.) is mixed with  $\text{KClO}_3$  (37 g.); as soon as the mixture is melted a violent action sets in, with evolution of gas, and potassium tri-chloro-acetate (120 g.) is formed (Seubert, B. 16, 3336, 3339).

**Properties.**—1. Deliquescent, rhombohedral scales. V. sol. water. Blisters the skin. Its vapour is pungent. Markedly exhibits superfusion.

**Reactions.**—1. Conc.  $\text{H}_2\text{SO}_4$  forms  $\text{CO}$ ,  $\text{CO}_2$ , and  $\text{HCl}$ .—2. Both the acid and its salts are decomposed by boiling with water or alkalis into  $\text{CO}_2$  and chloroform. Ammonia, dimethyl-aniline, and  $\text{KCy}$  also liberate chloroform (Silberstein, B. 17, 2661; Bourgoin, Bl. 37, 403; C. R. 94, 448).—3. It is reduced to acetic acid by fuming  $\text{HI}$  at  $100^\circ$  (Clermont), by electrolysis ( $\text{K}$ ), or, in aqueous solution, by ( $\frac{1}{2}$  p.c.) potassium amalgam (Melsens, A. Ch. [3] 10, 233).—4.  $\text{NaOEt}$  forms sodium chloride, carbonate, and formate.—5.  $\text{K}_2\text{SO}_4$  aq. for  $\text{CHCl}(\text{SO}_3\text{K})\text{CO}_2\text{K}$  1 aq (Rathke, A. 161, 149).—6. Forms a compound with aluminum chloride, which is decomposed by steam thus:  $(\text{CCl}_3\text{CO})_2\text{Al}_2\text{Cl}_3 + 6\text{H}_2\text{O} = 2\text{CHCl}_3 + 2\text{CO}_2 + 4\text{HCl} + \text{Al}_2(\text{OH})_6$  (Elbs a. Tölle, J. pr. [2] 32, 624).

**Salts.**— $\text{KA}'$  aq.: long slender needles. Heated with bromine it forms  $\text{CO}_2$ ,  $\text{KBr}$ , and  $\text{CBrCl}_3$  (Van 't Hoff, B. 10, 678).— $\text{KHA}'_2$ : octahedra: S. 26.1 at  $0^\circ$ ; 33.75 at  $20^\circ$  (Seubert).— $\text{NaA}'$  3aq. On dry distillation it gives  $\text{NaCl}$ ,  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{COCl}_2$ , tri-chloro-acetyl chloride, tri-chloro-acetic acid and its anhydride, and a little  $\text{C}_2\text{Cl}_4$  (Henry, B. 12, 1844).— $\text{NH}_4\text{A}'$  2aq: [80°]: prisms. Boils at  $110^\circ$ – $115^\circ$ , giving off chloroform and ammonium bi-carbonate, and leaving  $\text{NH}_4\text{A}'$ , which is solid at  $160^\circ$ , but at a higher temperature splits up into  $\text{NH}_4\text{Cl}$ ,  $\text{CO}$ , and  $\text{COCl}_2$  (M.).— $\text{NH}_4\text{HA}'_2$ : octahedra.— $\text{LiA}'$  2aq: deliquescent prisms.— $\text{TlA}'$ — $\text{TiHA}'_2$ — $\text{AgA}'$ : laminæ, sl. sol. water; explodes when heated, forming  $\text{AgCl}$ ,  $\text{CO}$ ,  $\text{CO}_2$ , and tri-chloro-acetic anhydride.— $\text{CaA}'$  6aq: prismatic needles.— $\text{CaA}'_2$  3 aq.— $\text{SrA}'$  6aq: radiate groups of prisms.— $\text{BaA}'$  6aq: very thin laminæ.— $\text{MgA}'$  4aq.— $\text{ZnA}'$  6aq: laminæ.— $\text{CuA}'$  6aq (Judson, B. 3, 782).— $\text{HgA}'_2$ : prismatic needles.— $\text{Hg}_2\text{A}'_2$ : small needles, sl. sol. water.— $\text{PbA}'$  aq: large prisms, v. sol. water, sl. sol. alcohol.

**Methyl ether**  $\text{CCl}_3\text{CO}_2\text{Me}$  (154°) (Henry, C. R. 101, 250). S.G. 1.489. S.H. 277 (Schiff, G. 17, 286). Obtained by distilling the acid with methyl alcohol and  $\text{H}_2\text{SO}_4$ ; or by the action of methyl alcohol on the chloride or chlorinated aldehyde. Oil, smelling of peppermint.

**Tri-chloro-methyl ether**  $\text{CCl}_3\text{CO}_2\text{CCl}_3$ , S.G. 1.705. (c.  $200^\circ$ ). From the preceding or from methyl acetate by chlorine in sunshine. Said to be identical with the penta-chloro-ethyl ether of chloro-formic acid  $\text{Cl}_3\text{CO}_2\text{OCCl}_3$ , (180°–183°), S.G. 1.724 (Cahours, A. 64, 315). Decomposed by moist air and by aqueous alkalis into  $\text{HCl}$ ,  $\text{CO}_2$ , and tri-chloro-acetic acid. **Reactions.**—1. Ammonia gives tri-chloro-acetamide.—2. Alcohol gives tri-chloro-acetic ether and chloroformic ether; methyl alcohol acts similarly.—3. Its vapour passed through a red-hot tube gives  $\text{COCl}_2$  and tri-chloro-acetyl chloride.

**Ethyl ether**  $\text{CCl}_3\text{CO}_2\text{Et}$  (167°). S.G. 1.8226 (Brühl).  $\mu_D^{20}$  1.4567.  $n_D^{20}$  1.4567. S.H. 296.

V.D. 6.59 (for 6.61). S.V. 163.8 (Schiff). Obtained by distilling the acid with alcohol and a little  $\text{H}_2\text{SO}_4$  (Clermont, A. Ch. [6] 8, 241). Oil, smelling of peppermint. Heated with  $\text{KCy}$  and absolute alcohol it yields  $\text{CO}_2$  and chloroform (Claus, A. 191, 58).  $\text{PCl}_5$  at  $150^\circ$  forms  $\text{EtCl}$ ,  $\text{POCl}_3$ , and  $\text{CCl}_3\text{COCl}$  (Michael, Am. 9, 213). Heated with  $\text{NaOEt}$  (containing  $\text{NaOH}$ ) it forms orthoformic ether,  $\text{NaCl}$ , and  $\text{Na}_2\text{CO}_3$  (Klieh, J. 1876, 621). With  $\text{K}_2\text{SO}_4$  it forms  $\text{CHCl}(\text{SO}_3\text{K})\text{CO}_2\text{K}$  1 aq (Rathke, A. 161, 166).

**Penta-chloro-ethyl ether**  $\text{CCl}_3\text{CO}_2\text{CCl}_3$  (245°). S.G. 1.79 (Malaguti, A. Ch. [3] 16, 57; Cloez, A. Ch. [3] 17, 304). Formed by passing chlorine through acetic ether, finally in sunshine (Leblanc, A. Ch. [3] 10, 200). Liquid, gradually decomposed by moist air into  $\text{HCl}$  and tri-chloro-acetic acid. **Reactions.**—1. Alcohol forms tri-chloro-acetic ether.—2. Ammonia forms tri-chloro-acetamide. 3. Prolonged action of chlorine forms  $\text{C}_2\text{Cl}_6$ .—4. Passage through a tube at  $400^\circ$  yields tri-chloro-acetyl chloride.

**Propyl ether**  $\text{CCl}_3\text{CO}_2\text{Pr}$  (187°) (Clermont, C. R. 96, 437). S.H. 309.

**Isobutyl ether**  $\text{CCl}_3\text{CO}_2\text{CH}_2\text{Pr}$  (188°) (J.).

**Isoamyl ether**  $\text{CCl}_3\text{CO}_2\text{C}_4\text{H}_9$  (217°) (C.).

**s-Octyl ether**  $\text{CCl}_3\text{CO}_2\text{C}_7\text{H}_{15}$  (260°) (Gerhard, C. R. 104, 1001). Light oil.

**Benzyl ether**  $\text{CH}_2\text{PhA}'$  (179°) at  $50^\circ$  mm. S.G. 1.389.

**Anhydride**  $(\text{CCl}_3\text{CO})_2\text{O}$  (224°). Formed by treating the acid with  $\text{PCl}_5$  or  $\text{CCl}_3\text{COCl}$  (Buckney a. Thomsen, B. 10, 698; Clermont, Bl. [2] 30, 505; C. R. 86, 337). Hygroscopic liquid, rapidly converted into the acid by water.

**Chloride v. Tri-chloro-acetyl chloride.**

**Amide**  $\text{CCl}_3\text{CO}_2\text{NH}_2$ . Mol. w. 162. [186°].

(239°). Formed by the action of ammonia on tri-chloro-acetyl chloride, on tri-chloro-acetic ether, on perchlorinated acetic ether (v. supra), and on perchlorinated formic, carbonic, oxalic, and succinic ethers (Malaguti, A. 56, 286; Cloez, A. 60, 261, A. Ch. [3] 19, 352; Gerhard, Compt. Chim. 1848, 277). **Preparation.**—By mixing  $\text{NH}_3$  (1 pt.) dissolved in alcohol (10 pts.) with trichloroacetic ether (11 pts.) dissolved in alcohol (16 pts.). The mixture is kept cool. After 12 hours the reaction is complete (A. Weddige, J. pr. [2] 33, 78). **Properties.**—Monoclinic tables (from water); sweetish taste. Sl. sol. water, v. sol. alcohol and ether. **Reactions.**—1. Ammonia forms ammonium tri-chloro-acetate.—2.  $\text{P}_2\text{O}_5$  gives the nitrile.—3.  $\text{PCl}_5$  gives  $\text{CCl}_3\text{CO}_2\text{N.POCl}_3$  [c.  $81^\circ$ ] (c.  $257^\circ$ ) (Wallach, A. 184, 23).

**Chloro-amide**  $\text{CCl}_3\text{CO}_2\text{NHCl}$  [121°]. Formed by the action of chlorine-water on tri-chloroacetamide (Cloez, A. Ch. [3] 17, 305). Very volatile with steam. Large plates. Sol. alcohol, and ether, sl. sol. water. It dissolves in  $\text{NH}_3$  aq. with re-formation of tri-chloro-acetamide. It is scarcely altered by boiling with alcoholic  $\text{KOH}$ . By neutralising the alcoholic solution of the chloro-amide with alcoholic  $\text{KOH}$  a well crystallised potassium salt  $(\text{CCl}_3\text{CO}_2\text{NHCl})\text{K}$  is formed (Steiner, B. 16, 1606).

**Methylamide**  $\text{CCl}_3\text{CONHMe}$  [106°]. From tri-chloro-acetic ether and methylamine. Crystals, sl. sol. water and ether, slowly attacked by  $\text{HNO}_3$  (Franchimont a. Klobbie, R. T. C. 6, 284).

**Di-methyl-amide**  $\text{CCl}_3\text{CONMe}_2$  [c.  $12^\circ$ ].

(288°). S.G. 1.441. V.D. 6.68. Not attacked by  $\text{HNO}_3$  (S.G. 1.53) (F. a. K.).

**Ethyl-amide**  $\text{C}_2\text{H}_5\text{CONH}_2$ . [74°]. (230°). Quadrangular tables. Insol. cold water, v. sol. alcohol, ether, or chloroform (Wallach & Kamenisky, A. 214, 225).  $\text{PCl}_5$  appears to form the imido-chloride  $\text{CCl}_2\text{C(NEt)}_2$ , but this gives no basic condensation product.

**Di-ethyl-amide**  $\text{C}_2\text{H}_5\text{CONEt}_2$ . [27°] (F. a. K.); [90°] (Cloeze). V.D. 7.23 (F. a. K.). From hexa-chloro-acetone and  $\text{NEt}_3$  (Cloeze, jun., A. Ch. [6] 9, 145). Crystals. Not attacked by pure  $\text{HNO}_3$  (S.G. 1.53) (F. a. K.).

**Allyl-amide**  $\text{C}_3\text{H}_5\text{CONH}_2$ . [45°]. (190°). From allylamine and hexa-chloro-acetone (Cloeze).

**Anilide**  $\text{C}_6\text{H}_5\text{CONH}_2$ . [94°]. Scales (from alcohol); gives no basic condensation product with  $\text{PCl}_5$ .

**o-Toluide**  $\text{C}_6\text{H}_4(\text{CH}_3)\text{CONH}_2$ . [67°]. (215°). From hexa-chloro-acetone and o-toluidine (Cloeze, jun., A. Ch. [6] 9, 145).

**p-Toluide**  $\text{C}_6\text{H}_4(\text{CH}_3)\text{CONH}_2$ . [80°]. (185°) (Cloeze).

**Nitrile**  $\text{CCl}_3\text{CN}$ . (84°). S.G. 1.439. V.D. 5.08. Formed by the action of chlorine on acetonitrile containing iodine (Beckurts, B. 9, 1594). From the amide and  $\text{P}_2\text{O}_5$ ; the yield is 90 p.c. (Dumas, Malaguti, & Leblanc, C. R. 25, 442; Bisschopinck, B. 6, 732; Bauer, A. 229, 165). Pungent liquid, insol. water, sol. alcohol, ether, and light petroleum. Forms a crystalline compound with  $\text{HBr}$  which is decomposed by water. Warmed with  $\text{HCl}$  changes to trichloro-acetic acid. Polymerises when kept.  $\text{NaOEt}$  forms ethyl derivatives of the nitriles of dichloro-glycolic acid, and of chloro-glyoxylic acid.

**Paranitride**  $(\text{CCl}_3\text{CN})_2$ . **Per-chloro-trimethyl-cyanidine**. [96°]. **Formation**.—1. Cyanofornic ether,  $\text{CN.CO.Et}$ , is distilled with  $\text{PCl}_5$ , and the liquid product, probably  $\text{CN.COCl}$ , is heated in a sealed tube at 160° with  $\text{PCl}_5$ . The product is distilled with steam and crystallised from alcohol. The yield is 6 per cent. (A. Weddige, J. pr. [2] 28, 188; 33, 77).—2. From ordinary tri-chloro-acetonitrile by saturating it with  $\text{HCl}$  and exposing it, in sealed tubes, to sunlight. In about a year the contents of the tubes solidifies. The solid nitrile is crystallised from alcohol. **Properties**.—Large prisms (from hot alcohol). Sol. alcohol, benzene, ether,  $\text{CS}_2$ , and chloroform. Hardly sol. water. Volatile with steam. **Reactions**.—1. Decomposed by alcoholic potash, thus:

$(\text{CCl}_3\text{CN})_2 + 3\text{KOH} = \text{C}_2\text{N}_2(\text{OK})_2 + 3\text{CHCl}_3$ , forming chloroform and potassic cyanurate.—2. Boiled with alcoholic ammonia it reacts thus:  $\text{C}_2\text{N}_2(\text{CCl}_3)_2 + \text{NH}_3 = \text{HCCl}_3 + \text{C}_2\text{N}_2(\text{CCl}_3)_2\text{NH}_2$ . The latter body forms flat prisms (from alcohol) [166°]. It is sol. alcohol, ether, and benzene, scarcely sol. water. It is not a base.—3. When heated with alcoholic  $\text{NH}_3$  in sealed tubes at 110° the chloro-acetic paranitride reacts thus:  $\text{C}_2\text{N}_2(\text{CCl}_3)_2 + 2\text{NH}_3 = 2\text{CHCl}_3 + \text{C}_2\text{N}_2(\text{CCl}_3)_2(\text{NH}_2)_2$ . The diamide crystallises from alcohol either in long pyramids containing alcohol or in short six-sided prisms without alcohol of crystallisation. It melts at [236°]. It is sl. sol. ether and benzene, hardly sol. cold water. It forms a salt,  $\text{C}_2\text{N}_2(\text{CCl}_3)_2(\text{NH}_2)_2\text{HCl}$  2aq., crystallising in pearly plates. This salt is decomposed by boiling water.

Boiled with  $\text{NH}_4\text{Aq}$  it forms ammeline, or an isomeride  $\text{C}_2\text{N}_2(\text{OH})(\text{NH}_2)_2$ .—4. Heated with  $\text{NH}_4\text{Aq}$  at 120°, or alcoholic  $\text{NH}_3$  at 170° it forms  $\text{C}_2\text{N}_2(\text{OH})(\text{NH}_2)_2$ , v. AMMELINE.—5. Aqueous or alcoholic methylamine at 20° forms  $\text{C}_2\text{N}_2(\text{CCl}_3)_2\text{NHMe}$ . Small crystals [117°]. V. sol. alcohol, sol. benzene. Is not a base. With alcoholic ammonia at 110° it gives rise to  $\text{C}_2\text{N}_2(\text{CCl}_3)_2(\text{NH}_2)_2(\text{NHMe})$ . This body is also got from  $\text{C}_2\text{N}_2(\text{CCl}_3)_2(\text{NH}_2)_2$  and alcoholic methylamine. It forms colourless crystals [153°–155°]. 6. Alcoholic methylamine at 110° in a sealed tube forms  $\text{C}_2\text{N}_2(\text{CCl}_3)_2(\text{NHMe})_2$ . Small white crystals [207°]. Sol. alcohol and benzene. Forms salts.—7. Aqueous methylamine at 126° forms  $\text{C}_2\text{N}_2(\text{OH})(\text{NHMe})_2$ . Slender needles. Forms a platino-chloride  $(\text{B}^+\text{HCl}_2)_2\text{PtCl}_2$  (Weddige; v. also Hofmann, B. 18, 2770).

**CHLORO-ACETIC ALDEHYDE**  $\text{CH}_2\text{Cl.CHO}$ . (85°).

**Formation**.—1. From vinyl chloride,  $\text{HClO}$ , and  $\text{HgO}$  (Glinzky, Z. 1867, 678; 1868, 617; 1870, 647).—2. From di-chloro-ether and conc.  $\text{H}_2\text{SO}_4$  (Jacobsen, B. 4, 216).

**Preparation**.—A mixture of chloro-acetal (1000 g.) and dry oxalic acid (500 g.) is distilled at 100°–150° in an atmosphere of  $\text{CO}_2$ . The residue consists chiefly of oxalic ether, the distillate contains formic ether, oxalic acid, and chloro-acetic aldehyde. A portion (87°–91°) purified by fractional distillation is obtained in the form of a crystalline hydrate either by use of a freezing mixture or by means of  $\text{NaHSO}_4$ . Water of crystallisation is removed by distillation over  $\text{CaCl}_2$  or  $\text{CuSO}_4$ . The anhydrous aldehyde is, however, best obtained by distilling its polymeride (Natterer, M. 3, 442).

**Properties**.—Colourless liquid which combines with water, forming a crystalline hydrate,  $\text{CH}_2\text{Cl.CHO}$  2aq [43°–50°]. The V.D. (1.98) of the hydrate shows that it dissociates. It forms monoclinic crystals. Sol. water, alcohol, and ether; blisters the skin. Reduces ammoniacal  $\text{AgNO}_3$ , forming a mirror.

**Reactions**.—1. Oxidised by  $\text{HNO}_3$  to chloro-acetic acid. 2. Potassium cyanide gives an oil  $(\text{CH}_2\text{Cl.CHO})(\text{CH}_2\text{Cy.CHO})$  whence  $\text{HCl}$  forms acetic and chloro-oxo-propionic acids.—3. By heating alone or with some  $\text{H}_2\text{SO}_4$  it is converted into  $\alpha$ -di-chloro-crotonic aldehyde.—4.  $\text{HCl}$  passed into a mixture of chloro-acetic aldehyde and alcohol forms di-chloro-ether.

**Combinations**.—1. With alcohol it forms an alcoholate,  $\text{CH}_2\text{Cl.CH}(\text{OH})(\text{OEt})$ . (c. 94°). Also formed from di-chloro-ether with water (7 vols.) at 120° (Abeljan, A. 1<sup>e</sup>, 217). Repeated distillation converts it into  $\text{C}_2\text{H}_4\text{Cl}_2\text{O}$ , (164°).—2. With acetyl chloride:  $\text{CH}_2\text{Cl.CHCl}(\text{OAc})$ . (c. 147°). Formed also by reducing the corresponding compounds of chloral with acetyl chloride by Zn and acetic acid (Curie & Milliet, B. 9, 1611).—3. With bisulphite of soda:  $\text{C}_2\text{H}_4\text{ClONaHSO}_3$  2aq.; six-sided tables (from water). Separates from alcohol as a powder (containing 1 aq.). Boiling  $\text{Na}_2\text{CO}_3$  decomposes it without regenerating the chloro-acetic aldehyde.—4. With calomel:  $\text{C}_2\text{H}_4\text{ClO.Hg}_2\text{Cl}_2$ .

**Chloro-acetic paraldehyde**  $(\text{C}_2\text{H}_4\text{ClO})_3$ . (87°). (140°) at 10 mm. S.G. 2.77. V.D. 8.25 (calc. 8.31). An amorphous porcelain-like mass into which the aldehyde slowly changes on keeping (pro-

ably when not perfectly pure). It also separates from a solution of the hydrate in conc.  $\text{H}_2\text{SO}_4$ . Trimetric crystals,  $a:b:c = 1.51:1:0.941$ . Insol. water, sl. sol. cold alcohol, v. sol. ether. At  $245^\circ$  it is reconverted into the ordinary modification. Not acted upon by iron and acetic acid, by  $\text{AgOAc}$  and  $\text{HOAc}$ , by alcoholic  $\text{NH}_3$ , by  $\text{KOH}$  at  $100^\circ$ , or by cold  $\text{NaOEt}$  (Natterer, *M.* 6, 519).

#### Chloro-acetic orthoaldehyde

$\text{CH}_2\text{Cl.CH(OH)}_2$ . Contrary to analogy, the hydrate of chloro-acetic aldehyde does not seem to have the above formula, but appears to be  $\text{CH}_2\text{Cl.CH(OH).O.CH(OH).CH}_2\text{Cl}$  (*v. supra*). The di-alkylated derivatives of chloro-acetic orthoaldehyde are called acetals.

**Ethyl ether**  $\text{CH}_2\text{Cl.CH(OH)(OEt)}$ . *Chloro-aldehyde alcoholate*. ( $93^\circ$ – $95^\circ$ ). Formed by the action of water at  $120^\circ$  on dichlorinated ethyl oxide  $\text{CH}_2\text{Cl.CHCl.OEt}$ . On distillation it forms an anhydride,  $(\text{CH}_2\text{Cl.CH.OEt})_2\text{O}$ , ( $163^\circ$ – $165^\circ$ ), which is split up by conc.  $\text{H}_2\text{SO}_4$  into chloro-acetic aldehyde and alcohol. This body is also formed from di-chloro-di-ethyl ether and potash.

**Acetyl derivative of the ethyl ether**  $\text{CH}_2\text{Cl.CH(OEt)(OAc)}$ . ( $170^\circ$ ). From di-chloro-ethyl ether and silver acetate (Bauer, *A.* 134, 176).

**Methyl ether**  $\text{CH}_2\text{Cl.CH(OEt)(OMe)}$ . ( $137^\circ$ ). S.G.  $\pm 1.056$ . From di-chloro-ethyl ether and sodium methylate (Lieben, *A.* 146, 202).

**Di-ethyl ether**  $\text{CH}_2\text{Cl.CH(OEt)}_2$ . *Chloro-acetal*. ( $157^\circ$ ). S.G.  $\pm 1.042$ . V.D. 5.38 (calc. 5.29).

**Formation**.—1. When chlorine is passed into dilute alcohol (80 p.c.) for some time, on adding water a heavy oil separates. By fractional distillation this is found to consist chiefly of aldehyde, chloro-acetal, and di-chloro-acetal. The fraction  $120^\circ$ – $170^\circ$  is digested for several days with aqueous  $\text{KOH}$  and rectified (Lieben, *A. Ch.* [3] 56, 313; *Krey, Jena. Zeit.* 10, 84).—2. From di-chloro-ethyl ether  $\text{CH}_2\text{Cl.CHCl.OEt}$  and  $\text{NaOEt}$  (Lieben, *A.* 146, 193; Natterer, *M.* 3, 444); or by long boiling with alcohol (Paterno, *A. Mazara*, *B.* 6, 1202).—3. From di-chloro-ethylene and alcoholic  $\text{NaOEt}$  at  $40^\circ$ – $50^\circ$  (Kien, *J.* 1876, 336).—4. By warming chloro-acetic aldehyde with alcohol (Natterer, *M.* 5, 497). **Properties**.—Aromatic liquid, insol. water, sol. alcohol. Not attacked by aqueous  $\text{KOH}$ . Does not pp.  $\text{AgNO}_3$ .—**Reactions**.—1.  $\text{NaOEt}$  at  $150^\circ$  gives  $\text{CH}_2\text{Cl.CH(OEt).CH(OEt)}_2$ .—2. Sodium forms  $\text{CH}_2\text{Cl.CH(OEt)}$  (Wislicenus, *A.* 192, 106).—3. Boiling with powdered zinc gives  $\text{EtCl}$  and alcohol.—4. Heating with oxalic acid gives chloro-acetic aldehyde and oxalic ether.  $\text{HOAc}$  acts similarly.—5.  $\text{HCl}$  gives di-chloro-ethyl ether  $\text{CH}_2\text{Cl.CHCl.OEt}$ .—6. Poured upon bleaching powder, no action ensues, but upon heating over water bath a reaction takes place and a greenish liquid collects in the receiver. This distillate presently decomposes, the products being chlorine,  $\text{HCl}$ , uncomposed chloro-acetal, di- and tri-chloro-acetals, chloroform, and an aldehyde (Goldberg, *J.* pr. 132, 109).

**Di-chloro-acetic aldehyde**,  $\text{CHCl}_2\text{CHO}$ . Mol. w. 113. ( $89^\circ$ ).

**Formation**.—1. By distilling di-chloro-acetal with  $\text{H}_2\text{SO}_4$  (Grimaux, *A. Adam, Bl.* 34, 29; Paterno, *Z.* 1868, 667).—2. By boiling  $\text{CCl}_2\text{CH.OMe}$  with dilute  $\text{H}_2\text{SO}_4$  (Denaro, *G.* 14, 119).—3. By distilling its hydrate obtained by chlorination

of chloro-acetic paraldehyde (*v. di-chloro-acetic orthoaldehyde*) with  $\text{H}_2\text{SO}_4$ .

**Properties**.—Liquid, which, in presence of some  $\text{HCl}$ , gradually changes to an amorphous solid variety, which at  $120^\circ$  returns to the liquid form.

**Reactions**.—1. Oxidised by  $\text{HNO}_3$  to dichloro-acetic acid.—2.  $\text{PCl}_5$  forms  $\text{CHCl}_2\text{CHCl}_2$  ( $147^\circ$ ) (Paterno, *Z.* 1868, 667).

#### Di-chloro-acetic paraldehyde

$(\text{CHCl}_2\text{CHO})_3$ . ( $130^\circ$ ). S.G. 1.69. From di-chloro-acetic aldehyde (or di-chloro-acetal) in presence of  $\text{H}_2\text{SO}_4$  in the cold (Jacobsen, *B.* 8, 87; cf. Krey, *J.* 1876, 475). Hexagonal pyramids (from alcohol). V. sol. hot alcohol. May be sublimed, but at  $240^\circ$  in a sealed tube, or with conc.  $\text{H}_2\text{SO}_4$  at  $130^\circ$ , it changes to liquid di-chloro-acetic aldehyde.

#### Amorphous polymericide ( $\text{CHCl}_2\text{CHO}$ )<sub>n</sub>

Formed spontaneously by the polymerisation of (impure?) di-chloro-acetic aldehyde (Friedrich, *A.* 206, 252). Paraffin-like mass, insol. water, m. sol. ether, sl. sol. hot alcohol. Does not melt below  $200^\circ$ . Converted by heat into ordinary di-chloro-acetic aldehyde.

#### Di-chloro-acetic orthoaldehyde

$\text{CHCl}_2\text{CH(OH)}_2$ . *Di-chloro-acetic aldehyde hydrate*. ( $43^\circ$ ) (F.); ( $57^\circ$ ) (Denaro, *G.* 14, 120) (c.  $120^\circ$ ). Formed as a by-product in the preparation of tri-chloro-butyric aldehyde by the action of chlorine upon paraldehyde (Friedrich, *A.* 206, 251). Micaceous scales. V. sol. water and ether. Oxidised by  $\text{HNO}_3$  to di-chloro-acetic acid. Conc.  $\text{H}_2\text{SO}_4$  converts it into di-chloro-acetic aldehyde and its amorphous polymericide.

**Di-ethyl ether**  $\text{CHCl}_2\text{CH(OEt)}_2$ . *Di-chloro-acetal*. Mol. w. 187. ( $184^\circ$ ). V.D. 6.45 (calc. 6.44). S.G.  $\pm 1.138$ . Formed by chlorinating alcohol (*v. supra*) or acetal (Lieben, *A.* 104, 114; Pinner, *B.* 5, 148; Krey, *J.* 1876, 474). Also from tri-chloro-ethyl ether  $\text{CHCl}_2\text{CHCl.OEt}$  and  $\text{NaOEt}$  (Jacobsen, *B.* 4, 217).

**Reactions**.—1. Zinc-ethyl at  $140^\circ$  gives propylene, ethylene, and other gases, leaving ether: (Paterno, *C. R.* 77, 458).—2.  $\text{PCl}_5$  gives tri-chloro-ethyl ether  $\text{CHCl}_2\text{CHCl.OEt}$ .—3.  $\text{NaOEt}$  gives the tetra-ethyl derivative of ortho-glyoxal  $\text{CH(OEt)}_2\text{CH(OEt)}_2$  (Pinner, *B.* 5, 151).—4. Conc.  $\text{H}_2\text{SO}_4$  or  $\text{HClAq}$  converts it into di-chloro-acetic aldehyde. Fuming  $\text{H}_2\text{SO}_4$  forms a crystalline compound  $\text{C}_2\text{H}_2\text{Cl}_2\text{O}_3$  ( $129^\circ$ ) (Grabowsky, *B.* 6, 1071). According to Pinner (*A.* 179, 34) di-chloro-acetal is not converted into di-chloro-acetic aldehyde by  $\text{H}_2\text{SO}_4$ , and does not give di-chloro-acetic acid on oxidation by  $\text{HNO}_3$ .

#### Tri-chloro-acetic aldehyde v. CHLORAL

**Tri-chloro-acetic orthoaldehyde v. CHLORAL hydrate**

*Di-ethyl ether*  $\text{CCl}_3\text{CH(OEt)}_2$  (*v. p.* 4).

An isomeride, possibly having the constitution  $\text{CHCl}_2\text{CCl(OEt)}_2$  ( $72^\circ$ ) (P.); ( $83^\circ$ ) (E), ( $230^\circ$ ), is formed as a secondary product in the preparation of di-chloro-acetal by the chlorination of 80 p.c. alcohol (Paterno, *C. R.* 67, 785; Lieben, *A.* 104, 114; Krey, *J.* 1876, 475). Needles (from ether). Volatile with steam. It is doubtful whether it yields chloral on treatment with  $\text{H}_2\text{SO}_4$ ; such a reaction would indicate the same formula as that assigned to the liquid isomeride (*v. p.* 4).

**TRI-CHLORO-ACETIC ANHYDRIDE** v. *Anhydride of Tri-chloro-acetic acid*.

**CHLORO-ACETO-ACETIC ETHER**  $C_2H_2ClO_4$ , i.e.  $CH_3.CO.CHCl.CO.Et$  or  $CH_2Cl.CO.CH.CO.Et$ . (194°). S.G. 1.19. Formed, together with  $SO_2$ , and HCl, by the action of  $SO_2Cl_2$  (1 mol.) or of Clupon aceto-acetic ether (1 mol.) (Allihn, B. 11, 568; Merves, A. 245, 58). Liquid. Alcohol KOH liberates chloro-acetic acid. (a)-Naphthylamine forms  $C_{10}H_7NO_2Cl$  [75°] (Bender, B. 20, 2747). Fuming  $HNO_3$  forms chloro-nitroso-aceto-acetic ether  $CH_3.CO.CCl(NO).CO.Et$  (?) (Prüpper, A. 222, 48). Phenyl-hydrazine in ethereal solution forms  $C_6H_5.N_2O_2$  [51°], which is probably  $CH_3.C(N.Ph).CH.CO.Et$ , which may be reduced to oxy-phenyl-methyl-pyrazole.

**Metallic compounds**.—Formed as precipitates by shaking the ether with ammoniacal solutions of the metallic salts.  $(C_2H_2ClO_4)_2Cu$ : green leaflets.  $(C_2H_2ClO_4)_2Mg$ : white needles.  $(C_2H_2ClO_4)_2Ni$ : light-green powder.  $(C_2H_2ClO_4)_2Co$ : light-red powder (Hensgen, B. 12, 1300).  $C_2H_2ClO_4Na$ : crystalline powder, v. sol. alcohol (Conrad, A. Guthzeit, B. 16, 1564).

**Di-chloro-aceto-acetic ether**  $CH_2.CO.CCl_2.CO.Et$  or  $CHCl_2.CO.CH_2.CO.Et$ . (206°). S.G. 1.233. Formed, together with  $SO_2$  and HCl, by the action of  $SO_2Cl_2$  (2 mols.) on aceto-acetic ether (2 mol.) (Allihn, B. 11, 567). Formed also by chlorinating aceto-acetic ether (Conrad, A. 186, 232). Liquid. Decomposed by dilute HCl at 180° into  $CO_2$ , alcohol, and di-chloro-acetone. KOH gives di-chloro-acetic and acetic acids. Decomposed by KCN into HCN, acetic ether, and potassium di-chloro-acetate (James, A. 240, 65; C. J. 51, 287). Di-chloro-aceto-acetic acid does not form metallic salts, nor does it react with aldehydes (difference from di-bromo-aceto-acetic ether).

**Tri-chloro-aceto-acetic ether**  $C_2HCl_3O_4$ , (225°). From aceto-acetic ether and Cl in daylight (Merves, A. 245, 70). With NaOEt it gives di-chloro-acetic ether.

**CHLORO-ACETOL** v. **DI-CHLORO-PROPANE**.

**CHLORO-ACETONE**  $C_2H_2ClO_3$  i.e.  $CH_2.CO.CHCl$ . (118°). S.G. 1.158 (Cloeze).

**Formation**.—1. By electrolysis of a mixture of acetone and HCl (Riche, C. R. 49, 176).—2. From acetone and  $HClO$  (Mulder, B. 5, 1007).—3. By passing chlorine (1 mol.) into well-cooled acetone (M.).—4. By dissolving di-chloro-propylene  $CH_2Cl.CCl.CH_2$  in conc.  $H_2SO_4$  and distilling the product with water (Henry, B. 5, 190, 965).—5. From bromo- or chloro-propylene by the action of hypochlorous acid and  $HgO$  (Linnemann, A. 188, 122).—6. By oxidation of propylene chlorhydrin (from propylene glycol) with  $K_2Cr_2O_7$  and  $H_2SO_4$  (Morley, A. Green, B. 18, 24).

**Preparation**.—By passing chlorine into acetone at 15° (Cloeze, A. Ch. [6] 9, 145).

**Properties**.—Pungent oil; v. sl. sol. water. According to Cloeze it is not pungent when quite pure, and the pungency can be removed by washing with very weak alkali. Volatile with steam. It gives a splendid crimson colour with solid KOH, or a strong aqueous solution of KOH. With  $NaHSO_3$  it forms crystalline  $C_2H_2Cl(OH)(SO_3Na)$  (Barbaglia, B. 6, 224).

**Reactions**.—1. Zn and  $HCl$  reduce it to acetone.—2. Moist  $Ag_2O$  oxidises it to glycollic,

acetic, and formic acids.—8.  $K_2SO_4$  gives  $CH_2.CO.CH_2.SO_4K$ .—4. Potassium acetate forms  $CH_2.CO.CH_2.OAc$ .—5. Alcoholic KCN produces  $CH_2.CO.CH_2.CN$ .—6. Fuming  $HNO_3$  forms crystalline nitroso-chloro-acetone  $CH_2Cl.NO$  [110°] (Glutz, J. pr. [2] 1, 141).—7. Alcoholic ammonium sulphocyanide gives the crystalline sulphocyanide [114°] of imido-propyl sulphocyanide  $CH_2.C(NH).CH_2.SCN$  [42°] (Norton & Tcherniak, Bl. [2] 33, 203).—8. Barium sulphocyanide forms  $CH_2.CO.CH_2.SCN$  which is an oil (Tcherniak & Hellon, B. 16, 349).—9. Bromine at 100° forms chloro-tri-bromo-acetone.—10. Ammonia forms a compound  $(CH_2.CO.CH_2.NH_2)_2$  which gives methylamine on distillation with potash (Cloeze). 11. Chloro-acetone (2 mols.) added to an aqueous solution of (1, 3, 4)-tolylene-diamine at 60° forms methyl-toluquinoxaline  $C_{12}H_{12}N_2O$  [54°]

(Hinsberg, A. 237, 368).—12. Alcoholic  $KOBz$  forms  $CH_2.CO.CH_2.OBz$  (245° at 380mm.) (van Romburgh, R. T. C. 1, 53).—13. Conc.  $HClNa$  forms the cyanhydrin  $CH_2.C(OH)(CN).CHCl$  which is the nitrile of chloro-oxy-isobutyric acid (chloro-acetic acid) (C. Bischoff, B. 5, 865).

Isomeride of chloro-acetone  $C_2H_2ClO_3$  i.e.

$CH_2Cl.CH_2CH_2$  (?) *Epichlorhydrin* (119°). S.G. 1.194. Obtained from glycerin dichlorhydrin  $CH_2Cl.CH_2(OH).CH_2Cl$  and warm conc. KOH (Prevost, P. [2] 12, 160). Liquid. Combines with HCl, water, and HOAc forming derivatives of di-chlorhydrin. With alcoholic  $NH_3$  it forms  $C_2H_2Cl_2N_2O$  (Cloeze, A. Ch. [6] 9, 145).  
*Di-chloro-acetone*  $CHCl_2.CO.CH_2$ . Mol. w. 127. (120°). S.G. 1.234.

**Formation**.—By heating di-chloro-aceto-acetic ether with water at 180° (Conrad, A. 186, 235) or by boiling it with  $HClAq$  for 5 hours (V. Meyer, B. 15, 1165).

**Preparation**.—By the prolonged action\* of chlorine upon well-cooled acetone (Pittig, A. 110, 40; 133, 112; Mulder, B. 5, 1007; Cloeze, A. Ch. [6] 9, 145).

**Properties**.—Pungent liquid, sl. sol. water. Combines with bisulphite of soda forming  $C_2H_2Cl_2(OH)(SO_3Na)_2$ .

**Reactions**.—1. Ammonia forms the compound  $CH_2.CO.CHCl(NH_2)$  which yields methylamine when distilled with potash.—2.  $PCl_5$  gives tetra-chloro-propylene and a small quantity of penta-chloro-propylene.—3.  $KHS$  gives a yellow viscid body  $C_2H_2SO_4$ , the alcoholic solution of which gives with lead acetate a red pp.  $C_2H_2SO_4PbO_2$  (Mulder, B. 5, 1008).—4. *Hydroxylamine* forms acetoximic acid  $CH_2.C(=OH).CH(OH)$  (v. vol. 1, p. 39).—5. Water at 200° gives lactic acid (Linnemann & Zotta, A. 159, 248).—6. Potash splits it up into acetic and formic acids.—7. HCN gives the cyanhydrin  $CH_2.C(OH)(CN).CHCl$ , or the nitrile of di-chloro-oxy-isobutyric acid (Bischoff, B. 8, 1339).—8. Aqueous KCN gives crystalline tufts of  $(C_2H_2Cl_2O)_2HCN$  (Glutz & Fischer, J. pr. [2] 4, 52).

Isomeride of di-chloro-acetone  $C_2H_2Cl_2O$ . [44°]. (c. 168°). The entire product of the action of chlorine on cooled acetone has the composition of di-chloro-acetone, although it boils between 117° and 170°. This appears to be due

to the presence of this crystalline isomeride. It only differs from *s*-di-chloro-acetone, derived from dichlorhydrin, in yielding with bromine a di-chloro-di-bromo-acetone identical with that obtained from *u*-di-chloro-acetone, and not with that obtained from the said *s*-di-chloro-acetone (Barbaglia, *B.* 7, 468; Cloez). This compound could not be obtained by Bischoff (*B.* 8, 1832).

Another isomeride  $\text{CHCl} \cdot \text{CH} \cdot \text{CHCl}$  (?) Chloro-epichlorhydrin (?) (170°), is formed by chlorinating epichlorhydrin (Cloez, *A. Ch.* [6] 9, 145). With  $\text{NH}_3$  it forms unstable  $\text{C}_2\text{H}_4\text{Cl}_2\text{NO}_2$ . *s*-Di-chloro-acetone  $\text{CH}_2\text{Cl} \cdot \text{CO} \cdot \text{CH}_2\text{Cl}$  [44°] (173° cor.). V.P. 63.2.

**Formation.**—1. By the oxidation of the corresponding dichlorhydrin of glycerin  $\text{CH}_2\text{Cl} \cdot \text{CH}(\text{OH}) \cdot \text{CH}_2\text{Cl}$  with  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$ . Purified by means of its crystalline compound with  $\text{NaHSO}_4$ , which is subsequently decomposed by  $\text{Na}_2\text{CO}_3$ . The yield is very small (Glutz a. Fischer, *J. pr.* [2] 4, 52; Hömann, *B.* 13, 1707; Markownikoff, *A.* 208, 349).—2. By the union of  $\text{HClO}$  with  $\alpha$ -chloro-allyl chloride (di-chloro-propylene)  $\text{CH}_2\text{Cl} \cdot \text{CHCl} \cdot \text{CH}_2$  and  $\text{HClO}$  (Henry, *C. R.* 94, 1428).—3. From *s*-di-iodo-acetone and  $\text{AgCl}$  (Voelker, *A.* 192, 89).

**Properties.**—Long needles or trimetric tables. Extremely pungent; blisters the skin. M. sol. water, v. sol. alcohol and ether. With bisulphite of soda it forms long four-sided prisms of  $\text{C}_2\text{H}_3\text{Cl}_2(\text{OH})(\text{SO}_3\text{Na})$  3aq.

**Reactions.**—1. KI forms di-iodo-acetone [61°].—2. Dry KCN added to its ethereal solution forms crystalline tetra-chloro-di-acetone cyanhydrin  $(\text{C}_2\text{H}_3\text{Cl}_2\text{O})_2\text{HCN}$  which differs from the isomeric body obtained from *u*-di-chloro-acetone in being insol. water (G. a. F.).—3. HCN forms  $(\text{CH}_2\text{Cl})_2\text{C}(\text{OH})\text{CN}$ , the nitrile of di-chloro-oxy-isobutyric (di-chloro-acetonic) acid.—4. Oxidised by  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  to chloro-acetic acid.

According to Cloez (*A. Ch.* [6] 9, 145) successive treatment with bromine and  $\text{HgCl}_2$  gives tetra-chloro-acetone, but the tetra-chloro-acetone prepared in this way from the di-chloro-acetone obtained from dichlorhydrin is different from that obtained from di-iodo-acetone. They also give different penta-chloro-acetones when treated with chlorine in sunlight. Cloez considers the derivative from dichlorhydrin to be a pseudo-di-chloro-acetone

$\text{CH}_2\text{Cl} \cdot \text{CH} \cdot \text{CHCl}$ . It does not combine with  $\text{HOAc}$ , but reacts violently with  $\text{HCl}$ , although the product, exposed over  $\text{H}_2\text{SO}_4$ , is reconverted into *u*-di-chloro-acetone.

Tri-chloro-acetone  $\text{CCl}_3 \cdot \text{CO} \cdot \text{CH}_2$  (180°) (Combes).

**Formation.**—Obtained in an impure state by passing chlorine into acetone that is not kept cool, especially if the chlorine be somewhat moist, or the acetone be mixed with methyl alcohol (crude wood spirit) (Bischoff, *B.* 8, 1831). The crude product of the oxidation of isobutyl alcohol with chromic mixture may also be used (Krämer, *B.* 7, 252).

**Preparation.**—1. By passing chlorine into an

aqueous solution of sodium citraconate at 100° (Gottlieb a. Morawsky, *J. pr.* [2] 12, 303).—2. By the action of  $\text{NaOH}$  (1 mol.) upon hexa- $\omega$ -chloromethylene di-methyl diketone (hexa-chloro-acetyl-acetone)  $(\text{CCl}_3\text{CO})_2\text{CH}_2$  (Combes, *A. Ch.* [6] 12, 239).

**Properties.**—Liquid, heavier than water, with fragrant odour. Converted by ammonia into chloroform and acetamide. Does not unite with  $\text{NaHSO}_4$ ; but with  $\text{HCN}$  it forms  $\text{CCl}_3 \cdot \text{CMe}(\text{OH})\text{CN}$  (Bischoff). It unites readily with water, forming a hydrate  $\text{C}_2\text{H}_3\text{Cl}_2\text{O} \cdot 2\text{H}_2\text{O}$  [44°] crystallising in four-sided prisms, which is resolved by distillation or by dry  $\text{HCl}$  into its constituents. The product of the chlorination of acetone boils at 172°, and has S.G. 1.418. According to Cloez it is a mixture; for it solidifies incompletely on cooling, when it deposits needles [c. -5°]. With aniline and  $\text{KOH}$  it gives phenyl-carbamine, showing the presence of  $\text{CCl}_3 \cdot \text{CO} \cdot \text{CH}_2$ . Successive treatment with ammonia and  $\text{KOH}$  gives di-chloro-methyl-amine, indicating the presence of  $\text{CHCl}_2 \cdot \text{CO} \cdot \text{CH}_2\text{Cl}$ .

Tri-chloro-acetone  $\text{CHCl}_2 \cdot \text{CO} \cdot \text{CH}_2\text{Cl}$  (172°). From *u*-di-chloro-acetone by treating with bromine and heating the resulting  $\text{CHCl}_2 \cdot \text{CO} \cdot \text{CHCl}_2$  Br with  $\text{HgCl}_2$  in presence of alcohol (Cloez). Gives no chloroform with ammonia, nor phenyl-carbamine with aniline and  $\text{KOH}$ .

*u*-Tetra-chloro-acetone  $\text{CH}_2\text{Cl} \cdot \text{CO} \cdot \text{CCl}_3$  (181°). S.G. 1.432. Formed by saturating acetone containing methyl alcohol or wood spirit with chlorine in daylight, the temperature being allowed to rise (Bouis, *A. Ch.* [3] 21, 111). The fraction boiling at 100°-180° is exposed to a low temperature in contact with water, whereupon the hydrate of tri-chloro-acetone crystallises out first, then a compound of this with tetra-chloro-acetone hydrate  $(\text{C}_2\text{H}_3\text{Cl}_2\text{O})(\text{C}_2\text{H}_3\text{Cl}_2\text{O})$  6aq [32°], and finally large prisms of the hydrate of tetra-chloro-acetone  $\text{C}_2\text{H}_3\text{Cl}_2\text{O} \cdot 4\text{aq}$  [39°] (c. 179°), which may be resolved by dry  $\text{HCl}$  into tetra-chloro-acetone and water.

**Properties.**—Colourless hygroscopic liquid, sol. water, with pungent odour. Readily volatile with steam. Turned brown by air and light. Partially decomposed by distillation. With aniline and  $\text{KOH}$  it yields phenyl carbamine. Aqueous ammonia at a low temperature forms chloroform and chloro-acetamide.

*s*-Tetra-chloro-acetone  $\text{CHCl}_2 \cdot \text{CO} \cdot \text{CHCl}_2$  (180°). S.G. 1.43. Formed by treating *u*-di-chloro-acetone, or the *s*-di-chloro-acetone derived from *s*-di-iodo-acetone, with bromine and decomposing the resulting  $\text{CHCl}_2 \cdot \text{CO} \cdot \text{CHBr}_2$  with  $\text{HgCl}_2$  in alcoholic solution at 100°. Purified by conversion into its crystalline hydrate [48°] and subsequent dehydration by dry  $\text{HCl}$  (Cloez). This tetra-chloro-acetone does not give the chloroform and carbamine reactions. The di-chloro-di-bromo-derivative obtained by the action of bromine on dichlorhydrin yields with  $\text{HgCl}_2$  an oil which is not attacked by ammonia. The product of the oxidation of dichlorhydrin gives with bromine  $\text{CHCl}_2 \cdot \text{Br} \cdot \text{CO} \cdot \text{CHCl}_2 \cdot \text{Br}$  (Markownikoff), whence  $\text{HgCl}_2$  gives a fuming liquid (180°); this liquid does not combine with  $\text{NaHSO}_4$ , but yields with ammonia di-chloro-acetamide, and with aniline di-chloro-acetanilide. Cloez con-

siders that it is isomeric, but not identical with *s*-tetra-chloro-acetone; thus it might be

Penta-chloro-acetone  $\text{CCl}_2\cdot\text{CO}\cdot\text{CHCl}_2$ . (192°). S.G.  $\frac{1}{4}$  1.576. S. 15.

**Formation.**—1. By passing chlorine into a strong solution of sodium citraconate (Plantamour, *Gm.* 11, 440).—2. By the action of HCl and KClO<sub>3</sub> on various organic compounds, *e.g.* quinic, citric, gallic, and salicylic acids, pyrogallol, quinine, indigo, tyrosine, and muscular flesh (Städeler, *A.* 111, 277).—3. By the action of chlorine in sunlight upon commercial acetone or on di-chloro-acetone (Cloeze, *sen.*, *A.* 111, 180; Cloeze, *jun.*, *Bl.* [2] 39, 637). Pure acetone gives only di-chloro-acetone when chlorinated at 100° in sunlight (Fittig).

**Preparation.**—A solution of citric acid in  $1\frac{1}{2}$  pts. water is allowed to fall drop by drop down a tube packed with pumice heated to 100°, up which a current of dry chlorine is passing (Cloeze, *jun.*, *A.* Ch. [6] 9, 145).

**Properties.**—Colourless liquid, smelling (after exposure to air) like chloral. With water at 4° it forms a crystalline hydrate  $\text{C}_2\text{HCl}_3\text{O}\cdot 4\text{aq}$  [15°], which, on fusion, separates into water and penta-chloro-acetone. Penta-chloro-acetone separates completely from its aqueous solution at 60°. Penta-chloro-acetone dissolves a little water, but on warming this separates as globules.

**Reactions.**—1. Ammonia gives chloroform and di-chloro-acetamide [95°] (235°).—2. Aniline and KOH give phenyl-carbamine.—3. KOH gives di-chloro-acetic acid, KCl, and  $\text{K}_2\text{CO}_3$ .

Isomeride of penta-chloro-acetone

$\begin{array}{c} \text{O} \\ \diagup \quad \diagdown \\ \text{CCl}_2\text{CH}\cdot\text{CCl}_2(?) \end{array}$  Tetra-chloro-epichlorhydrin. (186°). S.G.  $\frac{1}{4}$  1.617. By the action of chlorine in sunlight on the *s*-di-chloro-acetone from di-chlorhydrin (Cloeze, *jun.*, *Bl.* [2] 39, 639). Pungent liquid. With ammonia it gives tri-chloro-acetamide [139°] (235°–240°) but no chloroform.

Another isomeride of penta-chloro-acetone

$\begin{array}{c} \text{O} \\ \diagup \quad \diagdown \\ \text{CHCl}_2\text{CCl}\cdot\text{CCl}_2(?) \end{array}$  (178°). From di-chloro-propylene oxide and chlorine (Cloeze, *jun.*, *A.* Ch. [6] 9, 145). Fuming liquid. With ammonia it gives di-chloro-acetamide, but no chloroform.

Hexa-chloro-acetone  $\text{CCl}_3\cdot\text{CO}\cdot\text{CCl}_3$ . [–2°]. (208°). S.G.  $\frac{1}{4}$  1.744. V.D. 9.62. Formed by saturating a conc. aqueous solution of citric acid with chlorine in sunshine (Plantamour, *B.* J. 26, 428). The yield is 25 p.c. of the weight of citric acid. Formed also by the action of chlorine on (commercial) acetone in sunlight. On distilling the product a considerable quantity of hexa-chloro-benzene is usually formed.

**Properties.**—Limpid liquid, which has a feeble odour in the cold, but becomes very pungent when warmed. Solidifies when cooled in large plates. Sl. sol. water. Forms a crystalline hydrate  $\text{C}_2\text{Cl}_6\text{O}\cdot\text{aq}$  [16°] almost insol. water.

**Reactions.**—1. With aqueous ammonia it forms chloroform and tri-chloro-acetamide.—2. Aniline forms chloroform and tri-chloro-acet-anilide.—3. Water at 120° splits it up into chloroform and tri-chloro-acetic acid.—4. Potash

gives CO<sub>2</sub> and tri-chloro-acetic acid.—5. With *o*-toluidine it forms tri-chloro-acetyl *o*-toluidine  $\text{C}_6\text{H}_4\text{Me}\cdot\text{NH}\cdot\text{CO}\cdot\text{CCl}_3$  [67°]; with *p*-toluidine it forms the isomeric body [80°].—6. Diethylamine gives  $\text{NEt}_2\cdot\text{CO}\cdot\text{CCl}_3$  [90°].—7. Methylamine forms  $\text{NHC}_2\text{H}_5\cdot\text{CO}\cdot\text{CCl}_3$  [45°].—8. Ethylene-diamine gives  $\text{NH}_2\cdot\text{C}_2\text{H}_4\cdot\text{NH}\cdot\text{CO}\cdot\text{CCl}_3$  [200°].—9. Urea (1 mol.) at 150° forms  $\text{CO}\cdot\text{NH}\cdot\text{CO}\cdot\text{CCl}_3$ .

Isomeride of hexa-chloro-acetone

$\begin{array}{c} \text{O} \\ \diagup \quad \diagdown \\ \text{CCl}_2\text{CCl}\cdot\text{CCl}_2(?) \end{array}$  (c. 205°). This substance appears to be formed, together with hexa-chloro-benzene, by the action of chlorine on epichlorhydrin in sunlight (Cloeze, *jun.*).

CHLORO-ACETONIC ACID *v.* CHLORO-OXY-ISOBUTYRIC ACID.

CHLORO-ACETONITRILE *v.* Nitrile of CHLORO-ACETIC ACID.

*o*-CHLORO-ACETOPHENONE

$\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{CH}_2\text{Cl}$ . Phenacyl chloride. Phenyl-chloro-methyl ketone. [59°]. (245°). Formed, together with di- and tri-chloro-acetophenone, by passing chlorine into boiling acetophenone. The fraction (240°–250°) solidifies on cooling, and is recrystallised from dilute alcohol (Gräbe, *B.* 4, 35; Städler, *B.* 10, 1830; Gautier, *C. R.* 102, 1218). Colourless trimetric plates; *a:b:c* = .9957:1:2.135 (Friedlander); *v.* a. sol. alcohol and ether, insol. water. Its vapour is pungent.

**Reactions.**—1. KOAc forms the acetyl derivative of *o*-oxy-acetophenone,  $\text{C}_6\text{H}_3\cdot\text{CO}\cdot\text{CH}_2\text{OAc}$ . 2.  $\text{PCl}_5$  forms di-chloro-styrene  $\text{C}_6\text{H}_4\cdot\text{CHCl}\cdot\text{CHCl}_2$ . 3. Chromic acid oxidises it to benzoic acid.—4. Ammonia passed into its ethereal solution forms two isomerides  $\text{C}_6\text{H}_4\cdot\text{N}\cdot\text{CO}$  [117°] and [155°]. Boiling aqueous ammonia forms (a)-phenyl-ampinitrile or isoindole  $\text{C}_8\text{H}_7\cdot\text{N}$  [195°], which crystallises from alcohol in blue monoclinic needles (V. Meyer *a.* Treadwell, *B.* 16, 342).—5. (1, 3, 4)-Tolylene-diamine gives phenyl-toluquinoxaline  $\text{C}_8\text{H}_7\text{Me}\cdot\text{N}(\text{CH}_2\text{N}(\text{C}_6\text{H}_4))$  [135°] (Hinsberg, *A.* 237, 370).

*p*-Chloro-acetophenone  $[\text{4:1}]\text{C}_6\text{H}_4\cdot\text{Cl}\cdot\text{CO}\cdot\text{CH}_2$ . Chloro-phenyl methyl ketone. [20°]. (231°). S.G.  $\frac{1}{4}$  1.19. From chloro-benzene, acetyl chloride, and  $\text{Al}_2\text{Cl}_3$  (Gautier, *Bl.* [2] 43, 602). *V. al.* sol. water, miscible with alcohol and ether.  $\text{KMnO}_4$  oxidises it to *p*-chloro-benzoic acid.

Di-*o*-chloro-acetophenone  $\text{C}_6\text{H}_3\cdot\text{CO}\cdot\text{CHCl}_2$ . (248°). S.G.  $\frac{1}{4}$  1.338. From di-chloro-acetyl chloride, benzene, and  $\text{Al}_2\text{Cl}_3$  (Gautier, *C. R.* 103, 812).

Tri-*o*-chloro-acetophenone  $\text{C}_6\text{H}_2\cdot\text{CO}\cdot\text{CCl}_3$ . (249°). S.G.  $\frac{1}{4}$  1.427. From tri-chloro-acetyl chloride (60 g.), benzene (100 g.), and  $\text{Al}_2\text{Cl}_3$  (Gautier, *C. R.* 103, 812). *v. al.* slowly oxidised by  $\text{KMnO}_4$  to benzoic acid.

TRI-*o*-CHLORO-ACETOPHENONE *o*-CABB-OXYLIC ACID  $\text{CCl}_3\cdot\text{CO}\cdot\text{C}_6\text{H}_2\cdot\text{CO}_2\text{H}$ . [144°]. Formed by passing chlorine into a hot solution of phthalyl-acetic acid in diluted HOAc (Michael *a.* Gabriel, *B.* 10, 1556). Decomposed by alkalis into chloroform and phthalic acid.

CHLORO-ACETOETHANONE *v.* THENYL CHLORO-METHYL KETONE.

CHLORO-ACETOXIM  $(\text{CH}_2)_3\text{C}\cdot\text{NOCl}$ . Acet-chlorozim. (184° uncor.). when quickly heated it explodes with violence. V.D.  $\frac{1}{4}$  1 (for 3.7). Obtained by adding a solution of hypochlorous

acid to an aqueous solution of acetoxim at 0°; the liquid that separates is washed with water, and dried over  $\text{CaCl}_2$ . Colourless mobile liquid of pleasant odour, which solidifies in a freezing-mixture of solid  $\text{CO}_2$  and ether, to colourless prisms. V. sol. alcohol and ether, v. sl. sol. water. Warmed with HCl or  $\text{HI}$  it sets free the halogens (Möhlau & Hoffmann, *B.* 20, 1505).

**TRI-CHLORO- $\beta$ -ACETYL-ACRYLIC ACID** v. TRI-CHLORO-PHENOMALIC ACID.

**TRI-CHLORO-ACETYL-BENZOIC ACID** v. TRI-CHLORO-ACETOPHENONE CARBOXYLIC ACID.

**CHLORO-ACETYL BROMIDE**  $\text{CH}_2\text{Cl.CO.Br}$ . (127°) (W.); (134°) (G.). S.G.  $\frac{2}{3}$  1.913. Prepared by adding bromine (160 g.) to chloro-acetic acid (94 g.) and red phosphorus (15 g.) (De Wilde, *A.* 130, 872; 132, 173; *Gal.* *A.* 132, 180). Fuming liquid. With water it forms HBr and chloro-acetic acid; alcohol gives EtBr and chloro-acetic ether.

• Tri-chloro-acetyl bromide  $\text{CCl}_3\text{CO.Br}$ . (140°) (H.); (143°) (G.). S.G.  $\frac{15}{16}$  1.900. From PBr<sub>3</sub> (2 mol.) and tri-chloro-acetic acid (3 mol.). 300 grms. of the acid give 200 grms. bromide (Hofferichter, *J. pr.* 128, 196; *Gal.* *C. R.* 76, 1019; *Bl.* [2] 20, 11). Water decomposes it into HBr and tri-chloro-acetic acid; alcohol gives EtBr and tri-chloro-acetic ether.

**CHLORO-ACETYL CHLORIDE**  $\text{CH}_2\text{Cl.CO.Cl}$ . Mol. w. 113. (107°). S.G.  $\frac{2}{3}$  1.495. Formed by the action of chlorine on acetyl chloride in sunlight (Wurtz, *A.* 102, 93); or, together with di-chloro-acetyl chloride by boiling acetyl chloride with  $\text{PCl}_3$  (Michael, *J. pr.* [2] 35, 95). Formed also by treating chloro-acetic acid with  $\text{PCl}_3$  (De Wilde, *A.* 130, 372). Liquid, converted by water into HCl and chloro-acetic acid; and by dry ammonia into chloro-acetamide.

*Reactions.*—1. Successive treatment with zinc methyl and water forms methyl-isopropyl-carbinol (Bogomoletz, *B.* [2] 34, 330).—2. With *o*-amido-phenol it forms  $\text{C}_6\text{H}_4(\text{OH}).\text{NH.CO.CH}_2\text{Cl}$  (150°) (Asehan, *B.* 20, 1523). It reacts similarly with other amido-compounds.—3. Phosphuretted hydrogen forms chloro-acetyl-phosphide  $\text{CH}_2\text{Cl.CO.PH}_3$ , a white powder slowly decomposed by water into  $\text{PH}_3$  and chloro-acetic acid (Steiner, *B.* 8, 1178).

• Di-chloro-acetyl chloride  $\text{CHCl}_2\text{CO.Cl}$ . Mol. w. 147. (108°). Formed by the action of  $\text{PCl}_3$  on di-chloro-acetic acid (Otto & Beckurts, *B.* 14, 1618); or, together with the preceding, by boiling acetyl chloride with  $\text{PCl}_3$  (M.). Pungent, fuming liquid; decomposed at once by water. Successive treatment with  $\text{ZnMe}$ , and water forms (6 p.c. of) di-methyl-propyl-carbinol (B.).

Tri-chloro-acetyl chloride  $\text{CCl}_3\text{CO.Cl}$ . (117.9°) (Thorpe, *C. J.* 37, 189). S.G.  $\frac{1}{2}$  1.6504. C.E. (0°-10°) .001095; (0°-100°) .0012013. S.V. 125-51.

*Formation.*—1. From  $\text{PCl}_3$  and  $\text{CCl}_3\text{CO.H}$  (*Gal.* *C. R.* 76, 1019). The yield is very small. 2. By the protracted action of chlorine on ether, the operation being conducted towards the end in sunlight (Malaguti, *A. Ch.* [3] 16, 5). Also, by the distillation of penta-chloro-ethyl ether  $(\text{C}_2\text{Cl}_5)_2\text{O}$ , or of perchlorinated acetic ether  $\text{CCl}_3\text{CO}_2\text{C}_2\text{Cl}_5$ .—3. Together with  $\text{SO}_2$  from  $\text{C}_2\text{Cl}_4$  and  $\text{SO}_2$  at 150° (Prudhomme, *C. R.* 70, 1137). Also from  $\text{C}_2\text{Cl}_4$  and  $\text{SO}_2$ .

*Properties.*—Liquid; decomposed by water

into HCl and tri-chloro-acetic acid; alcohol gives tri-chloro-acetic ether.

*Reactions.*—1. Zinc methide followed by water gives the heptyl alcohol  $\text{CMe}_6\text{CM}_2\text{OH}$  (B.).—2.  $\text{PH}_3$  gives  $\text{CCl}_3\text{CO.PH}_3$  (Steiner, *B.* 8, 1178 Cloez, *A. Ch.* [3] 17, 309).—3. Tri-chloro-acetic acid forms the anhydride  $(\text{CCl}_3\text{CO})_2\text{O}$  (Anschütz *R.* 10, 4881).

**TRI-CHLORO-ACETYL CYANIDE**

$\text{CCl}_3\text{CO.CN}$ . Tri-chloro-pyruvonitrile. (118°) (H.); (122°) (C. a. A.). S.G.  $\frac{12}{13}$  1.559.

*Preparation.*—1. By adding AgCy slowly to cooled tri-chloro-acetyl bromide; the reaction being finished by heating on a water-bath (Hofferichter, *J. pr.* 128, 200).—2. By boiling tri-chloro-acetyl bromide with mercurous cyanide (Claisen & Antweiler, *B.* 13, 1935).

*Properties.*—Pungent, hygroscopic. Liquid smelling of prussic acid. Exposed to air it first becomes crystalline (forming a hydrate?) then deliquesces.

*Reactions.*—1. Water decomposes it into tri-chloro-acetic acid and prussic acid.—2. HCl (S.G. 1.16) at 50° converts it into tri-chloro-pyruvic acid  $\text{CCl}_3\text{CO.CO.H}$ .

Polymeride  $(\text{CCl}_3\text{CO.CN})_x$ . (140°). From AgCy and tri-chloro-acetyl bromide at 150° (H.). Dimetric tables (from ether-alcohol); insol. water.

**CHLORO-ACETYLENE**  $\text{CH}_3\text{CCl}$ . Formed by boiling  $\beta$ -di-chloro-acrylic acid  $\text{CH}_2\text{CHCl.CO.H}$  with baryta-water (Wallach, *A.* 203, 87). Gas, which explodes spontaneously, forming carbon and HCl. It is stable when diluted with hydrogen, and then, when passed into bromine, forms crystalline  $\text{C}_2\text{HClBr}_2$ . With ammoniacal cuprous chloride it forms an orange pp., and in ammoniacal silver nitrate a white pp. These pps. explode violently when heated.

**TRI-CHLORO-ACETYL IODIDE**  $\text{CCl}_3\text{CO.I}$ . (c. 180°). From tri-chloro-acetic acid and  $\text{PI}_3$  (*Gal.* *C. R.* 76, 1019).

**CHLORO-ACETYL-PROPIONIC ACID**

$\text{C}_3\text{H}_5\text{ClO}_2$ . Chloro-leucic acid.

Ethyl ether  $\text{A/Et}$  (225°-230°), S.G.  $\frac{11}{12}$  1.196. Prepared from  $\beta$ -acetyl-propionic ether  $\text{CH}_3\text{CO.CH}_2\text{CH}_2\text{CO}_2\text{Et}$  and chlorine. Colourless pungent liquid (Conrad & Guthzeit, *B.* 17, 2286).

**CHLORO-ACETYL-UREA**

$\text{NH}_2\text{CO.NH.CO.CH}_2\text{Cl}$ . From urea and chloro-acetyl chloride (Tommasi, *C. R.* 76, 640). Thin needles (from alcohol). Sl. sol. boiling water. With thio-urea it forms urea, HCl, and thiohydantoin.

Tri-chloro-acetyl-urea  $\text{NH}_2\text{CO.NH.CO.CCl}_3$ . [150°]. Formed by heating tri-chloro-acetyl chloride with urea (Tommasi & Meldola, *C. J.* 27, 404), or urea tri-chloro-acetate with  $\text{P}_2\text{O}_5$  (De Clermont, *C. R.* 78, 848). Needles or plates; insol. cold water.

**CHLORO-ACIDS** v. **CHLORO-COMPOUNDS.**

**$\alpha$ -CHLORO-ACRYLIC ACID**  $\text{C}_3\text{H}_3\text{ClO}_2$ , i.e.  $\text{CH}_2\text{=CCl.CO}_2\text{H}$ . (66°). (c. 178°).

*Formation.*—1. From  $\alpha$ -di-chloro-propionic acid  $\text{CH}_2\text{Cl.CHCl.CO}_2\text{H}$  by treatment with baryta or alcoholic KOH (Wergo, *A.* 170, 168; *B.* 10, 1499).—2. From  $\alpha$ -di-chloro-propionic acid  $\text{CH}_2\text{Cl.CCl}_2\text{CO}_2\text{H}$  and alcoholic KOH (Otto & Beckurts, *B.* 18, 239).

*Properties.*—Needles; v. sol. water, but may be extracted by ether. Fuming HCl at 100° forms  $\alpha$ -di-chloro-propionic acid.

**Salts.**—AgA': white crystalline pp.—KA'aq: needles.—BaA', 2aq: plates.

$\beta$ -Chloro-acrylic acid  $\text{CHCl:CH.CO}_2\text{H}$ . [84°].

**Formation.**—1. From ethyl tri-chloro-lactate (or from chloralide), zinc, and HCl in alcoholic solution (Pinner a. Bischoff, A. 179, 85; Wallach a. Hunsau, A. 193, 23).—2. By combination of propionic acid with HCl (Bandrowsky, B. 15, 2702).

**Preparation.**—From chloralide (50 g.), alcohol (150 g.), Zn (80 g.), HCl (80 g. of S.G. 1.24). The reaction is moderated by cooling, and after 24 hours more HCl (20 g.) and Zn (15 g.) are added. After 24 hours HCl (40 g.) is added. The alcohol and by-products are evaporated off and the remaining solution is extracted with benzene. The  $\beta$ -chloro-acrylic acid which is dissolved is subsequently distilled with steam. 1,000 g. of chloralide yield 12 g. of  $\beta$ -chloro-acrylic acid (Otto a. Fromme, A. 239, 264).

**Properties.**—Flexible laminae, n.s. sol. chloroform, v. sol. water, v. e. sol. benzene. Above 15° it separates from aqueous solution in oily drops. Aqueous HCl at 80° gives  $\text{CHCl}_2\text{CH}_2\text{CO}_2\text{H}$ . Combines with bromine (1 mol.).

**Salt.**—AgA'.

**Ethyl ether** EtA'. (144°).

$\alpha$ , $\beta$ -Di-chloro-acrylic acid  $\text{CHCl:CH.CO}_2\text{H}$ . [86°].

**Formation.**—1. By the action of KOH on mucochloric acid (Hill, Am. 3, 168; B. 12, 656). 2. By heating per-chloro-pyrocoll octo-chloride or di-chloro-maleimide with water at 130° (Ciamician a. Silber, B. 16, 2392).

**Properties.**—Monoclinic prisms;  $a:b:c = 1.865:1:3637$  (Hill a. Melville, P. Am. A. 17, 181). Volatilises rapidly in the air. V. e. sol. water, alcohol, and ether; v. sl. sol. benzene.

**Salts.**—AgA': slender needles.—KA': felted needles.—BaA', 3aq: trimetric plates. S. 6° at 18°.—CaA', 3aq: soluble needles.

$\beta$ -Di-chloro-acrylic acid  $\text{CCl}_2\text{:CH.CO}_2\text{H}$  (?) [77°] and [64°]. This acid may possibly be  $\alpha$ , $\alpha$ , $\beta$ -di-chloro-acrylic acid. Formed, together with  $\beta$ -chloro-acrylic acid, by reducing chloralide in alcoholic solution with Zn and HCl (Wallach, A. 193, 20; 203, 84). Slender needles or monoclinic prisms (from chloroform). Volatile in air; but cannot be distilled. After heating to 120° it melts at 64°, but, on keeping, the melting-point rises to 77°. V. sl. sol. water; v. sol. ether and chloroform. Does not combine directly with Br. Not attacked by water at 200°. Boiling baryta-water forms chloro-acetylene.

**Salts.**—KA'—AgA'—CaA', 2aq.—ZnA', 2aq. **Ethyl ether** EtA'. (174°). Saponified by cold KOHAq. Converted by treatment with Ag<sub>2</sub>O at 125° and saponification of the product by Ca(OH)<sub>2</sub> into malonic acid.

**Chloride**  $\text{CCl}_2\text{:CH.COCl}$ . (Above 145°). **Amide**  $\text{CCl}_2\text{:CH.CONH}_2$ . [113°]. Needles.

**Tri-chloro-acrylic acid**  $\text{CCl}_2\text{:CCl.CO}_2\text{H}$ . [76°]. S. 6 at 20°. From tri-chloro-bromo-propionic acid and cold baryta-water (Maßberg, Am. 9, 3). Trimetric prisms, sl. sol. water, m. spl. hot CS<sub>2</sub>, v. sol. alcohol, ether, and chloroform.

**Salts.**—KA': irregular plates, sl. sol. cold water.—AgA': slender needles, v. sl. sol. cold water.—CaA', 3aq: tufts of needles.—BaA', 8aq: branches of pearly needles.

**CHLORO-ALDEHYDE** v. **CHLORO-ACETIC ALDEHYDE**.

**CHLORO-ALDOXIM**  $\text{CH}_2\text{CH:NOCl}$ . Formed by mixing solutions of aldoxim and hypochlorous acid; the liquid which separates being washed with water and dried over CaCl<sub>2</sub>. Colourless liquid of powerful odour. Very unstable. Decomposes explosively on heating. Liberates iodine from HI (Möhlau a. Hoffmann, B. 20, 1507).

**CHLORO-ALIZARIN** v. **CHLORO-DI-OXY-ANTHRAQUINONE**.

**CHLORO-DIALLYL** v. **HEXYL CHLORIDE**.

**CHLORO-ALLYL ACETATE**.

$\text{CH}_2\text{:CCL.CH}_2\text{OAc}$ . (145°). Formed in small quantity, with other products, by the action of KOAc on di-chloro-propylene  $\text{CH}_2\text{:CCL.CH}_2\text{Cl}$  (Henry, B. 5, 454).

$\beta$ -Chloro-allyl acetate  $\text{CHCl:CH.CH}_2\text{OAc}$ . (a. 158°). From di-chloro-propylene  $\text{CHCl:CH.CH}_2\text{Cl}$  and KOAc (Martinoff, B. 8, 1318).

**CHLORO-ALLYL ALCOHOL**  $\text{C}_2\text{H}_4\text{CHO}$  i.e.  $\text{CH}_2\text{:CCL.CH.OH}$ . (136°) (H); (a. 138° i.v.) (R). S.G. <sup>25</sup> 1.164. Formed by boiling di-chloro-propylene  $\text{CH}_2\text{:CCL.CH}_2\text{Cl}$  (95°) with a dilute solution of K<sub>2</sub>CO<sub>3</sub> for some hours (Henry, C. R. 95, 849). Formed also by the action of dilute KOH or Ag<sub>2</sub>O upon  $\alpha$ -chloro-allyl iodide  $\text{CH}_2\text{:CCL.CH.I}$  (Van Romburgh, R. T. C. 1, 233).

Liquid with faint aromatic odour. Does not attack the skin. M. sol. water; gives  $\alpha$ -chloro-allyl acetate (145°) with Ac<sub>2</sub>O. When distilled with much water  $\alpha$ -chloro-allyl alcohol yields acetyl-carbinol  $\text{CH}_3\text{CO.CH}_2\text{OH}$ . HClO gives  $\text{CH}_2\text{Cl.CO.CH.OH}$ .

$\beta$ -chloro-allyl alcohol  $\text{CHCl:CH.CH}_2\text{OH}$ . (153° cor.) S.G. <sup>25</sup> 1.162. V.D. 3.3. Formed by treating  $\text{CHCl:CH.CH}_2\text{Cl}$  with aqueous KOH at 100° (Romburgh, Bl. [2] 36, 555). Pungent liquid, sl. sol. water. Mixes the skin. Combines with bromine.

**DI-CHLORO-DI-ALLYL-AMINE**  $\text{C}_4\text{H}_8\text{Cl}_2\text{N}$  i.e.  $(\text{CH}_2\text{:CCL.CH}_2)_2\text{NH}$  (?) (194°). From  $\alpha$ -tri-chloro-propane and alcoholic ammonia by heating for a few days at 140° (Engler, Bl. [2] 9, 134; A. 142, 72). Heavy oil, sl. sol. water.—B'HCl: deliquescent needles.—B'H.PiCl.

**Tetra-chloro-di-allyl-amine**  $\text{C}_4\text{H}_8\text{Cl}_4\text{N}$  i.e.  $(\text{CHCl:CCL.CH}_2)_2\text{NH}$ . From  $\text{CHCl:CCL.CH}_2\text{Cl}$  and alcoholic NH<sub>3</sub> at 120° (Fittig a. Pfeiffer, A. 135, 363). Alkaline liquid; cannot be distilled; volatile with steam; sl. sol. water.—B'HCl: needles.—E.H<sub>2</sub>CO.

**CHLORO-ALLYL-BROMIDE** v. **CHLORO-BROMO-PROPANE**.

**CHLORO-ALLYL-CHLORIDE** v. **DI-CHLORO-PROPANE**.

**CHLORO-ALLYLENE** v. **PROPARGYL CHLORIDE**.

**CHLORO-ALLYL ETHYL OXIDE** v. **ETHYL CHLORO-ALLYL OXIDE**.

**CHLORO-ALLYL IODIDE** v. **CHLORO-IODO-PROPANE**.

**CHLORO-ALLYL NITRATE**  $\text{C}_2\text{H}_4\text{ClNO}_2$  i.e.  $\text{CH}_2\text{:CCL.CH.NO}_2$ . (140°). From  $\alpha$ -chloro-allyl alcohol, H<sub>2</sub>SO<sub>4</sub>, and HNO<sub>3</sub> (Henry, C. R. 95, 849), or from  $\alpha$ -chloro- $\omega$ -iodo-propane  $\text{CH}_2\text{:CCL.CH}_2\text{I}$  and AgNO<sub>3</sub>. Oil (Romburgh, R. T. C. 1, 238).

**CHLORO-ALLYL THIO-CARBIMIDE**  $\text{C}_2\text{H}_4\text{CINS}$  i.e.  $\text{CH}_2\text{:CCL.CH.NCS}$ . (181°). From  $\text{CH}_2\text{:CCL.CH}_2\text{Cl}$  and potassium sulphocyanide

(Henry, C. R. 95, 849; *Bl.* [2] 89, 326). Liquid, smelling like mustard. Converted by ammonia into chloro-allyl thio-urea [91°].

**CHLORO-ALLYL TRIO-UREA**  $C_3H_5ClN_3S$  i.e.  $CH_2=CHCH_2NH_2 \cdot C_3N_3S$ . [91°]. Prepared as above (Henry, B. 5, 188).

#### CHLORO-AMIDES v. CHLORO-COMPOUNDS.

##### DI-CHLORO-AMIDO-ACETIC ETHER

$C_2H_2Cl_2NO_2$  i.e.  $CCl_2(NH_2)CO_2Et$ . *Di-chloro-glycocol.* Oxamethane chloride. From oxamic ether and  $PCl_5$  (Wallach, A. 184, 8). Unstable crystals, splitting off  $HCl$  and leaving  $NH_2 \cdot CCl_2CO_2Et$  and finally  $N \cdot C \cdot CO_2Et$ .

**Reactions.**—1. Water forms  $HCl$  and oxamic ether.—2. Butyl alcohol forms butyl oxamate; other alcohols and phenols act similarly.—3.  $POCl_3$  forms  $NH_2(POCl_2)CCl_2CO_2Et$  [130°], which may be crystallised from chloroform or ligroin, but is decomposed by water or heat.

**m-CHLORO-AMIDO-BENZENE (a)-SULPHONIC ACID**  $C_6H_4ClNSO_3$  i.e.  $C_6H_4(Cl)(NH_2)(SO_3H)$  [13:7]. Prepared by reducing *m*-chloro-nitrobenzene (a)-sulphonic acid with ferrous hydrate. Colourless soluble needles (Post a. Meyer, B. 14, 1607).

**m-Chloro-amido-benzene (b)-sulphonic acid**  $C_6H_4(Cl)(NH_2)(SO_3H)$  [1:3:7]. Prepared by reduction of *m*-chloro-nitro-benzene (b)-sulphonic acid with ferrous hydrate. Plates, sl. sol. water.

**Salts.**— $NaA'2aq$ : colourless needles.— $BaA'7aq$ : colourless thick needles, v. sol. water and alcohol (Post a. Meyer, B. 14, 1607).

**m-Chloro-amido-benzene (γ)-sulphonic acid**  $C_6H_4(Cl)(NH_2)(SO_3H)$  [1:3:7]. Prepared by sulphonation of *m*-chloro-aniline. Sparingly soluble crystals.

**Salts.**— $NaA'3aq$ : yellowish needles.— $NaA'2aq$ : colourless needles.— $BaA'3aq$ : small yellow needles, sol. alcohol.— $SrA'9aq$ : long colourless needles, sol. alcohol and water (Post a. Meyer, B. 14, 1607).

**Di-chloro-amido-benzene sulphonic acid**  $C_6H_2Cl_2(NH_2)(SO_3H)$ . From amido-benzene *m*-sulphonic acid and chlorine (Baskurts, A. 181, 212). Slender needles (containing 2aq): sl. sol. water.

**CHLORO-o-AMIDO-BENZOIC ACID**  $C_6H_4Cl(NH_2)(CO_2H)$  [1:4:5]. *Chloro-anthranilic acid*. [204°].

**Formation.**—From chloro-isatoic acid and conc.  $HCl$  (Drosch, J. pr. [2] 33, 50).

**Properties.**—Long white needles (from alcohol). V. sol. glacial acetic acid, acetone, and alcohol, sol. ether, benzene, and water containing  $HCl$ , m. sol. chloroform, sl. sol. water. Its solutions have a yellowish colour and exhibit violet fluorescence.

**Amide**  $C_6H_4Cl(NH_2)CO_2NH_2$  [172°]. By the action of hot  $NH_3$  upon chloro-isatoic acid. Flak. needles (from alcohol or from water). Sol. alcohol, acetone, and glacial acetic acid, less sol. chloroform, ether, benzene, and water.

**Chloro-o-amido-benzoic acid**  $C_6H_4Cl(NH_2)(CO_2H)$  [1:2:3].

**Chloro-anthranilic acid**. [148°]. From chloro-nitro-benzoic acid [186°] by reduction (Cunze a. Hübner, A. 135, 111; Hübner a. Weiss, B. 6, 175). Long needles, v. sl. sol. water.— $KA'2aq$ .— $AgA'$ .— $CaA'1\frac{1}{2}aq$ .— $BaA'1\frac{1}{2}aq$ .— $PbA'$ .

##### Chloro-m-amido-benzoic acid

$C_6H_4Cl(NH_2)CO_2H$  [1:2:4]. [212°]. Obtained by reducing the nitro-acid [180°] (Raveill, A. 222, 184). Formed also by boiling the diazo imide of benzoic acid with  $HCl$  (Griess, B. 19, 315). Reduced by sodium amalgam to *m*-amido-benzoic acid. **Salts.**— $PbA'$ .— $CuA'$ .— $HA'H \cdot SO_4$ .

##### Chloro-m-amido-benzoic acid

$C_6H_4Cl(NH_2)CO_2H$  [1:2:6]. [185°]. Formed together with the [1:3:4] isomeride by boiling the *m*-diazo imide of benzoic acid  $C_6H_4N_2CO_2H$  with  $HCl$  (Griess, B. 19, 315). White tables or small prisms. V. sol. hot water.

##### Chloro-m-amido-benzoic acid

$C_6H_4Cl(NH_2)CO_2H$  [1:4:6]. [212°]. From the nitro-acid [165°] by  $Sn$  and  $HCl$  (Wilkins a. Rack, A. 222, 198). Brownish needles (from water); v. sol. water or alcohol. Reduced by sodium amalgam to *m*-amido-benzoic acid.

**Salts.**— $PbA'1\frac{1}{2}aq$ .— $(A'Cu)_2O$ .— $HA'HCl$ .— $HA'H \cdot SO_4$ .— $HA'HNO_3$ .

##### o-Chloro-m-amido-benzoic acid

$C_6H_4Cl(NH_2)CO_2H$  [1:3:5]. [206°]. From  $C_6H_4Cl(NO_2)CO_2H$  [147°],  $Sn$ , and  $HCl$  (Hübner, A. 222, 90). Long needles; v. sol. alcohol or ether, sl. sol. water.

**Salts.**— $BaA'4aq$ .— $AgA'$ .— $CuA'$ .

##### Di-chloro-o-amido-benzoic acid

$C_6H_2Cl_2(NH_2)CO_2H$  [1:2:4:5]. *Di-chloro-anthranilic acid*. [222°-224°]. Formed by boiling di-chloro-isatoic acid with conc.  $HCl$  (Dorsch, J. pr. [2] 33, 52). Needles. V. sol. ordinary solvents, except water.

**Amide**  $C_6H_2Cl_2(NH_2)CO_2NH_2$  [284°]. From di-chloro-isatoic acid and aqueous ammonia. Short thick needles (from alcohol-acetone). Sl. sol. all solvents.

##### Tri-chloro-amido-benzoic acid

$C_6HCl_3(NH_2)(CO_2H)$  [1:3:5:2:4]. [210°]. From tri-chloro-nitro-benzoic acid, tin, and  $HCl$  (Beilstein a. Kuhlberg, A. 152, 240). Small slender needles (from water); sl. sol. boiling water. Does not unite with acids.— $BaA'3aq$ .

##### Tetra-chloro-amido-benzoic acid

$C_6Cl_4(NH_2)CO_2H$  [1:2:3:4:5:6]. *Tetra-chloro-anthranilic acid*. Obtained by reduction of tetra-chloro-nitro-benzoic acid with tin and  $HCl$ . Colourless amorphous solid. V. sol. alcohol, nearly insol. water (Tust, B. 20, 2441).

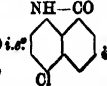

##### DI-CHLORO-o-AMIDO-BENZOIC ALDEHYDE

$C_6H_2Cl_2(NH_2)CHO$ . [78°]. Obtained by reduction of di-chloro-nitro-benzaldehyde with  $FeSO_4$  and  $NH_3$  (Gnehm, B. 17, 754). Yellow needles. Sl. sol. water.

##### CHLORO-AMIDO-NAPHTHALENE v. CHLORO-NAPHTHYLAMINE.

**Chloro-di-amido-naphthalene v. CHLORO-NAPHTHYLENE-DIAMINE.**

##### CHLORO-AMIDO-(a)-NAPHTHOIC LACTAM

$C_{10}H_6ClNO$  i.e.  [270°]. *Chloro-amido-*

*(a)-naphthoid. Chloro-naphthostyryl.* Formed by reduction of chloro-nitro-(a)-naphthoic acid [225°] with  $FeSO_4$  and  $NH_3$ . Yellow needles (from alcohol) (Ekstrand, B. 18, 2881).

## Di-chloro-amido-naphthoic lactam

Formed by chlorination of the lactam of amido-( $\alpha$ )-naphthoic acid. Also by heating nitro-( $\alpha$ )-naphthoic acid [215°] with excess of fuming HCl for two hours at 140°–150°. Yellow needles (from acetic acid). Sl. sol. alcohol (Ekstrand, B. 13, 1132).

CHLORO- $\alpha$ -AMIDO-PHENOL

$\text{C}_6\text{H}_4\text{Cl}(\text{NH}_2)(\text{OH})$  [1:3:4]. From chloro- $\alpha$ -nitro-phenol, tin, and HCl (Faust & Saame, A. Suppl. 7, 193).—B'HCl: laminae (from water).

*Methyl ether*  $\text{C}_6\text{H}_3\text{Cl}(\text{NH}_2)(\text{OMe})$ . Chloro-anisidine [52°]. (260°). From the nitro-compound. White needles or prisms. Sol. alcohol, ether, and benzene. Salts.—B'HCl: colourless soluble needles.— $\text{B}_2\text{H}_2\text{Cl}_2\text{PtCl}_6$ : soluble yellow needles.

*Picrate*  $\text{B}'\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$ : [about 200°]; yellow needles, sol. alcohol and ether, sl. sol. water.

*Acetyl derivative* [150°]. (326°), glistening plates (Herold, B. 15, 1685).

Chloro- $p$ -amido-phenol  $\text{C}_6\text{H}_4\text{Cl}(\text{NH}_2)(\text{OH})$  [1:3:6]. [153°]. From  $p$ -nitro-phenol by treatment with  $\text{KClO}_4$  and HCl and reducing the product with tin and HCl (Kollrepp, A. 234, 6). Unstable needles, v. sol. alcohol and ether. Bleaching powder and HCl give chloro-quinone chlorimide  $\text{C}_6\text{H}_3\text{Cl}(\text{NClO})$ . Salts.—B'HCl: trimetric plates.— $\text{B}'\text{H}_2\text{SO}_4$  2aq: scales.— $\text{B}'\text{H}_2\text{C}_2\text{O}_4$  3½aq: needles.—Tartrate  $\text{B}'\text{C}_6\text{H}_3\text{O}_4$ : monoclinic crystals, insol. water.

Di-chloro- $\alpha$ -amido-phenol

$\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)(\text{OH})$  [1:3:5:6]. From di-chloro-nitro-phenol [121°] by tin and HCl (Fischer, A. Suppl. 7, 189). Unstable scales; reduces  $\text{AgNO}_3$ , forming a mirror.—B'HCl: ppd. by HCl from solution.— $\text{B}'\text{H}_2\text{SO}_4$ .

Di-chloro- $p$ -amido-phenol

$\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)(\text{OH})$  [1:3:5:2]. [167°]. From di-chloro-nitro-phenol [125°] by tin and HCl (Kollrepp, A. 234, 10; Seifert, A. Suppl. 7, 202). Needles (from water); may be sublimed. Oxidation gives di-chloro-quinone. HCl and bleaching powder give di-chloro-quinonimide.—B'HCl.—B'HB: hexagonal plates; v. sl. sol. cold water.— $\text{B}'\text{H}_2\text{SO}_4$  3aq: needles.— $\text{B}'\text{HNO}_3$ : [110°]; plates.— $\text{B}'\text{H}_2\text{C}_2\text{O}_4$ : needles.

Di-chloro- $p$ -amido-phenol  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)(\text{OH})$ . [173°]. Formed by passing HCl into an ethereal solution of  $p$ -nitroso-phenol (Jaeger, B. 8, 895). Needles; may be sublimed. Is perhaps identical with the preceding.

*Methyl ether*  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)(\text{OMe})$ . [72°]. Formed by passing HCl into a solution of  $p$ -nitroso-phenol in  $\text{MeOH}$  (J.). Long slender needles (from dilute alcohol).

*Ethyl ether*.  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)(\text{OEt})$ . [46°]. (275°).

Tri-chloro- $m$ -amido-phenol

$\text{C}_6\text{HCl}_3(\text{NH}_2)(\text{OH})$  [1:3:5:6:2]. [96°]. Formed from tri-chloro-nitro-phenol  $\text{C}_6\text{HCl}_3(\text{NO}_2)(\text{OH})$  by reduction with tin and HCl (Dacomo, B. 13, 1166). Colourless silky needles. V. sol. alcohol, ether, benzene, and hot water;  $\text{Fe}_2\text{Cl}_6$  gives a splendid violet-red colouration.

Tri-chloro- $p$ -amido-phenol

$\text{C}_6\text{HCl}_3(\text{NH}_2)(\text{OH})$ . [159°].

**Formation.**—1. From  $p$ -amido-phenol by chlorination; the by-products are tri- and tetra-chloro-hydro-quinone (Lampert, J. pr. [2] 33, 371).—2. From quinone chloro-imide and conc. HCl (Hirsch, B. 11, 1931; 13, 1904).

**Preparation.**—By passing chlorine gas into conc. HCl in which  $p$ -amido-phenol hydrochloride is suspended. The reaction is ended as soon as a portion of the crystalline product dissolves completely in water and gives, on adding bleaching powder solution, flocculent tri-chloro-quinone chloro-imide, while the supernatant liquid shows no turbidity (which would be due to oily di-chloro-quinone chloro-imide). The base is precipitated by  $\text{Na}_2\text{CO}_3$  (R. Schmitt a. M. Andresen, J. pr. [2] 24, 426).

**Properties.**—Glistening needles (from alcohol). Is a weak base, its hydrochloride being decomposed by boiling with water (Hirsch, B. 13, 1903).

**Reactions.**—1.  $\text{NaOH}$  solution and air convert it into tri-chloro-quinone.—2. By diazo-reaction it yields tri-chloro-phenol [54°].—3. Bleaching powder and HCl give tri-chloro-quinone chlorimide. Salts.—B'HCl.— $\text{B}'\text{H}_2\text{SO}_4$ : small needles.

CHLORO- $\alpha$ -AMIDO-PHENOL- $\nu$ -SULPHONIC ACID  $\text{C}_6\text{H}_3\text{Cl}(\text{OH})(\text{NH}_2\text{SO}_3\text{H})$  [1:2:5]. Formed by adding conc. aqueous  $\text{NaHSO}_3$  to mono- or di-chloro-quinone chlorimide, air being excluded (Kollrepp, A. 234, 21). Anhydrous needles (from hot water), which change under water to trimetric prisms (containing 24aq). Sl. sol. cold water, insol. ether. Reduces boiling Fehling's solution. Gives a silver mirror. Converted by nitrous acid into the diazo-acid  $\text{C}_6\text{H}_3\text{Cl}_2\text{N}_2\text{SO}_3$  3aq which crystallises in prisms. Salts.— $\text{ZnA}_2$ : trimetric prisms.— $\text{NiA}_2$ .— $\text{CuA}_2$ : minute yellowish-brown needles, insol. cold water.

CHLORO- $\alpha$ -AMIDO-DIPHENYL  $\text{C}_{12}\text{H}_9\text{ClN}$  i.e.  $\text{C}_6\text{H}_4\text{Cl}(\text{NH}_2)$ . [48°]. Formed by reducing  $\alpha$ -nitro-diphenyl with tin and HCl (Hübner a. Osten, A. 209, 349). Long needles (from dilute alcohol); sl. sol. water, v. sol. alcohol and ether. Its salts are partially decomposed by water.—B'HCl: laminae.— $\text{B}'\text{H}_2\text{PtCl}_6$ : orange tables.— $\text{B}'\text{HNO}_3$ .— $\text{B}'\text{H}_2\text{SO}_4$ .

## Chloro-di-amido-diphenyl

$\text{C}_6\text{H}_4(\text{NH}_2)_2\text{C}_6\text{H}_4\text{ClN}$ . Formed by allowing an alcoholic solution of benzene-azo- $p$ -chloro-benzene mixed with  $\text{SnCl}_4$  and a couple of drops of  $\text{H}_2\text{SO}_4$  to stand in the cold. The base was not isolated in a pure state. The hydrochloride  $\text{B}'\text{H}_2\text{Cl}$  forms white concentric needles (Menthia a. Haumann, B. 19, 2970).

## Di-chloro-di-amido-diphenyl

$\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)_2\text{C}_6\text{H}_4\text{Cl}(\text{NH}_2)$ . [300°]. Formed by treating  $p$ -chloro-benzene-azo- $p$ -chloro-benzene  $\text{C}_6\text{H}_3\text{Cl}_2\text{N}_2\text{C}_6\text{H}_4\text{Cl}$  with  $\text{SnCl}_4$  (Schultz, B. 17, 464). Glistening laminae.— $\text{B}'\text{H}_2\text{SO}_4$ .

CHLORO-DI-AMIDO-DI-PHENYL-AMINE- $\alpha$ -CARBOXYLIC ACID

$\text{C}_6\text{H}_3\text{Cl}(\text{NH}_2)_2\text{NH}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$  [3. 240°]. Formed by reduction of chloro-di-nitro-di-phenyl-amine- $\alpha$ -carboxylic acid with tin and HCl (Jourdan, B. 18, 1455). Colourless felted needles. Sl. sol. hot water and ether, nearly insol. benzene and ligroin.  $\text{Fe}_2\text{Cl}_6$  gives a brownish-violet colouration.

DI-CHLORO-TRI-AMIDO-TRI-PHENYL-CARBINOL  $\text{C}_{18}\text{H}_{15}\text{Cl}_2\text{N}_3\text{O}$  i.e.  $\text{C}(\text{OH})(\text{C}_6\text{H}_4\text{Cl}_2\text{NH}_2)_3(\text{C}_6\text{H}_5\text{NH}_2)$ . Di-chloro-para-

## CHLORO-AMYL-ALCOHOL.

**Rosaniline.** Formed by heating *p*-toluidine (21 g.), *o*-chloro-toluidine (50 g.), and aqueous arsenic acid (106 g. of 75 p.c.) at 190° (Heumann a. Heidberg, *B.* 19, 1989). Lustrous green mass. Dyes much bluer shade than ordinary rosaniline.

**CHLORO-AMIDO-PHENYLENE MERCAPTAN**  $C_6H_4ClNS$ , i.e.  $C_6H_4Cl(NH_2)(SH)$ , [3:5:2:1]. From the chloride of *p*-chloro-nitro-benzene disulphinic acid by tin and HCl (Allert, *B.* 14, 1486). Does not react with formic acid.

**CHLORO-AMIDO-PHENYL-ETHYLENE** *v.* **CHLORO-AMIDO-STYRENE.**

**CHLORO-AMIDO-PHENYL GLYOXYLIC ACID** *v.* **ISATIN.**

**CHLORO-AMIDO-PHENYL MERCAPTAN**  $C_6H_4Cl(NH_2)(SH)$ , [130°]. From *m*-chloro-nitro-benzene sulphonic acid, tin, and HCl (Allert, *B.* 14, 1485).—*D*-HCl.

**Exo-CHLORO-*exo*-AMIDO-PROPYL-PYRIDINE**

**CATECHIN Mono-methyl ether**  $C_6H_3Cl_2C_2H_4(NH_2)(OMe)(OH)$  [1:5:3:4]. [97°]. From nitro-eugenol  $C_6H_3C_2H_4(NO_2)(OMe)(OH)$  by tin and HCl (Weselsky a. Benedikt, *M.* 3, 389). Pearly plates (from alcohol).—*B*-HCl aq.

**TRI-CHLORO-AMIDO-PYRIDINE**  $C_4H_3Cl_3N$ , probably  $N \begin{smallmatrix} \text{CCl} \cdot \text{CH} \\ \text{CCl} \cdot \text{CCl} \end{smallmatrix} > C \cdot NH_2$ . [158°]. Formed

in small quantity, together with di-chloro-di-oxy-amido-pyridine, tri-chloro-oxy-amido-pyridine, and tetra-chloro-amido-pyridine, by heating glutazine with  $PCl_5$  (6 to 7 pts.). Long felted colourless needles. Sublimable. *V.* sol. alcohol, *sl.* sol. hot water. Dissolves in aqueous acids, but not in alkalis. Its *bromo-derivative* forms flat colourless needles [223°] (Stokes a. Pechmann, *B.* 19, 2710; *Am.* 8, 392).

**Tetra-chloro-amido-pyridine**  $C_4H_2Cl_4N$ , probably  $N \begin{smallmatrix} \text{CCl} \cdot \text{CCl} \\ \text{CCl} \cdot \text{CCl} \end{smallmatrix} > C \cdot NH_2$ . [212°]. Formed, together with an equal quantity of tri-chloro-oxy-amido-pyridine, and small quantities of di-chloro-di-oxy-amido-pyridine and tri-chloro-amido-pyridine, by heating glutazine with  $PCl_5$  (6 to 7 mols.). Thin colourless plates or cubical crystals. Sublimable. *Sol.* hot benzene, *m.* sol. hot alcohol, *sl.* sol. cold alcohol, *insol.* water. It does not dissolve in aqueous alkalis, and only slightly in conc. HCl. Alcoholic NaOEt forms  $C_4H_2N_2Cl_4(OEt)_2$  (83°) and  $C_4H_2N_2Cl_4(OEt)_2$ , [98°] (Stokes a. Pechmann, *B.* 19, 2710; *Am.* 8, 396).

**DI-CHLORO-DI-AMIDO-QUINONE**  $C_6Cl_2(NH_2)_2O_2$ . **Chloranilamide.** Prepared by adding crystallised tetra-chloro-quinone rubbed up with alcohol to a boiling alcoholic solution of ammonia; after the tetra-chloro-quinone has dissolved, the compound separates in brown needles (Laurent, *Rev. Scient.* 19, 141; *A.* 52, 347; Knapp a. Schultz, *A.* 210, 1857). Dark lustrous needles, *insol.* water, alcohol, and ether, readily sublimed. Its solution in alcoholic KOH is violet. Boiling  $SnCl_4$  forms unstable  $C_6Cl_2(NH_2)_2(OH)_2$ . Fuming  $HNO_3$  forms chloropiricin and oxalic acid.

***o*-CHLORO-*o*-AMIDO-STYRENE**  $C_6H_3Cl_2(NH_2)(OH)$ . ***o*-Amido-phenyl-*o*-chloro-styrene.** White concentric prisms. *V.* sol. alcohol and ether, *v.* *sl.* sol. cold water. Formed by reduction of *o*-chloro-*o*-nitro-styrene with tin and HCl. By heating with sodium ethylate at

about 170° it gives indole.—*B*-HCl: colourless needles, *v.* sol. water and alcohol (Lipp, *B.* 1 1071).

**CHLORO-AMIDO-SULPHO-BENZOIC ACID**  $C_6H_4ClNSO_3$ , i.e.  $C_6H_4Cl(NH_2)(SO_3H)(CO_2H)$  [1:2:3:3]. From chloro-*o*-amido-benzoic acid an fuming  $H_2SO_4$  (Cunze a. Hübner, *A.* 135, 113).—*BaA*': clumps.

**CHLORO-AMIDO-THYMOL**

$C_6HClMePr(NH_2)(OH)$ . [101°] (*A.*); [103°] (*S.*)

**Preparation.**—1. By pouring 4 vols. conc. HC upon thymo-quinone-chloro-imide (*q.v.*); the liquid begins to boil and yellow crystals separate. The liquid is shaken with ether, and the ether containing chloro-thymo-quinones, is decanted, the residue, in which the chloro-amido-thymo-hydrochloride is suspended, is then filtered and decomposed by  $Na_2CO_3$ . It dissolves in excess of  $Na_2CO_3$  giving the solution a green colour. This must be avoided.—2. In a similar way from chloro-thymo-quinone-chloro-imide (*q.v.*). 3. From thymo-quinone-oxim (nitroso-thymol) and cold fuming  $HCl$  aq. (Sutkowski, *B.* 19, 2315).

**Properties.**—Glittering crystals (from water). *V.* sol. alcohol and ether (Andresen, *J. pr.* [2] 23, 175). Bleaching-powder forms chloro-thymo-quinone chlorimide. Heating with chloranil in  $HOAc$  produces a red dye  $C_{10}H_7Cl_2N_2O_2$  [232°].

**CHLORO-AMIDO-TOLUENE** *v.* **CHLORO-TOLUIDINE.**

**CHLORO-AMIDO-XYLENE** *v.* **CHLORO-XYLIDINE.**

***exo*-Chloro-amido-*o*-xylene**

$ClCH_2C_6H_3CH_2NH_2$ . Formed by the action of  $HCl$  aq. at 200° on its phthalyl derivative (Strassmann, *B.* 21, 581).

**Phthalyl derivative**

$[1:2]ClCH_2C_6H_3CH_2N(CO)C_6H_4[1:2]$ . ***Exo*-chloro-xylene-phthalimide.** [140°]. Formed by the action of *exo*-di-chloro-*o*-xylene (1 mol.) on potassium phthalimide (1 mol.) at 200° (Strassmann, *B.* 21, 580). Prisms (from alcohol). Heated with  $HCl$  aq. to 200° it is converted into phthalic acid and *exo*-chloro-amido-xylene.

***o*-CHLORO-ISOAMYL ACETATE**

$C_6H_5CHClOAc$ . (118°–128°). *S.G.* 1.987. From isovaleric aldehyde and  $AcCl$  (Maxwell Simpson, *Pr.* 27, 120). Liquid, slowly decomposed by water.

**Tri-chloro-*sec*-amyl-acetate**

$CHMe(C_2H_5Cl)_3OAc$ . (129°–134°) at 25 mm.; (227°) at 726 mm. *S.G.* 1.305. From methyl-tri-chloro-propyl carbinol and  $AcCl$  (Garzarolli-Thurnlackh, *A.* 223, 151).

**CHLORO-AMYL-ALCOHOL**  $C_6H_5ClO$  i.e.  $C_6H_5Cl(OH)$ . ***Amylene glycol chlorhydrin.*** (155°). From crude amylenes and aqueous  $HClO$  (Carius, *A.* 126, 199; Eliakoff, *J. R.* 14, 380). *V.* sol. water. Decomposed by potash with formation of amylenes oxide.  $Na_2SO_3$  forms oxy-pentane sulphonic acid (*q.v.*).

**Tri-chloro-amyl alcohol**  $C_6H_5Cl_3O$  i.e.  $CH_2CHCl.CCl_2CHMe.OH$ . [50°–5°]. (109°) at 20 mm.; (124°) at 41 mm. From tri-chloro-butyric aldehyde and  $ZnMe_2$  in ether, followed by water (Garzarolli-Thurnlackh, *A.* 223, 149).

**Properties.**—Silky needles grouped in rosettes (from ether). Smells of camphor. Volatile with steam. Faintly soluble in water, *v.* sol. alcohol and ether. Carbonised by conc.  $H_2SO_4$ .

**Reactions.**—1. Warm fuming  $\text{HNO}_3$  gives  $\text{CO}_2$  and tri-chloro-butyric acid.—2.  $\text{H}_2\text{SO}_4$  and  $\text{K}_2\text{Cr}_2\text{O}_7$  give the ketone  $\text{C}_6\text{H}_4\text{Cl}_3\text{CO.Me}$  (191°–193°).—3. Finely divided iron and acetic acid reduce it to chloro-pentenyl alcohol (*q. v.*).

**CHLORO-AMYL-ANTHRACENE**  $\text{C}_{18}\text{H}_{11}\text{Cl}$  or  $\text{C}_6\text{H}_4\text{Cl} \cdot \text{C}(\text{C}_6\text{H}_4) > \text{C}_6\text{H}_4$ . [71°]. Prepared by chlorination of amyl-anthracene in  $\text{CHCl}_3$ . Light yellow needles with blue fluorescence.

**Picric acid compound:** red needles (Liebmann & Tobias, *B.* 14, 797).

**$\alpha$ -CHLORO- $n$ -AMYLENE**  $\text{C}_6\text{H}_4\text{Cl}$  i.e.  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CClCH}_2$ . (96°). S.G. 2 1.872. From amylene chloride and alcoholic KOH (Bruylants, *B.* 8, 411).

**$\alpha$ -Chloro-iso-amylene**  $(\text{CH}_3)_2\text{CH.CH.CHCl}$ . (86°). From isoamylidenedichloride  $\text{PrCH}_2\text{CHCl}_2$  and alcoholic KOH (*B.*).

**Chloro-amylene**  $\text{C}_6\text{H}_4\text{Cl}$ . **Valerylene hydrochloride.** (100°). From valerylene and fuming aqueous HCl at 100° (Reboul, *Z.* 1867, 173).

**Isoprene hydrochloride**  $\text{C}_6\text{H}_4\text{Cl}$ . (85°–91°). S.G. 2 1.885 (Bouchardat, *C. R.* 89, 1317).

**Di-chloro-amylene**  $\text{CH}_2\text{CH}_2\text{CClCHClCH}_2$ . (142°–144°) at 736 mm. From chloro-pentenyl alcohol  $\text{C}_6\text{H}_4\text{Cl.CH(OH).CH}_2$  by  $\text{PCl}_5$ . Partly converted by boiling water into chloro-pentenyl alcohol (Garzaroli-Thurnlackh, *A.* 223, 160).

**Tri-chloro-amylene**  $\text{C}_6\text{H}_3\text{Cl}_3$ . (146°). From tri-chloro-hexaol aldehyde and conc. KOH (Pinner, *A.* 179, 35; *B.* 10, 1052). Gives with bromine  $\text{C}_6\text{H}_3\text{Cl}_2\text{Br}$ , (230°–240°).

**Tri-chloro-amylene**  $\text{C}_6\text{H}_3\text{Cl}_3$ . (200°). From tetra-chloro-pentane (240°) and alcoholic KOH (Bauer, *C. R.* 51, 572).

**CHLORO-AMYLENE DI-CARBAMIC ETHER**  $\text{C}_{11}\text{H}_{12}\text{ClN}_2\text{O}_2$  i.e.  $\text{C}_6\text{H}_4\text{Cl}(\text{NH.CO.OEt})_2$ . (130°). From isovaleric aldehyde, carbamic ether, and HCl (Bischoff, *B.* 7, 633).

**CHLORO-DI-AMYL SULPHONE**  $\text{C}_6\text{H}_4\text{Cl}_2\text{SO}_2$ . (330°). Formed together with di-chloro-di-amyl sulphone  $(\text{C}_6\text{H}_4\text{Cl})_2\text{SO}_2$  by treating di-amyl sulphone with  $\text{ICl}_3$  at 130° (Spring & Winssinger, *B.* [2] 41, 307).

**CHLORO-ANETHOL**  $\text{C}_6\text{H}_4\text{ClO}$ . (6°). (258°) (Ladenburg); (229°) (Landolph). S.G. 2 1.115 (Lad.); 2 1.191 (Lan.). Prepared by the action of  $\text{PCl}_5$  on anethol (Ladenburg, *A. Suppl.* 8, 90). By treatment with KOH it gives a mixture of two liquids, the first of which,  $\text{C}_6\text{H}_4\text{O}$ , boils at (268°–270°), and the second can be converted into the first by more prolonged action of the KOH (Landolph, *B.* 13, 148).

**CHLORO-ANGELIC ACID**  $\text{CH}_2\text{Cl.CCl.CH.CH}_2\text{CO.OH}$  (?) (104°). The ethyl ether is formed by treating di-chloro-angelic acid in alcoholic solution with zinc and HCl (Pinner & Klein, *B.* 11, 1498).

**Ethyl ether EtA.** Liquid. Isomeride of **CHLORO-TOLIC ACID**. Di-chloro-angelic acid  $\text{C}_6\text{H}_4\text{Cl}_2$  i.e.  $\text{CH}_2\text{Cl.CCl.CH.CHClCO.OH}$  (?). From chloro-oxy-angelic acid and  $\text{PCl}_5$  (Pinner & Klein, *B.* 11, 1498). Oil.

**CHLORANILIC ACID** or **p-Di-chloro-p-di-oxy-quinone**.

**$\alpha$ -CHLORO-ANILINE**  $\text{C}_6\text{H}_4\text{ClN}$  i.e.  $\text{C}_6\text{H}_3\text{Cl}(\text{NH}_2)$  [1:2]. Mol. w. 127½. (207° i. v.). S.G. 2 1.2533.

**Formation.**—By reduction of  $\alpha$ -chloro-nitro-benzene. May be separated from  $p$ -chloro-aniline by distilling the sulphates with steam, that of  $\alpha$ -chloro-aniline being decomposed (Beilstein & Kurbatoff, *A.* 176, 27).

**Salts.**— $\text{B}^+\text{HCl}$ : trimetric plates: S. 1C at 15°.— $\text{B}^+\text{HNO}_2$ : S. 10 at 13.5°.—Picrate: v. sl. sol. cold water; sl. sol. alcohol.

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{Cl}(\text{NHAc})$ . [88°]. Long flat needles (from dilute HOAc) (Beilstein & Kurbatoff, *A.* 182, 100).

**m-Chloro-aniline**  $\text{C}_6\text{H}_4\text{Cl}(\text{NH}_2)$  [1:3]. (230° i. v.). S.G. 2 1.243. From  $m$ -chloro-nitro-benzene (B. & K.). Its salts are hardly decomposed by boiling water.— $\text{B}^+\text{HCl}$ — $\text{B}^+\text{HBr}$ : long red needles (Staedel, *B.* 16, 28).— $\text{B}^+\text{HNO}_2$ .— $\text{B}^+\text{H}_2\text{SO}_4$ : sl. sol. cold water.

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{Cl}(\text{NHAc})$ . [73°]. Needles.

**p-Chloro-aniline**  $\text{C}_6\text{H}_4\text{Cl}(\text{NH}_2)$  [1:4]. [70°]. (231° i. v.).

**Formation.**—1. By distilling chloro-isatin with KOH (Hofmann, *A.* 53, 17)—2. By reducing  $p$ -chloro-nitro-benzene with  $\text{SnCl}_2$ .—3. From its acetyl derivative obtained by chlorinating acetanilide (Mills, *P. M.* 49, 21).

**Properties.**—Trimetric prisms. Is a strong base.

**Salts.**— $\text{B}^+\text{HCl}$ .— $\text{B}^+\text{H}_2\text{P}_2\text{O}_7$ .— $\text{B}^+\text{HNO}_2$ : laminae, S. 6–7 at 12.5°.— $\text{B}^+\text{H}_2\text{SO}_4$ : sl. sol. cold water.— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ ,  $\frac{1}{2}\text{aq}$ .

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{Cl}(\text{NHAc})$ . [173°]. Thick needles (from dilute HOAc).

**c-Di-chloro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)$  [1:2:3]. Mol. w. 162. [24°]. (252°). From nitro-benzene by chlorination, in presence of  $\text{SnCl}_4$  and reduction (Beilstein & Kurbatoff, *A.* 196, 214; *B.* 11, 1860). Needles (from ligroin).

**Acetyl derivative**  $\text{C}_6\text{H}_2\text{Cl}_2(\text{NHAc})$ . [157°].

**c-Di-chloro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)$  [3:1:2]. [39°]. From di-chloro-nitro-benzene [71°] (B. & K.). Needles, v. sl. ligroin.

**Acetyl derivative**  $\text{C}_6\text{H}_2\text{Cl}_2(\text{NHAc})$ . [175°].

**s-Di-chloro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)$  [1:3:5]. [50°–5°]. (260° i. v.). From s-di-chloro-nitro-benzene (Witt, *B.* 8, 145; B. & K.; Langer, *A.* 215, 120).

**Acetyl derivative**  $\text{C}_6\text{H}_2\text{Cl}_2(\text{NHAc})$ . [187°].

**Di-chloro-aniline**  $\text{C}_6\text{H}_4\text{Cl}_2(\text{NH}_2)$  [1:4:2]. [50°]. (251°). From di-chloro-nitro-benzene [55°] (Jungfleisch, *A. Ch.* [4] 15, 252; B. & K.). (251°).

Formed also by chlorinating  $m$ -chloro-aniline and by heating nitro-benzene with fuming HCl at 245° (Baumhauer, *A. Suppl.* 7, 209). CrO, gives di-chloro-quinone.

**Acetyl derivative**  $\text{C}_6\text{H}_2\text{Cl}_2(\text{NHAc})$ . [132°].

**Di-chloro-aniline**  $\text{C}_6\text{H}_4\text{Cl}_2(\text{NH}_2)$  [1:3:4]. [63°]. (245°). From acetanilide (1 mol.) and chlorine (2 mols.). Obtained also by chlorinating  $o$ - or  $p$ -chloro-aniline (Griess, *A.* 181, 266; Beilstein, *A.* 182, 95; Witt, *B.* 7, 1602).— $\text{B}^+\text{HCl}$ .— $\text{B}^+\text{H}_2\text{P}_2\text{O}_7$ .

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NHAc})$ . [148°].

**Di-chloro-aniline**  $\text{C}_6\text{H}_4\text{Cl}_2(\text{NH}_2)$  [1:2:4]. [71°–5°]. (272°). From di-chloro-nitro-benzene [43°], or by chlorinating  $m$ -chloro-aniline (B. & K.). Long needles; strong base.

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NHAc})$ . [120°–5°].

**c-Tri-chloro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_3(\text{NH}_2)$  [1:2:3:4]. Mol. w. 196.5. [87°–5°]. (292° i. v.).

**Formation.**—1. From its acetyl derivative.  
2. By reducing  $C_6H_4(NO_2)Cl$  [1:2:3:4].

**Acetyl derivative**  $C_6H_4(NHAc)Cl$ . [122°]. When chlorine is passed into a solution of acetyl *m*-chloro-aniline in strong (90 p.c.) acetic acid, two acetyl-trichloro-anilines are formed; one of these,  $C_6H_2Cl_3(NHAc)$  [1:2:4:5] [185°] is hardly soluble in dilute (50 p.c.) acetic acid, the other [1:2:3:4] is soluble (Beilstein a. Kurbatoff, A. 192, 234).

**Tri-chloro-aniline**  $C_6H_2Cl_3(NH_2)$  [1:3:5:6]. [77-75°]. (262° i. V.). From aniline, *p*-chloro-aniline, or (1, 3, 4)-di-chloro-aniline in glacial acetic acid by chlorine (Hofmann, A. 53, 35; Beilstein a. Kurbatoff, B. 11, 1802; Langer, A. 215, 114). Also from aniline and  $SO_2Cl_2$  (Venghoff, J. pr. [2] 16, 449). Long needles (from ligroin).

**Acetyl derivative**  $C_6H_2Cl_3(NH_2)$ . [204°]. **Tri-chloro-aniline**  $C_6H_2Cl_3(NH_2)$  [1:2:4:5]. [96°]. From  $C_6H_4(NO_2)Cl$  [58°] (Lesimple, A. 137, 125; Beilstein a. Kurbatoff, A. 192, 231). Obtained also by chlorinating (2, 5, 1)- or (3, 4, 1)-di-chloro-aniline, or *m*-chloro-aniline. Needles (from ligroin).

**Acetyl derivative**  $C_6H_2Cl_3(NHAc)$ . [185°].

**Tetra-chloro-aniline**  $C_6HCl_4(NH_2)$  [1:2:3:5:6]. [83°]. Formed by chlorinating *m*-chloro-aniline (B. a. K.). Gives, by eliminating  $NH_3$ , tetra-chloro-benzene [51°].

**Acetyl derivative**  $C_6HCl_4(NHAc)$ . [174°]. **Tetra-chloro-aniline**  $C_6HCl_4(NH_2)$  [1:2:4:5:6]. [96°]. Prepared by reducing *s*-tetra-chloro-nitro-benzene (Lesimple, Z. 1868, 227).

**c-Tetra-chloro-aniline**  $C_6HCl_4(NH_2)$ . [118°]. From *c*-tetra-chloro-nitro-benzene (Beilstein a. Kurbatoff, B. 11, 1862).

**Acetyl derivative** [154°] (Tust, B. 21, 1533). **Penta-chloro-aniline**  $C_6Cl_5NH_2$  [232°]. From *s*-di-chloro-aniline by chlorinating it in ethereal solution (Langer, A. 215, 120). Obtained also by reducing penta-chloro-nitro-benzene (Jungfleisch). Long white needles (from alcohol). V. sol. alcohol and ether, m. sol. benzoline. By further chlorination in acetic acid solution it gives penta-chloro-phenyl hypochlorite  $C_6Cl_5OCl$ .

**CHLORO-ANISIC-ACID v. Methyl derivative of CHLORO-OXY-BENZONIC-ACID.**

**CHLORO-ANISIDINE v. Methyl ether of CHLORO-AMIDO-PHENOL.**

**CHLORO-ANTHRACENE**  $C_{14}H_7Cl$ . [103°]. Obtained by fusing anthracene dichloride (Perkin, C. N. 84, 145). Golden-yellow needles, v. sol. ether, alcohol, and benzene. The picric acid compound forms scarlet needles.

**Di-(4)-chloro-anthracene**  $C_{14}H_8Cl_2$ . [209°]. Formed by the action of (2 mols. of) chlorine upon anthracene-(4)-carboxylic acid or upon (4, 1)-chloro-anthracene-(4, 2)-carboxylic acid (Behla, B. 20, 704). Prepared by chlorinating anthracene (Laurent, A. 84, 294; Perkin, C. J. 24, 14; Gräbe a. Liebermann, A. 160, 187; Suppl. 7, 284). Long yellow needles; v. sol. benzene, sl. sol. alcohol and ether. Not affected by boiling KOH. Gives anthraquinone on oxidation.

[255°]. From tetra-chloro-anthraquinone by heating with zinc-dust and aqueous ammonia (Kircher, A. 238, 347; B. 17, 1169). Slender needles. On oxidation it gives di-chloro-anthraquinone.

**Tri-chloro-anthracene**  $C_{14}H_5Cl_3$ . [163°]. From di-chloro-anthracene dichloride and alcoholic KOH (Schwarzer, B. 10, 378; cf. G. a. L.). Long golden needles (from alcohol). The alcoholic solution shows blue fluorescence.

[149°]. From tetra-chloro-benzoyl-benzoic acid (1 pt.), red phosphorus (3 pt.), and fuming HI (4 pt.) at 215° (Kircher, A. 238, 346). Slender needles, sol. benzene and chloroform.  $CrO_3$  gives the corresponding tetra-chloro-anthraquinone.

**Tetra-chloro-anthracene**  $C_{14}H_4Cl_4$ . [152°]. Prepared by the action of boiling alcoholic KOH on the di-chloro-anthracene tetrachloride [206°] obtained from nitroso-anthrone and  $PCl_5$  (Liebermann a. Lindermann, B. 13, 1589). Yellow needles, sol. hot acetic acid, sl. sol. alcohol. On oxidation with  $CrO_3$  it gives crystalline dichloro-anthraquinone.

**Tetra-chloro-anthracene**  $C_{14}H_4Cl_4$ . [164°] (H.). [220°] (G. a. L.). Formed by the action of alcoholic KOH upon pure di-chloro-anthracene tetrachloride [187°] (Hammerschlag, B. 19, 1108; Gräbe a. Liebermann, A. Suppl. 7, 283). Golden yellow needles. Sl. sol. nearly all solvents. By  $CrO_3$  and acetic acid it is oxidised to di-chloro-anthraquinone [205°].

**Hexa-chloro-anthracene**  $C_{14}H_2Cl_6$ . [320°-330°]. Yellow needles. Prepared by the action of  $SbCl_5$  on di-chloro-anthracene dichloride. Oxidation with  $K_2Cr_2O_7$  and  $H_2SO_4$  gives tetra-chloro-anthraquinone (Bolas, C. N. 28, 167; Diehl, B. 11, 175).

**Hepta-chloro-anthracene**  $C_{14}HCl_7$ . [above 350°]. Prepared by the prolonged action of  $SbCl_5$  on di-chloro-anthracene-dichloride at 260°. Sublimes in yellow needles (Diehl, B. 11, 176).

**Octo-chloro-anthracene**  $C_{14}H_0Cl_8$ . [above 350°]. Feathery crystals. Prepared by the prolonged action of  $SbCl_5$  at 280° on the lower chlorinated anthracenes (Diehl, B. 11, 177). Ruoff (B. 9, 1498) could only obtain hexa-chloro-benzene.

**DI-CHLORO-ANTHRACENE TETRA-BROMIDE**  $C_{14}H_2Cl_2Br_4$ . [166°] (S.); [178°] (Hammerschlag, B. 19, 1106). Obtained by exposing di-chloro-anthracene [209°] to bromine-vapour for a considerable time (G. a. L.; Schwarzer, B. 10, 376). Satiny needles (from benzene); sl. sol. alcohol and ether; v. sol. benzene and  $CHCl_3$ . At 180°-190° it is converted into di-chloro-bromo-anthracene [108°]. Boiling alcoholic KOH gives di-chloro-di-bromo-anthracene.

**(4, 1)-CHLORO-ANTHRACENE-(4, 2)-CARBOXYLIC ACID**  $C_{14}H_6O_4Cl_2$ .

$C_6H_4Cl_2$    $C_6H_4$ . [259°]. Obtained by heating anthracene with carbonyl chloride under pressure at 240°-250°; or by passing chlorine (1 mol.) into a solution of anthracene-(4)-carboxylic acid in  $CHCl_3$ . Long yellow glistening needles. Sublimes. Sol. alcohol, ether, and acetic acid; sl. sol. benzene, chloroform, and xylene; v. sl. sol. water and ligroin. Its solu-

tions have a blue fluorescence. At its melting-point it evolves  $\text{CO}_2$ , leaving (A)-chloro-anthracene. By  $\text{CrO}_3$ ,  $\text{KMnO}_4$ , or dilute  $\text{HNO}_3$  it is oxidised to anthraquinone. Alcoholic KOH at  $160^\circ$ – $170^\circ$  reduces it to anthracene-(A)-carboxylic acid. Chlorine converts it into di-(A)-chloro-anthracene. Salts.— $\text{KA}'$ : very slender yellow needles.— $\text{AgA}'$ : minute yellow prisms.— $\text{BaA}'_2$ : thick yellowish glistening prisms (from water) or needles (from alcohol).

*Methyl ether*  $\text{MaA}'$ : [ $123^\circ$ ]; yellow needles or large six-sided tables; sol. alcohol, ether, &c., with a blue fluorescence; insol. water (Behla, B. 20, 701).

**DI-CHLORO-ANTHRACENE DI-CHLORIDE**  $\text{C}_6\text{H}_2\text{Cl}_4$ . [ $150^\circ$ ]. Formed by passing chlorine into anthracene dissolved in chloroform (Schwarzer, B. 10, 377). Prisms (from chloroform); sl. sol. alcohol and ether, v. sol. benzene. At  $170^\circ$  it yields tri-chloro-anthracene [ $163^\circ$ ]. Boiling alcoholic KOH converts it into anthraquinone.

Di-chloro-anthracene-tetra-chloride  $\text{C}_6\text{H}_2\text{Cl}_6$ . [ $187^\circ$ ] (H.); [ $145^\circ$ ] (D.). Thin white needles. Prepared by passing chlorine for a long time through a benzene solution of anthracene or dichloranthracene [ $209^\circ$ ]. By treatment with alcoholic KOH it yields tetra-chloro-anthracene [ $164^\circ$ ] (Hammerschlag, B. 19, 1107; cf. Diehl, B. 11, 174).

Di-chloro-anthracene-tetrachloride  $\text{C}_6\text{H}_2\text{Cl}_6$ . [ $205^\circ$ – $207^\circ$ ]. White needles. Does not fluoresce. Prepared by heating nitroso-anthrone with  $\text{PCl}_5$  to  $180^\circ$ . By boiling with alcoholic KOH it gives tetra-chloro-anthracene [ $162^\circ$ ]. (Liebermann & Lindermann, B. 13, 1588).

**DI-CHLORO-ANTHRACENE DISULPHONIC ACID**  $\text{C}_6\text{H}_2\text{Cl}_2(\text{SO}_3\text{H})_2$ . From (1 pt.) di-chloro-anthracene [ $209^\circ$ ] and (5 pts.) fuming  $\text{H}_2\text{SO}_4$  at  $100^\circ$  (Perkin, C. J. 24, 15). Orange needles; v. sol. water but ppt. by  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ . Dilute solutions of the acid and its salts fluoresce blue. On oxidation it gives anthraquinone disulphonic acid.— $\text{Na}_2\text{A}''$  aq.— $\text{BaA}''$ .— $\text{SrA}''$ .

**CHLORO-ANTHRANILIC ACID** v. CHLORO-AMIDO-BENZOIC ACID.

**m-CHLORO-ANTHRAQUINONE**  $\text{C}_{14}\text{H}_9\text{ClO}_2$ , i.e.  $\text{C}_6\text{H}_3\text{Cl}(\text{CO})\text{C}_8\text{H}_6$ . [ $204^\circ$ ]. Formed by heating m-chloro-benzoyl-benzoic acid with sulphuric acid at  $160^\circ$ – $175^\circ$ . Yellowish-grey needles; v. sol. hot  $\text{C}_6\text{H}_6$ , sl. sol. acetic acid  $\text{CS}_2$ , and hot alcohol. Sublimes without decomposition (Grabbe, Rée, C. J. 49, 531).

Di-chloro-anthraquinone  $\text{C}_{14}\text{H}_6(\text{Cl}_2)_2$ . [ $205^\circ$ ]. Formed by oxidation of tetra-chloro-anthracene [ $164^\circ$ ] with  $\text{CrO}_3$  and acetic acid (Hammerschlag, B. 19, 1109; cf. Graebe & Liebermann, A. Suppl. 7, 290). Formed also by heating anthracene with  $\text{SbCl}_5$  at  $160^\circ$  (Diehl, B. 11, 179). Glistening golden needles (from acetic acid). By  $\text{NaOH}$  fusion it gives alizarin.

Di-chloro-anthraquinone  $\text{C}_{14}\text{H}_6(\text{Cl}_2)_2$ . [ $261^\circ$ ]. Formed by oxidising di-chloro-anthracene [ $255^\circ$ ]. Needles (from chloroform-alcohol). Gives alizarin when fused with potash (Kircher, B. 17, 1189).

Tri-chloro-anthraquinone  $\text{C}_{14}\text{H}_3\text{Cl}_3\text{O}_2$ . [ $284^\circ$ – $290^\circ$ ]. Got by heating anthraquinone with  $\text{SbCl}_5$

at  $180^\circ$  (Diehl, B. 11, 180). Yellow needles.

**Tetra-chloro-anthraquinone**  $\text{C}_{14}\text{H}_2(\text{Cl}_4)_2$ . [ $191^\circ$ ]. From tetra-chloro-o-benzoyl-benzoic acid and  $\text{H}_2\text{SO}_4$  at  $100^\circ$  (Kircher, A. 238, 344; B. 17, 1167). Golden needles (from benzene-alcohol). Oxidised by fuming  $\text{HNO}_3$  at  $140^\circ$  giving tetrachlorophthalic acid. Reduced by distillation with zinc-dust to anthracene. Yields phthalic acid on fusion with  $\text{NaOH}$ .

**Di-sulphonic acid**  $\text{C}_{14}\text{H}_2\text{Cl}_2\text{O}_4(\text{SO}_3\text{H})_2$ , Salts.— $\text{BaA}''$ .— $\text{CaA}''$ .

**Tetra-chloro-anthraquinone**  $\text{C}_{14}\text{H}_2\text{Cl}_4$ . [ $320^\circ$ – $330^\circ$ ]. Prepared by long heating of di-chloro-anthraquinone with 6 pts. of  $\text{SbCl}_5$  at  $200^\circ$  (Diehl, B. 11, 180). Yellow needles

**Penta-chloro-anthraquinone**  $\text{C}_{14}\text{HCl}_5\text{O}_2$ . Prepared by heating di-chloro-anthraquinone with 8 pts.  $\text{SbCl}_5$  at  $250^\circ$  (D.). Sublimes without melting. Insoluble in the ordinary solvents

**CHLORO-ATROPIC ACID**  $\text{C}_8\text{H}_7\text{ClO}_2$ . [ $85^\circ$ ] From tropic acid and  $\text{PCl}_5$ . Needles (Ladenburg, B. 12, 948).

**CHLORO-AZO-BENZENE** v. BENZENE-AZO-CHLORO-BENZENE, vol. i. p. 374.

Di-chloro-azo-benzene v. CHLORO-BENZENE-AZO-CHLORO-BENZENE, vol. i. p. 381.

**CHLORO-AZOPHENINE**  $\text{C}_{12}\text{H}_9\text{ClN}$ . [ $230^\circ$ ]. Formed by heating p-chloro-p-nitroso-di-phenylamine with aniline and aniline hydrochloride at  $100^\circ$ . Very similar to azophenine, but more sol. benzene (A. Fischer & Hepp, B. 20, 2481).

**Tri-chloro-azophenine**  $\text{C}_{12}\text{H}_6\text{Cl}_3\text{N}$ . [ $246^\circ$ ] (Fischer & Hepp, B. 21, 676).

**Tri-CHLORO-AZO-PHENOL** v. OXY-BENZENE-AZO-PHENOL, vol. i. p. 388.

**DI-CHLORO-BARBITURIC ACID**  $\text{C}_4\text{H}_2\text{Cl}_2\text{N}_2\text{O}_4$ , i.e.  $\text{CCl}_2(\text{CO.NH})_2$ . Formed by oxidising

di-chloro-oxy-methyl-uracil with fuming  $\text{HNO}_3$  (Behrend, A. 236, 64). Trimetric crystals, a:b:c = 777:1:893. V. sol. alcohol and ether; sol. water.

**CHLORO-BENZALDEHYDE** v. CHLORO-BENZOIC ALDEHYDE.

**CHLORO-ISOBENZALPHTHALIMIDINE** v. CHLORO-OXY-PHENYL-ISOUQUINOLINE.

**CHLORO-BENZAMIDE** v. Amide of CHLORO-BENZOIC ACID.

**CHLORO-BENZENE**  $\text{C}_6\text{H}_5\text{Cl}$ . Mol. w. 112}. [ $-40^\circ$ ] ( $182^\circ$ ). S.G.  $^{20}$  1.1066.  $\mu$  1.5369. R<sub>20</sub> 50.67 (Brühl). H.F.p. –11.220. H.F.w. –12.380 (Th.). S.H. ( $7^\circ$ – $64^\circ$ ) 326 (Schiff, G. 17, 486). Vapour-pressure, Ramsay & Young (C. J. 47, 654). S.V. 114.3 (Schiff, A. 220, 98); 114.5 (Ramsay).

**Formation**.—1. From phenol and  $\text{PCl}_5$  (Laurent & Gessard, A. 75, 79; Williamson & Scrnham, C. J. 7, 238; Riche, A. 121, 857).—2. By the action of chlorine on benzene in presence of iodine or other carriers (Hugo Müller, C. J. 15, 41; Fittig, A. 133, 49).—3. From benzene and  $\text{SOCl}_2$  at  $150^\circ$  (Dumas, Z. 1866, 705).—4. From  $\text{S}_2\text{Cl}_2$  and benzene at  $250^\circ$  (Schmidt, B. 11, 1178).—5. By heating benzene sulphochloride with  $\text{PCl}_5$  at  $210^\circ$  (Barbaccia & Kekulé, B. 5, 875).—6. A solution of disubstituted benzene chloride, prepared from 80 grms. of aniline, and a large excess of  $\text{HCl}$  is slowly run into a nearly boiling solution of  $\text{Cu}_2\text{Cl}_2$  in  $\text{HCl}$  (150 grms. of a 10 p.c. solution of  $\text{Cu}_2\text{Cl}_2$ ). The bromo-benzene is distilled off with steam (Sandmeyer, B. 17,

[1885].—7. By heating diazobenzene with a large excess of strong HCl; the yield is 40 p.c. of the theoretical (Gasiorowski a. Wajss, *B.* 18, 1936).

**Properties.**—Colourless liquid. When led through a red-hot tube it forms diphenyl, chlorodiphenyl, di-chloro-diphenyl, and di-phenylbenzene (Kramers, *A.* 189, 135). Not affected by boiling with  $\text{Al}_2\text{O}_3$ . Converted by sodium into diphenyl.  $\text{MnO}_2$  and  $\text{H}_2\text{SO}_4$  give formic and *p*-chloro-benzoic acid (Carius, *Z.* [2] 49, 505; C. Müller, *Z.* [2] 5, 137). Chloro-benzene passes out of the system as chloro-phenyl-mercapturic acid  $\text{C}_6\text{H}_4\text{ClNSO}_2$ .

***o*-Di-chloro-benzene**  $\text{C}_6\text{H}_4\text{Cl}_2$  [1:2]. Mol. w. 147. (179° i. V.). S.G. 1.328 (B. a. K.); 1.325 (F. a. C.).

**Formation.**—1. In small quantity, by chlorinating benzene (Beilstein a. Kurbatoff, *A.* 176, 42; 182, 94; *B.* 7, 1398, 1759). Separated from the greater part of the solid *p*-di-chloro-benzene by pressure; it is then heated with fuming  $\text{H}_2\text{SO}_4$  at 210° for 2 days; this sulphonates only *o*-di-chloro-benzene. The resulting sulphonic acid is purified by crystallisation, and reconverted into di-chloro-benzene by hydrolysis (Friedel a. Crafts, *A. Ch.* [6] 10, 411).—2. From *o*-chloro-phenol and  $\text{PCl}_5$  (B. a. K.).

**Properties.**—Liquid. Gives a nitro-derivative [48°].  $\text{MeCl}$  and  $\text{Al}_2\text{Cl}_6$  at 100° give chiefly hexa-methylbenzene and tri-chloro-mesitylene (F. a. C.).

***m*-Di-chloro-benzene**  $\text{C}_6\text{H}_4\text{Cl}_2$  [1:3]. (168° uncorr.) (S.); (172°) (K.). S.G. 1.307.

**Formation.**—1. By running an aqueous solution of  $\text{NaNO}_2$  into a hot solution of *m*-phenylenediamine and  $\text{Cu}_2\text{Cl}_2$  in dilute HCl (Sandmeyer, *B.* 17, 2652).—2. From di-chloro-aniline by removing  $\text{NH}_2$  by the diazo-reaction (Körner, *G.* 4, 341; B. a. K.).—3. From *m*-di-nitro-benzene via *m*-nitro-aniline, *m*-chloro-nitro-benzene, and *m*-chloro-aniline (Griess, *P. T.* 1864 [3] 705).

**Properties.**—Liquid.  $\text{HNO}_3$  (S.G. 1.4) gives a nitro-compound [32°].

***p*-Di-chloro-benzene**  $\text{C}_6\text{H}_4\text{Cl}_2$  [1:4]. [55°]. (175°). S.G. 1.458; 1.241 (Jungfleisch, *A. Ch.* [4] 14, 186).  $\Delta$  V.S. 117.4 (Schiff).

**Formation.**—1. By running a solution of  $\text{NaNO}_2$  into a hot solution of *p*-phenylenediamine and  $\text{Cu}_2\text{Cl}_2$  in dilute HCl (Sandmeyer, *B.* 17, 2652).—2. The chief product of the action of chlorine (2 mols.) on benzene (1 mol.) in presence of iodine (Hugo Müller, *C. J.* 15, 41; *Z.* 1864, 401; Körner, *G.* 4, 324) or in presence of  $\text{MoCl}_5$  (Aronheim, *B.* 8, 1400).—3. By the action of  $\text{PCl}_5$  on phenol *p*-sulphonic acid (Kekulé, *B.* 6, 944) or on *p*-chloro-phenol (Beilstein a. Kurbatoff, *A.* 176, 82; *B.* 7, 1395, 1769).

**Properties.**—Monoclinic laminae (from alcohol). Sublimes at ordinary temperatures. Fuming  $\text{HNO}_3$  gives a nitro-derivative [55°].

***o*-Tri-chloro-benzene**  $\text{C}_6\text{H}_3\text{Cl}_3$  [1:3:4]. Mol. w. 181. [163°]. (213° i. V.). S.G. (of liquid) 1.465.

**Formation.**—1. By chlorination of benzene in presence of iodine (Jungfleisch, *A. Ch.* [4] 15, 264).—2. From di-chloro-aniline,  $\text{C}_6\text{H}_4(\text{NH}_2)\text{Cl}_2$  [1:3:4] or [1:2:4] displacing  $\text{NH}_2$  by  $\text{Cl}$  by means of the diazo-reaction.—3. From di-chloro-phenol [48°] and  $\text{PCl}_5$  (Beilstein a. Kurbatoff, *A.* 192, 230; *B.* 10, 270).—4. From ( $\beta$ )-benzene hexachloride and alcoholic KOH.

**Properties.**—Gives on nitration a nitro-derivative [58°].

***c*-Tri-chloro-benzene**  $\text{C}_6\text{H}_3\text{Cl}_3$  [1:2:3]. [54°]. (219°). By eliminating  $\text{NH}_2$  from  $\text{C}_6\text{H}_3(\text{NH}_2)\text{Cl}_2$  [1:2:3:4] by diazo-reaction (Beilstein a. Kurbatoff, *A.* 192, 235). Also from (1,2,3)-di-chloro-aniline by displacing  $\text{NH}_2$  by  $\text{Cl}$ . V. sol.  $\text{CS}_2$  and benzene, sl. sol. alcohol. Gives a nitro-derivative [56°].

***s*-Tri-chloro-benzene**  $\text{C}_6\text{H}_3\text{Cl}_3$  [1:3:5]. [55°]. (208.5° i. V.). From ordinary tri-chloro-aniline, by eliminating  $\text{NH}_2$  by diazo-reaction (Körner). Also from chloro-benzene tetra-chloride, and alcoholic KOH (Jungfleisch). V. sol. ether, benzene,  $\text{CS}_2$ , and light petroleum. Sol. cold alcohol and dilute (50 p.c.) acetic acid. Gives on nitration a nitro-derivative [68°] (B. a. K.), or, when fuming  $\text{HNO}_3$  is used, a di-nitro-derivative [130°] (Jackson a. Wing, *Am.* 9, 348).

***c*-Tetra-chloro-benzene**  $\text{C}_6\text{H}_2\text{Cl}_4$  [1:2:3:4]. Mol. w. 216. [46°]. (254° i. V.). From tri-chloro-aniline  $\text{C}_6\text{H}_3\text{Cl}_3(\text{NH}_2)$  [1:2:3:4] or [1:3:6:2] by the diazo-reaction (Beilstein a. Kurbatoff, *A.* 192, 238). Long needles (from alcohol). Sl. sol. alcohol, v. sol. ether, light petroleum,  $\text{CS}_2$ , and strong (90 per cent.) acetic acid. Gives a nitro-derivative [65°].

***i*-Tetra-chloro-benzene**  $\text{C}_6\text{H}_2\text{Cl}_4$  [1:3:4:5]. [51°] (B. a. K.); [35°] (I.). (246° i. V.). From ordinary tri-chloro-aniline displacing  $\text{NH}_2$  by  $\text{Cl}$  by the diazo-reaction (Beilstein a. Kurbatoff, *A.* 192, 238). Obtained also by chlorinating benzene in sunlight (Istrati, *A. Ch.* [6] 6, 883). Colourless needles (from alcohol). Sl. sol. cold alcohol, sol. benzene, v. sol.  $\text{CS}_2$  or light petroleum.  $\text{HNO}_3$  (S.G. 1.54) gives a nitro-derivative [30°] (Jungfleisch, *A. Ch.* [4] 15, 204), or [22°] (B. a. K.).

***s*-Tetra-chloro-benzene**  $\text{C}_6\text{H}_2\text{Cl}_4$  [1:2:4:5]. [138°] (245° i. V.) (B.). S.G. 1.734; 1.399.

**Formation.**—1. By chlorination of benzene (Jungfleisch).—2. From  $\text{C}_6\text{H}_4\text{Cl}_2(\text{NO}_2)$  [1:2:3:4] by reduction followed by the diazo-reaction (Beilstein a. Kurbatoff, *A.* 192, 236).—3. In small quantity by the action of chlorine on boiling tri-chloro-toluene (Beilstein a. Kuhlberg, *A.* 152, 247).—4. By the action of  $\text{Fe}_2\text{Cl}_6$  upon (2, 4, 6, 1)-tri-chloro-phenol (Dacomo, *B.* 18, 1183).

**Properties.**—Crystallises best from benzene. Sl. sol. alcohol or light petroleum. Fuming  $\text{HNO}_3$  forms, besides the nitro-compound [98°], tetra-chloro-quinone. This is the only tetra-chloro-benzene which gives chloranil under these circumstances.

***n*-Penta-chloro-benzene**  $\text{C}_6\text{HCl}_5$ . [36°]. (276°) (Ladenburg, *A.* 172, 344). S.G. 1.842. Formed by chlorinating benzene (J.), di-phenyl sulphone (Otto a. Ostrop, *A.* 141, 93; 154, 182) or tetra-chloro-benzyl chloride (Beilstein a. Kuhlberg, *A.* 152, 247). Slender needles (from alcohol); v. sl. sol. cold alcohol, v. sol. ether and  $\text{CS}_2$ . After heating for a long time with conc. or fuming  $\text{H}_2\text{SO}_4$ , on pouring the liquid into water a chestnut-brown pp. containing no sulphur and 86.8 p.c. chlorine is formed; it is called 'francosine' by Istrati (*BHP* [2] 48, 35); it is a red dye, and forms a red solution in alcohol.

**Hexa-chloro-benzene**  $\text{C}_6\text{Cl}_6$ . Mol. w. 285. [226°]. (328°). S.G. 1.569.

**Formation.**—1. From methylene chloride and  $\text{ICl}$  or  $\text{ICl}_3$  (Holand, *A.* 240, 254).—2. By passing chloroform,  $\text{CCl}_3\text{H}$ , or  $\text{C}_2\text{Cl}_4$  through a red hot

tube (Julius; Regnault, *A.* 30, 350; Basset, *C. J.* 20, 448; Berthelot & Jungfleisch, *Z.* [2] 4, 565).—

3. By chlorinating benzene in presence of SbCl<sub>3</sub> (Hugo Müller, *Z.* 1864, 40).—4. From tetra-chloro-quinone (chloranil) and PCl<sub>5</sub> (Gräbe, *A.* 146, 1).—5. Is the ultimate product of the action of SbCl<sub>3</sub> with chlorine on all chloro-toluenes and chloro-xylenes (Beilstein & Kuhlberg, *Z.* [2] 5, 183; *A.* 150, 309).—6. By the action of chlorine in presence of ICl upon all aromatic hydrocarbons, as well as upon aniline, phenol, thymol, camphor (Ruoff, *B.* 9, 1483; 10, 1234); sec-hexyl iodide (Kraft, *B.* 9, 1085); and hexa-chloro-acetone (Cloeze, *A. Ch.* [6] 9, 145).

**Properties.**—Thir prisms (from alcohol-benzene), v. sl. sol. boiling alcohol, sl. sol. ether, m. sol. benzene. When heated with glycerol and NaOH it gives penta-chloro-phenol.

**CHLORO-BENZENE-AZO. v. AZO-COMPOUNDS.**

**CHLORO-BENZENE HEXA-CHLORIDE**

$C_6H_2Cl_6$ . [257°]. From di-phenyl sulphone and chlorine in sunlight (Otto, *A.* 142, 51). Small dimetric prisms (from alcohol); v. sl. sol. ether, sl. sol. hot alcohol.

Di-chloro-benzene hexa-chloride  $C_6H_2Cl_6$  [above 250°]. From chloro-benzene and chlorine in sunlight (Jungfleisch, *Z.* [2] 4, 486). Prisms (from chloroform); converted into penta-chloro-benzene by boiling alcoholic KOH.

Tri-chloro-benzene hexa-chloride  $C_6H_2Cl_6$  [1:2:4]. [96°]. Formed by chlorination of benzene (Willgerodt, *J. pr.* [2] 35, 415). Smells of rotten straw. V. e. sol. ether, v. sol. alcohol. Alcoholic KOH converts it into  $C_6Cl_6$  [236°].

**CHLORO-BENZENE SULPHINIC ACID**

$C_6H_4ClSO_2H$ . [90°]. From chloro-benzene (?) sulpho-chloride and sodium-amalgam (Otto & Brummer, *A.* 143, 113; 145, 323; 146, 243). Small needles or long thin columns; sl. sol. cold water. Reduced by Zn and  $H_2SO_4$  to chloro-phenyl mercaptan, and by sodium-amalgam to benzene sulphinic acid. Oxidation gives chloro-benzene sulphonic acid.

**Salts.**— $NaA$ , 2aq.— $CaA$ ,— $BaA$ ,— $PbA$ ,—*Ethyl ether*  $EiA$ . [123°]. Needles.

**CHLORO-BENZENE o-SULPHONIC ACID**  
 $C_6H_4ClSO_3H$ , i.e.  $C_6H_4Cl(SO_3H)$  [1:2]. From amido-benzene o-sulphonic acid by displacement of  $NH_2$  by Cl by means of the diazo-reaction (Bahlmann, *A.* 186, 825).

**Chloride**  $C_6H_4ClSO_2Cl$  [29°].

**Amide**  $C_6H_4ClSO_2NH_2$  [188°].

**Chloro-benzene m-sulphonic acid**

$C_6H_4Cl(SO_3H)$  [1:3]. Prepared similarly from amido-benzene m-sulphonic acid (Kieselinsky, *A.* 180, 108). Deliquescent plates.— $AgA$ ,— $KA$ ,— $CaA$ ,— $BaA$ , 2aq.— $CuA$ , 5aq.

**Chloride**  $C_6H_4Cl(SO_2Cl)$ . Oil.

**Amide**  $C_6H_4Cl(SO_2NH_2)$  [148°]; plates.

**Chloro-benzene p-sulphonic acid**  $C_6H_4ClSO_3H$  [1:4]. Formed by sulphonating chloro-benzene (Otto & Brummer, *A.* 143, 102; Lindow & Otto, *Z.* [2] 4, 39; Glutz, *A.* 143, 184). Also by the same method as the two preceding acids (Goslich, *A.* 180, 106). Deliquescent needles or prisms. Potash-fusion gives resorcin (Oppenheim & Vogt, *A. Suppl.* 6, 376). The Na salt fused with KCN gives terephthalonitrile  $C_6H_4(CN)_2$ .

**Salts.**— $NaA$ , 1aq.— $KA$ ,— $AgA$ ,— $CaA$ , 1½aq.— $BaA$ , 2aq.— $PbA$ , 2aq.— $CuA$ , 5aq.

**Chloride**  $C_6H_4ClSO_2Cl$  [53°].

**Bromide**  $C_6H_4ClSO_2Br$  [53°].

**Amide**  $C_6H_4ClSO_2NH_2$  [144°].

**Anilide**  $C_6H_4ClSO_2NPh$ . [104°]. Needles (Wallach & Huth, *B.* 9, 426).

**Di-chloro-benzene sulphonic acid**

$C_6H_3Cl_2(SO_3H)$  [1:2:2]. From o-di-chloro-benzene and fuming  $H_2SO_4$  at 210° (Beilstein & Kurbatoff, *A.* 176, 41; 182, 94).— $CaA$ , 2aq.— $BaA$ , 2aq.— $PbA$ , 2aq.

**Di-chloro-benzene sulphonic acid**

$C_6H_3Cl_2(SO_3H)$  [1:3:2]. From m-di-chloro-benzene and fuming  $H_2SO_4$  at 235° (B. & K.).— $CaA$ , 2aq.— $BaA$ , 2aq.— $PbA$ , 2aq.

**Di-chloro-benzene sulphonic acid**

$C_6H_3Cl_2(SO_3H)$  [1:4:2]. From p-di-chloro-benzene and vapours of  $SO_2$  (Lesimple, *Z.* [2] 4, 226). Conc.  $H_2SO_4$  has no action even at 230° (B. & K.). Trimetric prisms (from water).— $NH_4A$ , 1aq.; needles, m. sol. water.— $KA$ , 1aq.— $AgA$ ,— $NaA$ , 1aq.; six-sided tablets.— $MgA$ , 6aq.— $BaA$ ,; laminae.— $PbA$ , 3aq.

**Tri-chloro-benzene sulphonic acid**

$C_6H_2Cl_3(SO_3H)$  [1:3:4:67]. From u-tri-chloro-benzene and fuming  $H_2SO_4$  (Beilstein & Kurbatoff, *A.* 192, 231).— $CaA$ , 2aq.— $BaA$ , 2aq.— $PbA$ , 2aq.

**CHLORO-BENZENE THIO-SULPHONIC**

**ACID. Chloro-phenyl ether**  $C_6H_4ClSO_2$ , i.e.  $C_6H_4ClSO_2.S.C_6H_5$  [138°]. From chloro-benzene sulphonic acid and water at 130° (Otto, *A.* 145, 323). Small, four-sided, trimetric columns (from alcohol). Reduced by zinc and  $H_2SO_4$  to chloro-phenyl mercaptan.

**DI-CHLORO-BENZIDINE v. DI-CHLORO-DI-AMIDO-DIPHENYL.**

**CHLORO-BENZIL or Benzil chloride v. BENZILIC ACID, Reaction 5.**

**CHLORO-BENZO-TRICHLORIDE v. TETRACHLORO-TOLUENE.**

**o-CHLORO-BENZOIC ACID**  $C_6H_4ClO_2$ , i.e.  $C_6H_4Cl(COOH)$  [1:2]. Mol. w. 156. [187°]. S. 114 at 0°. Electrical conductivity: Ostwald (*J. pr.* [2] 32, 349).

**Formation.**—1. From salicylic acid (1 mol.) and PCl<sub>5</sub> (2 mols.); the mixture is distilled and the portion (above 258°) containing  $C_6H_4ClCOCl$  is decomposed by water (Chiozza, *A. Ch.* [3] 36, 102; Kolbe & Lautemann, *A.* 115, 184; Beilstein & Reichenbach, *A.* 139, 311; Hübner, *Z.* 1870, 293; *A.* 147, 263; Wilkins & Rack, *A.* 222, 192). 2. By boiling o-chloro-toluene with dilute  $KMnO_4$  (Emmerling, *B.* 8, 880).—3. By heating m-chloro-nitro-benzene with alcoholic KCy at 260° (Richter, *B.* 4, 463).

**Properties.**—Large needles. Melts under water. W. sol. hot water, alcohol, and ether. Gives a yellow pp. in neutral solutions with  $FeCl_3$ .

**Reactions.**—1. Soda-fusion gives about equal quantities of o- and m-oxy-benzoic acids (Ost, *J. pr.* [2] 11, 385).—2. In hot aqueous solution it is reduced to benzoic acid by sodium-amalgam. Benzoic acid so prepared was called 'salylic' acid until Beilstein & Schlun (*A.* 183, 239) showed it to be ordinary benzoic acid contaminated with its crystallisation.—3. Fusion with sodium formate gives benzoic acid (V. Meyer, *B.* 3, 363; 4, 259).

**Salts.**— $BaA$ , 8aq.— $BaA$ , S. 31 at 18°.—

**CaA'**, 2aq; v. sol. water; v. sl. sol. alcohol.—  
**AgA'**: scales (from boiling water).

*Ethyl ether EtA'*. (c. 240°) (Kekulé, *Rép. chim. pure*, 1861, 308).

*Chloride*  $C_6H_4Cl.COCl$ . (c. 237°).

*Amide*  $C_6H_4Cl.CONH_2$ : [139°]; needles; v. sl. sol. cold water; v. sol. alcohol and ether.

*Anilide*  $C_6H_4Cl.CONPhH$ : [114°]; needles.

*p-Nitro-anilide*  $C_6H_3Cl.NO_2.NH.C_6H_4NO_2$ : [180°]; from the anilide and  $HNO_3$  (Wilkins a. Rack, A. 222, 192).

*p-Toluide*  $C_6H_3Cl.CO.NHC_6H_4(CH_3)$ : [131°]; colourless crystals; sol. alcohol, nearly insol. water (Schreib, B. 13, 465).

*m-Nitro-p-toluide*  $C_6H_3Cl.CO.NHC_6H_3(CH_3)(NO_2)$ : [189°]; yellowish crystals; sol. acetic acid, sl. sol. alcohol, insol. water. Prepared by nitration of the *p*-toluide.

*Di-nitro-p-toluide*  $C_6H_2Cl.CO.NHC_6H_2(CH_3)(NO_2)_2$ : [228°]; colourless crystals. Sl. sol. alcohol, v. sol. acetic acid and chloroform. Prepared by further nitration of the mono-nitro-compound.

*Tri-nitro-p-toluide*  $C_6H_2Cl.CO.NHC_6H_2(NO_2)_3$ : [239°]; colourless crystals. Prepared by still further nitration of the above.

*m-Amido-p-toluide*  $C_6H_3Cl.CO.NHC_6H_3(CH_3)(NH_2)$ : [153°]; colourless crystals; sol. alcohol. Prepared by reduction of the *m*-nitro-*p*-toluide.— $B'HNO_2$ .

*Benzoylamido-p-toluide*  $C_6H_3Cl.CO.NHC_6H_3(CH_3)(NHCO_2C_6H_5)$ : [178°]; colourless needles, sl. sol. alcohol.

*Nitrile*  $C_6H_4Cl.CN$ . *o-Chloro-cyano-benzene*. [43°]. (232°). From the amide and  $CaCl_2$  or  $P_2S_5$ . Also from the amide or nitrile of salicylic acid by the action of  $PCl_5$  (Henry, B. 2, 492). Long needles; sl. sol. boiling water: m. sol. alcohol and ether.

*m-Chloro-benzoic acid*  $C_6H_4Cl.CO_2H$  [1:3]. [153°]. S. 0.35 at 0°. *Electrical conductivity*: Ostwald, J. pr. [2] 32, 349.

*Formation*.—1. By chlorinating benzoic acid by treatment with chlorine, with  $HCl$  and  $KClO_4$ , or with a boiling solution of bleaching powder (Herzog, *N. Br. Arch.* 23, 15; Scharling, A. 41, 49; 42, 268; Stenhouse, A. 55, 1; Field, A. 65, 55; Otto, A. 122, 157; Hübner a. Weiss, B. 6, 175).—2. From *m*-amido-benzoic acid by the diazo-reaction.—3. By distilling *m*-sulpho-benzoic acid (1 mol.) with  $PCl_5$  (2 mols.) and treating the resulting *m*-chloro-benzoyl chloride with water (Limpricht a. Usler, A. 102, 259).—4. By oxidation of *m*-chloro-toluene with chromic acid mixture (Wroblewsky, A. 168, 200).—5. From *p*-chloro-nitro-benzene and  $KCy$  at 200° (Richter, B. 4, 463).—6. From *p*-chloro-amido-benzoic acid by removing  $NH_2$  by the diazo-reaction (Hübner, A. 222, 91).

*Properties*.—Long needles or small prisms. Does not melt under water.

*Reactions*.—1. *Sodium amalgam* reduces it to benzoic acid (Beilstein a. Reichenbach, A. 132, 315).—2. *Potash-fusion* gives *m*-oxy-benzoic acid (Demby, A. 148, 222).

*Salts*.—**CaA'**, 8aq; small needles. S. 1.21 at 12°.—**BaA'**, 4aq; small needles.—**AgA'**.

*Ethyl ether*  $C_6H_4Cl.CO_2Et$ : (245°); liquid.

*Chloride*  $C_6H_4Cl.COCl$ : (225°); liquid.

*Amide*  $C_6H_4Cl.CONH_2$ : [133°]; needles.

*Nitrile*  $C_6H_4Cl.CN$ : [39°]. Formed by dis-

tilling *m*-sulpho-benzamide with  $PCl_5$  (Limpricht a. Usler, A. 106, 35). Also from the nitrile of *m*-amido-benzoic acid by displacement of  $NH_2$  by  $Cl$  (Griess, B. 2, 370). Needles; insol. water. Volatile with steam.

*p-Chloro-benzoic acid*  $C_6H_4Cl.CO_2H$  [1:4]. *Chloro-dracrylic acid*. [236°]. S. 0.19. *Electrical conductivity*: Ostwald, J. pr. [2] 32, 349.

*Formation*.—1. From *p*-amido-benzoic acid by diazo-reaction (Wilbrand a. Beilstein, A. 128, 257; Beilstein a. Schlun, A. 133, 242).—2. By oxidation of *p*-chloro-toluene with  $CrO_3$  (Beilstein a. Geitner, A. 139, 336) or dilute  $KMnO_4$  (Emmerling, B. 8, 880).—3. From chloro-benzene, dilute  $H_2SO_4$ , and  $MnO_2$  (Carl Müller, Z. [2] 5, 137).

*Properties*.—Needles (by sublimation); v. sl. sol. water, v. sol. alcohol and ether. *Sodium amalgam* reduces it to benzoic acid (Hartmann, J. pr. [2] 12, 204).

*Salts*.—**BaA'**, 4aq.—**CaA'**, 8aq.—**AgA'**.

*Methyl ether MeA'*: [42°]; needles.

*Chloride*  $C_6H_4Cl.COCl$ : [222°].

*Amide*  $C_6H_4Cl.CONH_2$ : [170°]; needles.

*Anilide*  $C_6H_4Cl.CONPhH$ : [194°]; needles. Di-chloro-benzoic acid  $C_6H_3Cl_2.CO_2H$  [6:2:1]. Mol. w. 191. [126-5°]. Formed, together with the two isomerides [156°] and [201°], by the action of water on crude penta-chloro-toluene  $C_6H_2Cl_5.CCl_4$  at 200° (Schultz, A. 187, 269). Slender needles; volatile with steam.

*Salts*.—**KA'**, 5aq.—**NH\_4A'**, aq.—**BaA'**, 8½aq. S. (of **BaA'**, in alcohol) 3.8 at 4°.—**ZnA'**, 1½aq.

*Chloride*  $C_6H_3Cl_2.COCl$ : (244°); liquid.

*Amide*  $C_6H_3Cl_2.CONH_2$ : [166°]; needles.

Di-chloro-benzoic acid  $C_6H_3Cl_2.CO_2H$  [2:5:1]. [156°]. (301°). S. 0.850 at 14°.

*Formation*.—1. From chloro-nitro-benzoic acid [164°] by reduction and displacement of  $NH_2$  by  $Cl$  by means of the diazo-reaction (Wilkins a. Rack, A. 222, 201).—2. From crude penta-chloro-toluene  $C_6H_2Cl_5.CCl_4$ , together with the acids [126-5°] and [201°] (Schultz, A. 187, 268).—3. By chlorinating *o*-chloro-benzoic acid in presence of  $SbCl_5$  (Beilstein, A. 179, 286). Occurs also among products of chlorination of benzoic acid.—4. By oxidising (6, 3, 1)-di-chloro-ethyl-benzene with chromic mixture (Istrati, A. Ch. [6] 6, 479).—5. From  $C_6H_4MeCl$  [1:2:5] and dilute  $HNO_3$  (Lellmann a. Klotz, A. 231, 319).

*Needles* (from water); slightly volatile with steam. Heated with dilute  $H_2SO_4$  at 220° gives  $CO_2$  and *p*-dichloro-benzene.—**BaA'**, 8aq. S. (of **BaA'**) 2.5 at 14.4°.—**CaA'**, 2aq.—**PbA'**, aq.—**CuA'**, 2aq (B.).—**CuA'**, aq (L.).—**FeA'**.—**KA'**, 2aq. **NH\_4A'**: slender needles.—**AgA'**.

*Ethyl ether EtA'*. (271° i. V.). S.G. 2.1328.

*Amide*  $C_6H_3Cl_2.CONH_2$ : [165°]; needles (B.).

*Anilide*: [240°]; prisms (from benzene).

Di-chloro-benzoic acid  $C_6H_3Cl_2.CO_2H$  [3:2:1].

[156°] (G.). [166°] (S.). Formed, together with the isomeride [201°], by chlorination of benzoic acid (Claus, B. 5, 658; 6, 721; 8, 948; 20, 1621). Formed also by oxidising *c*-di-chloro-toluene with  $KMnO_4$  (Seelig, A. 237, 162). Not affected by dilute  $H_2SO_4$  at 220°. Distillation over lime gives *o*-di-chloro-benzene. Not decomposed by conc.  $H_2SO_4$  at 300°.—**BaA'**, 8aq. S. at 28°.

Di-chloro-benzoic acid  $C_6H_3Cl_2.CO_2H$  [4:2:1]. [158°]. From  $C_6H_4MeCl$  [1:2:4] and dilute  $HNO_3$  (Lellmann a. Klotz, A. 231, 316).

Salt. —BaA', 3½ aq.

Di-chloro-benzoic acid  $C_6H_4Cl_2(CO_2H)$  [3:5:1]. [182°]. From  $C_6H_5MeCl$  and dilute  $HNO_3$  (Lellmann a. Klotz, A. 231, 324). Needles (from dilute alcohol). May be sublimed.

Di-chloro-benzoic acid  $C_6H_4(CO_2H)Cl_2$  [4:3:1]. [201°].

**Formation.**—1. A product of the chlorination of benzoic acid (Beilstein a. Kuhlberg, A. 152, 232; 179, 201).—2. From chloro-sulpho-benzoic acid and  $PCl_5$  (Otto, A. 123, 226).—3. By oxidation of  $C_6H_4Cl_2CH_3$  or  $C_6H_3Cl_2CH_2Cl$ ; or by heating  $C_6H_4Cl_2CCl_3$  with water at 200° (B. a. K.).—4. From p-chloro-benzoic acid and  $SbCl_5$  at 200° (B.).—5. From chlorinated p-oxy-benzoic acid and  $PCl_5$  (Lössner, J. pr. [2] 13, 433).—6. From  $C_6H_5MeCl_2$  [1:3:4] by dilute  $HNO_3$  (Lellmann a. Klotz, A. 231, 313).

**Properties.**—Very slender needles (from water); volatile with steam.

Salts.—CaA', 3 aq.—BaA', 4 aq. S. 1:1 at 18°.

Ethyl ether EtA': (263°); liquid.

Chloride  $C_6H_4Cl_2COCl$ : (242°); liquid.

Amide  $C_6H_4Cl_2CONH_2$ : [133°]; needles.

Tri-chloro-benzoic acid  $C_6H_3Cl_3(CO_2H)$  [6:3:2:1]. [c. 80°]. From the corresponding aldehyde and  $KMnO_4$  (Seelig, A. 237, 150). Needles, v. sol. water.

Tri-chloro-benzoic acid  $C_6H_2Cl_4(CO_2H)$  [4:3:2:1]. Mol. w. 225½. [129°]. From the corresponding (4, 3, 2, 1)-tri-chloro-benzoic aldehyde by  $KMnO_4$  (Seelig, A. 237, 150). Needles; m. sol. water.

Tri-chloro-benzoic acid  $C_6H_3Cl_3(CO_2H)$  [5:4:2:1]. [163°]. From s-tri-chloro-toluene by oxidation with chromic acid mixture (Jungasch, A. 142, 301). Formed also by boiling benzoic acid with water and bleaching-powder for a long time; and by heating  $C_6H_4Cl_2CCl_3$  with water at 260° (Beilstein a. Kuhlberg, A. 152, 234). Slender needles (from water or by sublimation); v. sl. sol. cold water.

Salts.—NH<sub>4</sub>A'.—CaA', 2 aq.—BaA', 7 aq.—SrA', 4 aq.

Ethyl ether EtA': [65°]; needles.

Chloride  $C_6H_3Cl_3COCl$ : [41°]. [272°].

Amide  $C_6H_3Cl_3CONH_2$ : [168°]; needles.

Tri-chloro-benzoic acid  $C_6H_2Cl_4(CO_2H)$  [5:4:3:1]. [203°].

**Formation.**—1. From di-nitro-p-amido-benzoic acid and fuming  $HCl$  at 210° (Salkowski, A. 163, 28).—2. From crude hexa-chloro-toluene  $C_6H_2Cl_6$ ,  $CCl_4$  and  $NaOH$  (Claus a. Bücher, B. 20, 1626).

**Properties.**—Slender needles (from dilute alcohol or by sublimation).

Salts.—AgA'.—BaA', 4 aq.—CaA', 6 aq.

Ethyl ether EtA': [86°]; slender needles (S.).

Chloride  $C_6H_2Cl_4COCl$ : [36°] (S.).

Amide  $C_6H_2Cl_4CONH_2$ : [176°] (S.).

c-Tetra-chloro-benzoic acid  $C_6HCl_4(CO_2H)$  [165°]. Formed by chlorination of the di-chloro-benzoic acids melting at [201°] and [156°] (Claus) by heating with  $MnO_2$  and fuming  $HCl$  at 190° (Claus a. Bücher, B. 20, 1626). Also from di-chloro-benzoic acid [156°] and  $SbCl_5$  at 230° (Beilstein, A. 179, 286).—BaA', 4 aq (B.).—BaA', 3½ aq (C.).

Tetra-chloro-benzoic acid  $C_6HCl_4(CO_2H)$  [5:4:3:2:1]. [186°]. Prepared by heating tetra-

chloro-phthalic acid with acetic acid (2 or 3 pts.) at 300° for 3 or 4 hours (Tust, B. 20, 2430; 21, 1532). Long colourless needles. V. sol. alcohol and ether, v. sl. sol. water.

Salts.—A', Ca 4 aq: long colourless needles; m. sol. hot water.—A', Cu 3½ aq.—BaA', 3½ aq.

Ethyl ether A'Et: [85°]; long colourless needles.

Tetra-chloro-benzoic acid  $C_6HCl_4(CO_2H)$  [6:4:3:2:1]? [186°]. From hepta-chloro-toluene  $CHCl_3CCl_3$  and water at 230° (Beilstein a. Kuhlberg, A. 152, 245).

Penta-chloro-benzoic acid  $C_6Cl_5(CO_2H)$  [200°]. Formed by chlorination of the di-chloro-benzoic acids [201°] and [156°] with  $MnO_2$  and  $HClAq$  at 190° (C. a. B.).—BaA', 4 aq: stellate groups of needles.

Nitrile  $C_6Cl_5(CN)$ . [210°]. Formed by exhaustive chlorination of benzonitrile with  $SbCl_5$  (Merz a. Weith, B. 16, 2385). Colourless needles. Sublimable. V. sol: hot alcohol, chloroform, and  $CS_2$ , sl. sol. cold alcohol and ether. It is very stable towards  $HCl$  at high temperatures. Alcoholic  $NaOH$  removes all its chlorine at 200°.

o-CHLORO-BENZOIC ALDEHYDE [2:1]  $C_6H_4ClCHO$ . (c. 215°). S.G. = 1.29. Formed by heating tri-chloro-toluene  $C_6H_3Cl_3CH_3$  (from salicylic aldehyde and  $PCl_5$ ) with water at 170° or with (½ pt.) dry oxalic acid at 130° (Henry, B. 2, 135; Anschütz, A. 226, 19). Oil, smelling of almonds; volatile with steam. Forms a crystalline compound with  $NaHSO_4$ .

p-Chloro-benzoic aldehyde [4:1]  $C_6H_4ClCHO$ . [48°]. (c. 212°). Obtained by boiling  $C_6H_4ClCHBr_2$  [48°] (10 pts.) with lead nitrate (4 pts.) and water (100 pts) for three days, in presence of  $CO_2$  (Jackson a. White, Am. J. 3, 31; N. Am. A. 15, 268; B. 11, 1042). Formed by boiling  $C_6H_4ClCH_2Cl$  with aqueous lead nitrate. Formed also by passing chlorine into benzoic aldehyde containing iodine (Beilstein a. Kuhlberg, A. 147, 339). Long needles; may be sublimed. Sol. alcohol, ether,  $CS_2$ , and  $HOAc$ , sl. sol. water. Absorbs oxygen from the air. Forms a crystalline compound with  $NaHSO_4$ .

Di-chloro-benzoic aldehyde  $C_6H_3Cl_2CHO$  [5:2:1]. [58°]. (230°-233°). Preparation not given. White crystals. On oxidation it gives di-chloro-benzoic acid [152°] (Gnehm, B. 17, 752).

Di-chloro-benzoic aldehyde  $C_6H_3Cl_2CHO$  [6:2:1]. [68°]. Formed by heating  $C_6H_3Cl_2CHCl_2$  with water at 200° (Beilstein a. Kuhlberg, A. 152, 224). Slender needles; volatile with steam; sl. sol. hot water. Attacks the eyes. Combines with  $NaHSO_4$ . Oxidises to di-chloro-benzoic acid [128°].

(B)-Di-chloro-benzoic aldehyde  $C_6H_3Cl_2CHO$  [4:2:1]. [71°]. (c. 233°). Formed by the action of conc.  $H_2SO_4$  on  $C_6H_3Cl_2CHCl_2$ . The aldehyde is separated by means of the double compound with sodium bisulphite (See lig. A. 237, 167). White needles (from alcohol). Oxidation with permanganate yields (B)-dichloro-benzoic acid [159°]. When heated with  $Ac_2O$  and  $NaOAc$  it forms (B)-di-chloro-cinnamic acid [228°].

Tri-chloro-benzoic aldehyde  $C_6H_2Cl_3CHO$  [113°]. Formed by heating  $C_6H_2Cl_3CHCl_2$  [281°] with water at 250° (B. a. K.; Seelig, B. 18, 420; A. 237, 148). Very slender needles;

insol. boiling water, v. sol. alcohol; volatile with steam. Conc.  $H_2SO_4$  and  $KNO_3$  form tri-chloro-nitro-benzoic acid [222°] and an aldehyde [124°].

Tri-chloro-benzoic aldehyde  $C_6H_2Cl_3CHO$  [4:3:21] [90°]. From penta-chloro-toluene  $C_6H_2Cl_5$ ,  $CHCl_3$  [84°] (Seelig). Gives on oxidation tri-chloro-benzoic acid [139°].

**CHLORO-BENZONITRILE** v. **NITRILE** OF **CHLORO-BENZOIC ACID**.

**CHLORO-BENZOPHENONE**  $C_6H_4Cl.CO.C_6H_5$ . *Phenyl chloro-phenyl ketone*. [76°]. (above 300°). rom chloro-benzene, benzoic acid, and  $P_2O_5$ . Kollarits a. *Merz*, B. 6, 547. Flat needles (from ether-alcohol); v. sol. ether, sl. sol. cold alcohol and ligroin.

**CHLORO-o-BENZOYL-BENZOIC ACID**  $C_6H_4Cl.O.CO.C_6H_4.CO_2H$  [2:4or5:1]. *Chloro-benzophenone carboxylic acid*. [171°]. From chloro-phthalic anhydride [97°], benzene, and  $AlCl_3$  (Grahe a. *Rde*, C. J. 49, 531; A. 238, 239). Minute monoclinic prisms; v. sol. ether and alcohol, sl. sol.  $CS_2$ , v. sl. sol. light petroleum. Conc.  $H_2SO_4$  converts it into chloro-anthraquinone [204°].

Di-chloro-o-benzyl-benzoic acid  $C_6H_3Cl_2.CO.C_6H_4.CO_2H$ . [159°]. From (8)-di-chloro-phthalic anhydride [150°], benzene, and  $AlCl_3$  (Le Royer, A. 238, 356). Needles (from dilute alcohol).

Tetra-chloro-o-benzyl-benzoic acid  $C_6H_2Cl_4.CO.C_6H_4.CO_2H$ . [200°]. From tetra-chloro-phthalic anhydride, benzene, and  $AlCl_3$  (Kiroher, A. 238, 358). White needles; sl. sol. cold benzene, v. e. sol. alcohol, insol. water. Cannot be distilled or sublimed.

**Reactions**.—1. *Soda-fusion* gives benzoic acid. 2.  $H_2SO_4$  and  $PCl_5$  give tetra-chloro-anthraquinone.—3.  $HI$  gives tetra-chloro-benzyl-benzoic acid.

**Salts**.— $NaA'$  4aq. S. 1.7 at 20°.— $KA'$  1½aq. — $CuA'$  2aq. — $CuA'$ ,  $CuO$ .

**Ethers**:  $EtA'$  [90°].— $MeA'$  [92°].

**Chlorides** [183°]. Needles.

**CHLORO-BENZOYL CHLORIDE** v. *Chloride* of **CHLORO-BENZOIC ACID**.

**CHLORO-DIBENZYL** v. **CHLORO-DI-PHENYL**.

**ETHANE**.

**p-CHLORO-BENZYL ACETATE**  $C_6H_4Cl.O.CO.C_2H_5$  [4:1]  $C_6H_4Cl.CH_2.OAc$ . [240°]. From  $C_6H_4Cl.CH_2Cl$  and  $KOAc$  in boiling alcohol (Beilstein a. Kuhlberg, A. 147, 344).

Di-chloro-benzyl acetate  $C_6H_3Cl_2.CH_2.OAc$ . [259°]. Similarly prepared from  $C_6H_2Cl_4.CH_2Cl$  (B. a. K.).

**CHLORO-BENZYL-ACETO-ACETIC ETHER**  $C_6H_4Cl_2.CO_2CH(OH)CH_3$  [41°]. Formed, together with an isomeride [72°] possibly  $CH_3.CO.OO(CH_2Ph).CO_2Et$ , by mixing aceto-acetic ether with benzoic aldehyde and saturating with  $HCl$  (v. vol. i. 24).

**p-CHLORO-BENZYL ALCOHOL**  $C_6H_4Cl.OH$  [68°] (B. a. K.); [71°] (J. a. F.). Obtained by heating p-chloro-benzyl acetate (v. *supra*) with alcoholic  $NH_3$  at 160° (Beilstein a. Kuhlberg, A. 147, 344; Neuhoft, Z. [2] 3, 467). Prepared by boiling p-chloro-benzyl chloride  $C_6H_4Cl.CH_2Cl$  with water (Jackson a. Field, *Am.* 2, 88; P. *Am.* A. 14, 56). Needles (by sublimation or from water); may be distilled. Sol. hot water, alcohol, and ether. Chromic mixture oxidises it to p-chloro-benzoic acid [388°].

Di-chloro-benzyl alcohol  $C_6H_3Cl_2.CH_2OH$ . [77°]. From the acetate (v. *supra*) by heating with alcoholic ammonia at 180° (B. a. K.). Needles; v. sl. sol. water.

Tri-chloro-benzyl alcohol  $C_6H_2Cl_3.CH_2OH$ . From tri-chloro-benzyl chloride  $C_6H_2Cl_3.CH_2Cl$  and alcoholic  $KOAc$  at 160°. Crystalline (Beilstein a. Kuhlberg, A. 152, 241).

Tetra-chloro-benzyl alcohol  $C_6HCl_4.CH_2OH$ . From  $C_6HCl_4.CH_2Cl$ , alcohol, and  $KOAc$  at 180°; crystallised from water (B. a. K.).

Penta-chloro-benzyl alcohol  $C_6Cl_5.CH_2OH$ . [193°]. From  $C_6Cl_5.CH_2Cl$ , alcohol, and  $KOAc$  at 200° (B. a. K.). White needles (from benzene-alcohol); insol. water, sl. sol. boiling alcohol.

**p-CHLORO-BENZYLAMINE**  $C_6H_4Cl.NH_2$  i.e.  $C_6H_4Cl.CH_2.NH_2$ . p-Chloro-benzyl chloride (1 vol.) heated with alcoholic ammonia (2 vols.) at 100° forms  $(C_6H_4Cl.CH_2)_2NH_2$ ,  $(C_6H_4Cl.CH_2)_3NH$  and  $(C_6H_4Cl.CH_2)_4N$ . Their hydrochlorides may be separated by crystallisation from alcohol (Berlin, A. 251, 187; Jackson a. Field, *Am.* 2, 94; P. *Am.* A. 14, 56). Colourless oil; sol. ether.

**Salts**.— $B'HCl$ : [241°]; narrow plates, sol. water and alcohol.— $B'_2H_2PtCl_4$ : yellow needles.  $B'HBr$ : [230°]; decomposed by melting.— $B'_2H_2CO_3$ : [116°]; plates (from water) or needles (from alcohol).

**Di-p-chloro-di-benzyl-amine**  $(C_6H_4Cl.CH_2)_2NH$ . [29°]. From chloro-benzyl bromide and alcoholic  $NH_3$  (Jackson a. Field, *Am.* 2, 90; B. 11, 904). White blades; insol. water, sol. alcohol, ether, benzene, and  $CS_2$ .

**Salts**.— $B'HCl$ : [288°]; plates, sol. water and alcohol, insol. ether.— $B'_2H_2PtCl_4$ : yellow scales, sl. sol. boiling water, insol. alcohol.— $B'HBr$ : [280°–290°], melting with decomposition. Scales, sl. sol. water, insol. ether.

(8)-Di-chloro-di-benzyl-amine  $(C_6H_3Cl_2.CH_2)_2NH$ . This base occurs, together with the two following, among the products of the reaction of alcoholic  $NH_3$  on crude chloro-benzyl chloride (Berlin, A. 151, 141).— $B'HCl$ : [228°].  $B'HBr$ : [224°].— $B'HI$ : [215°].— $B'HNO_3$ : [204°].

(γ)-Di-chloro-di-benzyl-amine  $(C_6H_3Cl_2.CH_2)_2NH$ . **Salts**.— $B'HCl$ : [220°].— $B'HBr$ : [212°].— $B'HI$ : [187°].— $B'HNO_3$ : [193°].

(δ)-Di-chloro-di-benzyl-amine  $(C_6H_3Cl_2.CH_2)_2NH$ . **Salts**.— $B'HCl$ : [222°].— $B'HBr$ : [199°].— $B'HI$ : [218°].— $B'HNO_3$ : [179°].

Tri-p-chloro-tri-benzyl-amine  $(C_6H_2Cl_3.CH_2)_3N$ . [79°]. From p-chloro-benzyl bromide and alcoholic  $NH_3$  (J. a. F.). Needles; sol. hot alcohol, ether, benzene, and  $CS_2$ .

**Salts**.— $B'HCl$  2aq: [196°].— $B'_2H_2PtCl_4$ : pale orange plates, insol. water, alcohol, and ether.

**TETRA-CHLORO-o-BENZYL-BENZOIC ACID**  $C_6HCl_4.CH_2.CO_2H$ . *Tetra-chloro-di-phenyl-methane iso-carboxylic acid*. [157°]. From  $C_6HCl_4.CO_2Cl$ ,  $CO_2H$  and conc.  $HI$  at 180° (Kiroher, A. 238, 348). Hair-like needles (from dilute alcohol). Insol. water, v. sol. alcohol.

**Salts**.— $NaA'$  4aq.— $AgA'$ . **CHLORO-BENZYL BROMIDE** v. **CHLORO-BROMO-TOLUENE**.

**CHLORO-BENZYL CHLORIDE** v. **DI-CHLORO-TOLUENE**.

**CHLORO-BENZYL CYANIDE** v. **Nitrile** of **CHLORO-PHENYL-ACETIC ACID**.

**p-CHLORO-BENZYL ETHYL OXIDE**

$C_6H_4ClCH_2O.C_2H_5$ . (217°) (Sintenis, A. 161, 385); (215°-225°) (Jackson a. White, Am. 2, 170); (226°) (Errera, G. 17, 206). From *p*-chloro-benzyl chloride (acetate or bromide) and alcoholic KOH (Naquet, A. Suppl. 2, 251). Liquid, with fruity odour; decomposed by heating above its boiling-point into *p*-chloro-benzoic aldehyde and ethane (E.).

**o-CHLORO-BENZYLIDENE-ANILINE**

$C_6H_5.N.COCl.C_6H_4$ . *Benzanilide-imide-chloride*. [41°]. Formed by isomeric change of the first formed oxim-chloride ( $C_6H_5.C:NCl$ ) by the action of  $PCl_5$  or  $POCl_3$  upon benzophenone-oxim ( $C_6H_5.C:NOH$ ). Colourless rhombic tables (Beckmann, B. 19, 989).

**CHLORO-BENZYLIDENE CHLORIDE v. CHLORO-TOLUENE**

**o-CHLORO-BENZYLIDENE-MALONIC ACID**  
 $C_6H_4ClO$ , i.e.  $C_6H_4Cl.CH.CO_2H$ . [192°]. Formed by heating malonic acid with *o*-chloro-benzoic aldehyde and HOAc for some hours at 100° (Stuart, C. J. 53, 141). Decomposes on melting into  $CO_2$  and chloro-cinnamic acid. Boiling water splits it up into *o*-chloro-benzoic aldehyde and malonic acid.

**o-CHLORO-BENZYLIDENE-(a)-NAPHTHYLAMINE**  $C_{10}H_7ClCl.N.C_6H_4$ . [60°]. From benzoyl-(a)-naphthylamine and  $PCl_5$  (Just, B. 19, 979).

**o-CHLORO-BENZYLIDENE-(b)-NAPHTHYLAMINE** [68°]. Similarly prepared (J.). Leaflets; slowly converted into benzoyl-(b)-naphthylamine on exposure to the air.

**CHLORO-BENZYLIDENE-PHTHALIMIDINE**  
 $C_{10}H_7ClNO$ . [332°]. From benzylidene-phthalimidine and  $PCl_5$  (Gabriel, B. 18, 1260). Needles (from alcohol).

**o-CHLORO-BENZYLIDENE-o-TOLUIDINE**  
 $C_{10}H_7ClN$  i.e.  $C_6H_4Me.N.COCl.C_6H_4$ . *Benzoyl-o-toluidine-imide-chloride*. Formed by the action of  $PCl_5$  upon benzoyl-*o*-toluidine. Water regenerates benzoyl-*o*-toluidine. The compound was not obtained in a pure state. With sodio-malonic ether it gives *o*-tolyl- $\beta$ -imido-benzyl-malonic ether  $C_6H_4.C(NC_6H_4).CH(CO_2Et)_2$  (Just, B. 19, 982).

**o-Chloro-benzylidene-*m*-toluidine**  
 $C_{10}H_7ClN$  i.e.  $C_6H_4Me.N.COCl.C_6H_4$ . Formed by the action of  $PCl_5$  upon benzoyl-*m*-toluidine. Not obtained in a pure state. By the action of sodio-malonic ether it yields *m*-tolyl- $\beta$ -imido-benzyl-malonic ether  $C_6H_4.C(NC_6H_4).CH(CO_2Et)_2$  (Just, B. 19, 983).

**o-Chloro-benzylidene-*p*-toluidine**  
 $C_{10}H_7Me.N.COCl.C_6H_4$ . [52°]. Formed by gently warming benzoyl-*p*-toluidine with  $PCl_5$ . Large clear prismatic crystals. By boiling with water or alcohol it is reconverted into the benzoyl-*p*-toluidine. With *p*-toluidine it yields di-*p*-tolyl-benzamidine  $C_6H_4.C(NC_6H_4).NHC_6H_4$ . With sodio-malonic ether it gives *p*-tolyl- $\beta$ -imido-benzyl-malonic ether  $C_6H_4.C(NC_6H_4).CH(CO_2Et)_2$  (Just, B. 19, 979).

**CHLORO-BENZYL-MALONIC ETHER**  
 $C_6H_4.CH_2.COCl(CO_2Et)_2$ . (305°). S.G.  $\frac{1}{2}$  1.150. Prepared by the action of benzyl chloride (26 pts.) on chloro-malonic ether (38.8 pts.) and NaOEt (from 4.6 pts. Na and 70 pts. alcohol) (Conrad, A. 209, 243; B. 18, 2159). Liquid. Decomposed by KOH into alcohol, benzyl-tar-

tronic acid  $C_6H_4.CH_2.C(OH)(CO_2H)_2$ , and a little cinnamic acid.

*Amide*  $C_6H_4Cl(CO.NH_2)_2$ . (o. 80°). White needles. Sol. alcohol, insol. water. (Bischoff a. Emmert, B. 15, 1112).

**p-CHLORO-BENZYL MERCAPTAN**  $C_6H_4ClS$  i.e. [4.1]  $C_6H_4ClCH_2.SH$ . [20°] (J. a. W.). From *p*-chloro-benzyl bromide (or chloride) and alcoholic KHS (Beilstein, A. 116, 347; 147, 346; Jackson a. White, Am. 2, 167; P. Am. A. 14, 312). Nauseous liquid or white crystals. Mixes with alcohol, ether, benzene, and  $CS_2$ .—( $C_6H_4ClS$ ).Hg: from the mercaptan and ppd. HgO; needles; insol. water, a. sol. ether and alcohol.

**DI-p-CHLORO-DI-BENZYL SULPHIDE**  
 $C_{12}H_{10}Cl_2S$  i.e.  $(C_6H_4ClCH_2)_2S$ . [42°]. From *p*-chloro-benzyl bromide and alcoholic  $Na_2S$  (Jackson a. White, P. Am. A. 14, 312; Am. 2, 166; C. J. 18, 1217). Thick needles, insol. water, v. sol. alcohol, ether, benzene and  $CS_2$ .

**Di-*p*-chloro-di-benzyl disulphide**  $C_{12}H_{10}Cl_2S_2$  i.e.  $(C_6H_4ClCH_2)_2S_2$ . [59°]. From *p*-chloro-benzyl bromide and alcoholic  $Na_2S_2$  (J. a. W.). Flat needles, with disagreeable smell. V. sol. alcohol, HOAc, ligroin, ether, benzene, and  $CS_2$ .

**p-CHLORO-BENZYL SULPHOCYANIDE**  
 $C_6H_4ClCH_2S.CN$ . [17°]. Prepared by boiling an alcoholic solution of *p*-chloro-benzyl bromide with KCNS (Jackson a. Field, Am. 2, 91). White flat needles.

**DI-p-CHLORO-DI-BENZYL-SULPHONE**  
 $C_{12}H_{10}Cl_2SO_2$  i.e.  $(C_6H_4ClCH_2)_2SO_2$ . [165°]. Formed, together with  $C_6H_4ClCH_2SO_3H$ , by the action of  $K_2SO_8$  on *p*-chloro-benzyl chloride (Henninger a. Vogt, A. 166, 374). Prepared by oxidising *p*-chloro-benzyl sulphide with  $CrO_3$  (Jackson a. White, Am. 2, 167; P. Am. A. 14, 312). Very small needles (from alcohol); insol. water, sol. alcohol, ether, HOAc, and  $CS_2$ .

Isomerides [149°] and [185°] are formed when crude chloro-benzyl chloride is used (H. a. V.).

**CHLORO-BENZYL-SULPHONIC ACID v. CHLORO-TOLUENE SULPHONIC ACID**

**DI-p-CHLORO-DI-BENZYL DI-SULPHOXIDE**  $(C_6H_4ClCH_2)_2S_2O_2$ . [120°]. Obtained by oxidising di-*p*-chloro-di-benzyl disulphide with  $CrO_3$  in HOAc (Jackson a. White, Am. 2, 169; P. Am. A. 14, 315). Waxy solid, becoming crystalline; insol. water, v. sol. alcohol and ether.

**DI-CHLORO-BETORCIN**  $C_6Cl_2Me_2(OH)_2$ . [142°]. Prepared by adding tetra-chloro-betorcin in small portions to boiling hydric iodide (16 p.a.). Crystallised from light petroleum (50 pts.) (Stenhouse a. Groves, C. J. 37, 395). Colourless needles. Sol.  $CS_2$ , benzene and ether.

**Tetra-chloro-betorcin**  $C_6Cl_4Me_2(OCl)_2$ . [108°]. Prepared by adding a solution of betorcin to a slight excess of chlorine hydrate (ice and water saturated with Cl). The crystals which separate after 12 hours are recrystallised from light petroleum. The yield is quantitative (Stenhouse a. Groves, C. J. 37, 399).

*Properties*.—Large white prisms. V. sol. benzene and ether, insol. water.

**CHLORO-BROMAL v. CHLORO-DI-BROMO-ACETIC ALDEHYDE**

**CHLORO-BROMALIDE**  $C_2H_3Cl_2BrO$ . [123°]. Colourless prisms. Formed by heating di-chloro-

bromo-acetic aldehyde with  $\text{H}_2\text{SO}_4$  (Jacobsen a. Neumeister, *B.* 15, 600).

**CHLORO-BROMANILIC ACID** v. CHLORO-BROMO-DI-OXY-QUINONE.

#### CHLORO-BROMO-ACETIC ACID

$\text{CHClBr} \cdot \text{CO}_2\text{H}$ . [201°]. Prepared by heating chloro-acetic acid (1 mol.) with bromine (1 mol.) at 160° (Cech a. Steiner, *B.* 8, 1174). Pungent liquid; attacks the skin. Its salts are v. sol. water.

*Ethyl ester*  $\text{EtA}'$ . (c. 162°). Smells like peppermint; partially decomposed on boiling.

*Amide*  $\text{CHClBr} \cdot \text{CONH}_2$ : [126°]; needles.

Chloro-di-bromo-acetic acid  $\text{CClBr}_2 \cdot \text{CO}_2\text{H}$ . [89°]. (233°). Formed by oxidation of the corresponding aldehyde with  $\text{HNO}_3$  (Neumeister, *B.* 15, 603). Trimetric plates (from conc.  $\text{HNO}_3$ ). By alkalis it is split up into  $\text{CO}_2$  and chloro-di-bromo-methane.

Salts.— $\text{KA}'$  2aq: glistening soluble prisms.  $\text{PbA}'$  aq, sparingly soluble slender needles.

*Ethyl ether A'Et*: (203°); liquid.

*Amide*  $\text{CClBr}_2 \cdot \text{CONH}_2$ : [127°]; small transparent dimetric tables; v. sol. ether and chloroform, sl. sol. benzene and  $\text{CS}_2$ . Formed together with  $\text{CHClBr}$ , by the action of dry  $\text{NH}_3$  upon di-chloro-tetra-bromo-acetone  $\text{CClBr}_2 \cdot \text{CO} \cdot \text{CClBr}_2$  dissolved in ether (Levy a. Jedlička, *B.* 20, 2320).

Di-chloro-bromo-acetic acid  $\text{CCl}_2\text{Br} \cdot \text{CO}_2\text{H}$ . [64°]. (215°). Formed by oxidation of the corresponding aldehyde with  $\text{HNO}_3$  (Neumeister, *B.* 15, 602). Large prisms. V. sol. water and alcohol. By boiling with alkalis it is split up into di-chloro-bromo-methane and  $\text{CO}_2$ .

Salts.— $\text{KA}'$  3aq: long trimetric prisms.  $\text{NaA}'$  5aq: large tables, sol. water, alcohol, and ether. —  $\text{NH}_4\text{A}'$ : long fine needles.— $\text{PbA}'$  aq: sparingly soluble glistening prisms.

*Ethyl ether A'Et*: (189°); liquid.

*Amide* [189°]: (254°); tables. Sol. alcohol and ether; insol. chloroform.

#### CHLORO-DI-BROMO-ACETIC ALDEHYDE

$\text{CClBr}_2 \cdot \text{CHO}$ . *Chlorobromal*. [149°]. S.G. 1.22793. Prepared by the action of bromine on chloro-acetal  $\text{CH}_2\text{Cl} \cdot \text{CH}(\text{OEt})_2$ . Liquid. By treatment with  $\text{KOH}$  it gives chloro-di-bromo-methane (Jacobsen a. Neumeister, *B.* 15, 600).

• *Hydrate*  $\text{CClBr}_2 \cdot \text{CH}(\text{OH})_2$ . *Chloro-di-bromo-acetic orthoaldehyde*. [52°]; small prisms.

*Alcoholate*  $\text{CClBr}_2 \cdot \text{CH}(\text{OH})(\text{OEt})$ : [46°]; long needles.

Combination with Acetamide [158°].

Di-chloro-bromo-acetic aldehyde  $\text{CCl}_2\text{Br} \cdot \text{CHO}$ . *Bromochloral*. [126°]. S.G. 1.210176. Prepared by the action of bromine on di-chloro-acetal  $\text{CHCl}_2 \cdot \text{CH}(\text{OEt})_2$  (Jacobsen a. Neumeister, *B.* 15, 600). Colourless pungent liquid. On heating with  $\text{H}_2\text{SO}_4$  it gives bromochloralide  $\text{C}_2\text{H}_2\text{Cl}_2\text{Br}_2\text{O}$  [123°].

*Hydrate*  $\text{CCl}_2\text{Br} \cdot \text{CH}(\text{OH})_2$ . *Di-chloro-bromo-acetic orthoaldehyde*. [51°]. Colourless trimetric plates. Sol. water, alcohol, and ether.

*Alcoholate*  $\text{CCl}_2\text{Br} \cdot \text{CH}(\text{OH})(\text{OEt})$ : [43°]; slender needles.

#### CHLORO-BROMO-ACETO-ACETIC ETHER

$\text{C}_2\text{H}_3\text{ClBrO}_2$ . From chloro-aceto-acetic ether and Br; or from bromo-aceto-acetic ether and Cl (Mervin, *A.* 245, 62). Oil. NaOEt gives bromo-acetic ether.

#### Chloro-di-bromo-aceto-acetic ether

$\text{C}_2\text{H}_2\text{Cl}_2\text{Br}_2\text{O}_2$ . From di-bromo-aceto-acetic ether and Cl in diffused daylight (M.). NaOEt forms chloro-bromo-acetic ether (162°).

#### Di-chloro-bromo-aceto-acetic ether

$\text{C}_2\text{H}_2\text{Cl}_3\text{BrO}_2$ . From bromo-aceto-acetic ether and Cl (M.). NaOEt forms di-chloro-acetic ether.

#### Di-chloro-di-bromo-aceto-acetic ether

$\text{C}_2\text{H}_2\text{Cl}_4\text{Br}_2\text{O}_2$ , i.e.  $\text{CHBr}_2 \cdot \text{CO} \cdot \text{CCl}_2 \cdot \text{CO} \cdot \text{Et}$  (?) S.G. 1.21956. Formed by bromination of di-chloro-aceto-acetic ether. Oil. On saponification by heating with HCl it yields di-chloro-di-bromo-acetone (Conrad a. Guthzeit, *B.* 16, 1551).

#### CHLORO-BROMO-ACETONE $\text{C}_2\text{H}_3\text{ClBrO}$ i.e.

$\text{CH}_2\text{Cl} \cdot \text{CO} \cdot \text{CH}_2\text{Br}$  or  $\text{CH}_2\text{Cl} \cdot \text{CH}(\text{Br}) \cdot \text{CO}$ . [35°]. (c. 179°). Obtained from epichlorhydrin

$\text{CH}_2\text{Cl} \cdot \text{CH}_2 \cdot \text{CH}_2$  by treatment with HBr and oxidation of the resulting  $\text{CH}_2\text{Cl} \cdot \text{CH}(\text{OH}) \cdot \text{CH}_2\text{Br}$  (Theegarten, *B.* 6, 897, 1276). Pungent crystals, sl. sol. water; v. sol. alcohol and ether. Forms a crystalline compound with  $\text{NaHSO}_4$  (Theegarten; cf. Cloez, *A. Ch.* [6] 9, 145).

Chloro-tri-bromo-acetone  $\text{C}_2\text{H}_2\text{Br}_3\text{ClO}$ . [50°]. Prepared by heating dichloro-dibromo-acetone with HBr; or dichlorhydrin (1 mol.) with bromine (3 mols.) and water at 110° (Claus a. Lindhorst, *B.* 13, 1210). Trimetric prisms:  $a:b:c = 7124:1:2$ .

Chloro-tri-bromo-acetone  $\text{C}_2\text{H}_2\text{ClBr}_3\text{O}$ . *Tri-bromo-epichlorhydrin*. Prepared by treating epichlorhydrin (1 mol.) with bromine (1 mol.) at 100°. Pungent liquid; heavier than water; cannot be distilled even *in vacuo*. On shaking with water it forms a hydrate  $\text{C}_2\text{H}_2\text{ClBr}_3\text{O} \cdot 4\text{aq}$  [55°] (Grimaux a. Adam, *Bl.* [2] 33, 257; cf. Cloez, *A. Ch.* [6] 9, 145).

Chloro-tri-bromo-acetone  $\text{C}_2\text{H}_2\text{ClBr}_3\text{O}$  i.e.  $\text{CBr}_2 \cdot \text{CO} \cdot \text{CH}_2\text{Cl}$ . (215°). S.G. 2.27. From chloro-acetone and bromine at 100° (Cloez). Pungent liquid. Forms hydrates  $\text{C}_2\text{H}_2\text{ClBr}_3\text{O} \cdot 4\text{aq}$  (from water) and  $\text{C}_2\text{H}_2\text{ClBr}_3\text{O} \cdot \text{aq}$  (from alcohol). Cold aqueous ammonia forms bromoform and chloro-acetamide.

#### Di-chloro-di-bromo-acetone $\text{C}_2\text{H}_2\text{Cl}_2\text{Br}_2\text{O}$ i.e.

$\text{CHBr} \cdot \text{Cl} \cdot \text{CH} \cdot \text{CBrCl}$  or  $\text{CHBrCl} \cdot \text{CO} \cdot \text{CHBrCl}$ . [8°]. (135°) at 40 mm. From di-chloro-acetone (derived from epichlorhydrin) and bromine (Cloez). Does not combine with  $\text{NaHSO}_4$ . With water it forms long prisms of the hydrate  $\text{C}_2\text{H}_2\text{Cl}_2\text{Br}_2\text{O} \cdot 4\text{aq}$  [54°]. Does not give off a chloro-bromo-methane when treated with ammonia.

#### Di-chloro-di-bromo-acetone $\text{C}_2\text{H}_2\text{Cl}_2\text{Br}_2\text{O}$ i.e.

$\text{CBr}_2 \cdot \text{Cl} \cdot \text{CH} \cdot \text{CHCl}$  or  $\text{CBr}_2 \cdot \text{Cl} \cdot \text{CO} \cdot \text{CH}_2\text{Cl}$  (141°) at 20 mm. Prepared by heating dichlorhydrin (1 mol.) with bromine (3 mols.) and the volume of water to 110° until the colour of the Br has gone; the yield is theoretical (Claus a. Lindhorst, *B.* 13, 1209; cf. Carius, *A.* 155, 88; Grimaux a. Adam, *Bl.* [2] 32, 14; Cloez, *loc. cit.*). Forms a hydrate  $\text{C}_2\text{H}_2\text{Cl}_2\text{Br}_2\text{O} \cdot 4\text{aq}$ , [56°], (140°-150°) at 20 mm. Not identical with the preceding (C).

Di-chloro-di-bromo-acetone  $\text{CHCl}_2\text{COCHBr}_2$  (120°) at 25 mm. Formed by the action of bromine on ordinary di-chloro-acetone or Barbaglia's di-chloro-acetone (170°) (Cloeze). It forms unstable hexagonal tables of  $\text{C}_2\text{H}_2\text{Cl}_4\text{Br}_2\text{O}$  4aq. Ammonia forms no chloro-bromo-methane.  $\text{HgCl}_2$  gives tetra-chloro-acetone.

Di-chloro-di-bromo-acetone  $\text{C}_2\text{H}_2\text{Cl}_4\text{Br}_2\text{O}$  or  $\text{CHCl}_2\text{COCHBr}_2$  (?) Formed by heating di-chloro-di-bromo-aceto-acetic ether with  $\text{HCl}$  (Conrad a. Guthzeit, *B.* 16, 1552). Colourless pungent liquid. Forms a hydrate  $\text{C}_2\text{H}_2\text{Cl}_4\text{Br}_2\text{O}$  4aq crystallising in large colourless six-sided tables. Is perhaps identical with the preceding.

Di-chloro-tetra-bromo-acetone  $\text{CClBr}_2\text{COCClBr}_2$  (79°). Formed by the action of bromine upon *p*-di-chloro-*p*-di-oxy-quinone (chloranilic acid)  $\text{C}_6\text{Cl}_2(\text{OH})_2$ . Transparent monoclinic crystals (from acetic acid). Heated with baryta-water it yields chloro-di-bromo-methane  $\text{CHClBr}_2$ . Dry  $\text{NH}_3$  gas converts it into chloro-di-bromo-acetamide  $\text{CClBr}_2\text{CONH}_2$  and chloro-di-bromo-methane. With phenyl-hydrazine it gives a mixture of chloro- and bromo-benzene (Levy a. Jedlička, *B.* 20, 2319; cf. Stenhouse, *A. Suppl.* 8, 17).

Tri-chloro-bromo-acetone  $\text{C}_2\text{H}_2\text{Cl}_3\text{BrO}$  i.e.  $\text{COClCOCHBr}$  (190°). From tri-chloro-acetone and bromine at 100°. Very hygroscopic, forming hexagonal tables of the hydrate  $\text{C}_2\text{H}_2\text{Cl}_3\text{BrO}$  4aq [48°]. With ammonia it forms chloroform and bromo-acetamide (Cloeze).

TRI-CHLORO-*o*-DI-BROMO-ACETYL-PRO-PIONIC ACID  $\text{C}_2\text{HCl}_2\text{Br}_2\text{O}_2$  i.e.  $\text{CCl}_2\text{COCHBrCHBrCO}_2\text{H}$  [98°]. From tri-chloro-acetyl-acrylic acid and  $\text{Br}$  in chloroform (Kekulé a. O. Strecker, *A.* 223, 188). Volatile with steam; may be sublimed; insol. cold water. Boiling lime-water splits it up into chloroform and inactive tartaric acid.

CHLORO-BROMO-ACRYLICACID  $\text{C}_2\text{HClBrCO}_2\text{H}$  i.e.  $\text{CBrClCHCO}_2\text{H}$  (?) [70°]. S. 5-75 at 20°. Prepared by the action of  $\text{HCl}$  on bromo-propionic acid at 0° (Mabery a. Lloyd, *Am.* 3, 127; Hill, *B.* 12, 660). Needles or prisms; may be sublimed.  $\text{C}_2\text{H}_2$  sol. alcohol and ether. Chlorine forms tri-chloro-bromo-propionic acid [84°] (Mabery, *Am.* 9, 1).

Salts.— $\text{KA}'$ .— $\text{BAa}'$ , 2aq: flattened prisms. S. 14-15 at 20°.  $\text{CaA}'$ , 4aq: needles; v. s. sol. hot water.— $\text{AgA}'$ .

(a) Chloro-di-bromo-acrylic acid  $\text{C}_2\text{HClBrCO}_2\text{H}$  i.e.  $\text{CBrClCO}_2\text{H}$  (?) [104°]. S. 5-7 at 20°. Prepared by the action of  $\text{ClBr}$  in chloroform on bromo-propionic acid in the cold (Mabery a. Lloyd, *Am.* 6, 167). Triclinic prisms (from  $\text{CS}_2$ ); v. sol. hot water,  $\text{CS}_2$ , and chloroform.

Salts.— $\text{AgA}'$ : trimetric plates (from water); not affected by light.— $\text{CaA}'$ , 2½aq: branching needles.— $\text{BAa}'$ , 3aq: flat prisms. S. 26 at 20°.

(b) Chloro-di-bromo-acrylic acid  $\text{C}_2\text{HClBrCO}_2\text{H}$  [99°]. S. 2-5 at 20°. From chloro-tri-bromo-acrylic acid by adding baryta-water in the cold till alkaline (M. a. L.). Prisms (from  $\text{CS}_2$ ); v. sol. alcohol, ether, and hot water.— $\text{BAa}'$ , 3aq: slender prisms. S. 35 at 20°.— $\text{CaA}'$ , 4aq: branching needles.

Di-chloro-bromo-acrylic acid  $\text{C}_2\text{HCl}_2\text{CO}_2\text{H}$  i.e.  $\text{CCl}_2\text{CHCO}_2\text{H}$  (?) [78°-80°]. S. 6-9 at

20°. Obtained by the action of cold baryta-water on di-chloro-di-bromo-propionic acid obtained from *o*-di-bromo-acrylic acid and chlorine (Mabery, *Am.* 9, 8). Prisms; v. sol. alcohol and ether: sl. sol. cold  $\text{CS}_2$ .

Salts.— $\text{KA}'$ : slender needles.  $\text{O}$   $\text{AgA}'$ : slender needles.— $\text{BAa}'$ , 3aq: trimetric plates.— $\text{CaA}'$ , 4aq: pearly needles.

Di-chloro-bromo-acrylic acid  $\text{C}_2\text{HCl}_2\text{CO}_2\text{H}$  i.e.  $\text{CClBrCHBrCO}_2\text{H}$  (?) [85°]. S. 2-6 at 20°. Obtained by the action of cold baryta-water (1 mol.) on di-chloro-di-bromo-propionic acid (1 mol.) that has been prepared from bromine and *o*-di-chloro-acrylic acid (M.). Prisms; v. sol. alcohol and ether, m. sol.  $\text{CS}_2$ . This acid is possibly identical with the preceding.

Salts.— $\text{KA}'$ : pearly needles.— $\text{AgA}'$ : slender needles.— $\text{BAa}'$ , 3aq: trimetric plates.— $\text{CaA}'$ , 4aq: jagged plates.

$\text{O}$  CHLORO-BROMO-ALDEHYDE v. CHLORO-BROMO-ACETIC ALDEHYDE.

$\omega$ -DI-CHLORO-*m*-BROMO-AMIDO-ACETO-PHENONE [5:2:1]  $\text{C}_6\text{H}_3\text{Br}_2(\text{NH}_2)\text{COCHCl}_2$  [110°-120°]. Formed by boiling *o*-tri-bromo-amido-acetophenone with  $\text{HCl}$  (Baeyer a. Bloem, *B.* 17, 967). Sublimable. Fine felted orange needles or long flat prisms. V. sol. alcohol, sl. sol. water. By boiling with dilute  $\text{NaOH}$  and exposure to the air it yields bromo-indigo.

CHLORO-BROMO-ANILINE  $\text{C}_6\text{H}_4\text{ClBr}(\text{NH}_2)$  [3:4:1]. [69°]. Formed, together with *p*-bromo-aniline, by the action of  $\text{Jn}$  and  $\text{HCl}$  on *p*-bromo-nitro-benzene (Hübner a. Alsberg, *A.* 156, 312; Fittig a. Büchner, *A.* 188, 14). Formed also by chlorinating *p*-bromo-aniline. Prisms; volatile with steam.— $\text{B}'\text{HCl}$ .

Chloro-di-bromo-aniline  $\text{C}_6\text{H}_3\text{Cl}_2\text{Br}(\text{NH}_2)$  [6:4:2:1]. [95°]. Formed by bromination of *o*-chloro-aniline (Langer, *B.* 15, 1065; *A.* 215, 115). Long white needles (from benzoline); v. sol. boiling alcohol and ether.

Chloro-di-bromo-aniline  $\text{C}_6\text{H}_3\text{Cl}_2\text{Br}(\text{NH}_2)$  Formed by brominating *p*-chloro-aniline (Hofmann, *A.* 53, 38). White prisms, which melt in hot water; volatile with steam. Does not form salts.

Chloro-tri-bromo-aniline  $\text{C}_6\text{HClBr}_2(\text{NH}_2)$  [3:2:4:6:1]. [124°]. Formed by bromination of *m*-chloro-aniline by  $\text{Br}$  in dilute  $\text{HCl}$  (Langer, *B.* 15, 1065; *A.* 215, 112). Thin white needles (from alcohol); v. sol. boiling alcohol and ligroin.

Di-chloro-bromo-aniline  $\text{C}_6\text{H}_4\text{Cl}_2\text{Br}(\text{NH}_2)$  [2:6:4:1]. [93-5°]. Formed by chlorinating *p*-bromo-aniline (Fittig a. Büchner, *A.* 188, 22). Does not unite with acids.

Di-chloro-tri-bromo-aniline  $\text{C}_6\text{Cl}_2\text{Br}_2(\text{NH}_2)$  [8:5:2:4:6:1]. [219-5°]. From di-chloro-aniline  $\text{C}_6\text{H}_3(\text{NH}_2)\text{Cl}_2$  [1:3:5] in dilute  $\text{HCl}$  by baryta-water (Langer, *A.* 215, 122). White needles (from alcohol). M. sol. boiling alcohol.

Tri-chloro-di-bromo-aniline  $\text{C}_6\text{Cl}_3\text{Br}(\text{NH}_2)$  [2:4:6:3:5:1]. [238-5°]. From  $\text{C}_6\text{H}_3(\text{NH}_2)\text{Br}$  [1:3:5] in acetic acid by  $\text{Cl}$  (Langer, *A.* 215, 118). White needles (from alcohol).

DI-CHLORO-BROMO-ANTHRACENE  $\text{C}_{14}\text{H}_8\text{Cl}_2\text{Br}$  [168°]. Formed by heating di-chloro-anthracene tetra-bromide at 190° (Schwarzer, *B.* 10, 876). Small greenish-yellow laminae; v. sol. benzene and chloroform.

**Di-chloro-di-bromo-anthracene**  $C_{14}H_8Cl_2Br_2$ , [253°]. From di-chloro-anthracene tetrabromide and alcoholic KOH (S.). Small yellow needles (from benzene); sl. sol. alcohol, v. sol. benzene.

**Di-chloro-tetra-bromo-anthracene**  $C_{14}H_4Cl_4Br_4$ . Formed by the action of alcoholic KOH upon di-chloro-di-bromo-anthracene-tetrabromide (Hammerschlag, B. 19, 1107). Golden-yellow needles. Solid at 380°. V. sl. sol. all solvents. By  $CrO_3$  and acetic acid it is oxidised to tetra-bromo-anthraquinone.

**DI-CHLORO-DI-BROMO-ANTHRACENE-TETRA-BROMIDE**  $C_{14}H_4Cl_4Br_4$ , [212°]. Glistening white needles (from acetic acid). Formed by combination of di-chloro-di-bromo-anthracene with bromine vapour. By alcoholic KOH it is converted into di-chloro-tetra-bromo-anthracene (Hammerschlag, B. 19, 1107).

**m-CHLORO-BROMOBENZENE**  $C_6H_4ClBr$  [1.3]. From *p*-chloro-aniline by bromination and elimination of  $NH_3$  by the diazo-reaction (Körner, J. 1875, 326; G. 4, 305).

**p-Chloro-bromo-benzene**  $C_6H_4ClBr$  [1.4]. [67°]. (196°). From *p*-bromo-aniline by displacement of  $NH_3$  by Cl; or from *p*-chloro-aniline by displacing  $NH_3$  by Br (Griess, Tr. 1864 [3] 702). Also by boiling *p*-chloro-benzene with bromine (Körner, G. 4, 342).

**Chloro-tri-bromo-benzene**  $C_6H_3Cl_2Br_3$  [1.2:4.6]. [80°] (S.); [82°] (L.). **Formation**.—1. By heating the perbromide of tri-bromo-diazo-benzene chloride (from tri-bromaniline) with glacial acetic acid (Silberstein, J. pr. [2] 27, 113).—2. From  $C_6H_3Cl_2Br_3(NH_2)$  [123-5°], alcohol, and amyl nitrite at 100° (Langer, A. 215, 113; B. 15, 1065). **Properties**.—Long satiny needles. Insol. water, sl. sol. cold alcohol and glacial acetic acid, v. sol. hot alcohol, hot glacial acetic acid, ether, benzene and  $CHCl_3$ .

**Di-chloro-di-bromo-benzene**  $C_6H_4Cl_2Br_2$ , [67°] (Garzino, G. 17, 502).

**Di-chloro-tri-bromo-benzene**  $C_6H_3Cl_3Br_3$ , [13:24.6]. [121°]. From  $C_6(NH_2)Cl_3Br_3$  by treatment with amyl nitrite and alcohol (Langer, A. 215, 120; B. 15, 1332). Small thin needles (from alcohol).

**Tri-chloro-di-bromo-benzene**  $C_6H_3Cl_4Br_2$ , [13.5:2.4]. [119°]. From  $C_6(NH_2)Cl_4Br_2$  and amyl nitrite in alcohol (Langer, A. 215, 119). Slender needles. V. sol. boiling alcohol.

**CHLORO-BROMO-BENZOIC ACID**  $C_7H_4ClBrO_2$ , i.e.  $C_7H_3ClBr.CO_2H$  [151°]. S. 26 at 21°. Formed by adding bromine to a hot solution of silver *o*-chloro-benzoate (but not of the free acid) (Pfeifer, B. 5, 656). Slender needles (from water); may be sublimed.—KA' aq. —BA' 3aq.—CaA' 2aq.

**Chloro-bromo-benzoic acid**  $C_7H_3ClBr.CO_2H$ . S. 66 at 21°. From *m*-chloro-benzoic acid and bromine (P.). Slender needles.—BA' 3aq.

**DI-CHLORO-DI-BROMO-BUTANE**  $C_4H_6Cl_2Br_2$ , i.e.  $CH_3CHBr.CHBrCH_2Cl$ . From Br and the di-chloro-butylene derived from crotonic aldehyde (Kokulé, A. 162, 98; Newbury, Am. 5, 113). Decomposes above 100°. Converted by boiling dilute  $K_2CO_3$  into  $C_4H_5ClBrO$  [115°-120°].

**CHLORO-DI-BROMO-BUTYL ALCOHOL**  $C_4H_8Cl_2Br_2O$ . Obtained by the union of bromine with chloro-butanyl (chloro-crotyl) alcohol which is itself got by reduction of tri-chloro-butyl al-

cohol (Garzaroli-Thurnlackh, A. 213, 378).  $HNO_3$  oxidises it to chloro-di-bromo-butyric acid.

#### CHLORO-DI-BROMO-BUTYRIC ACID

$C_4H_6Cl_2Br_2O_2$ , i.e.  $CH_3CHBr.CClBr.CO_2H$  (?) [92°]. From  $\alpha$ -chloro-crotonic acid and Br (Sarnoff, A. 164, 105). Prisms, m. sol. cold, decomposed by hot, water. Distillation, or treatment with zinc and HCl, converts it into chloro-crotonic acid.—PbA'—AgA'.

**Chloro-tri-bromo-butyric acid**  $C_4H_5Cl_3Br_3O_2$ , [140°]. Formed by oxidising the corresponding aldehyde with fuming  $HNO_3$  (Pinner, B. 8, 1324). Small plates.

#### CHLORO-DI-BROMO-BUTYRIC ALDEHYDE

$C_4H_5Cl_2Br_2O$ , i.e.  $CH_3CHBr.CClBr.CHO$ . From Br and  $\alpha$ -chloro-crotonic aldehyde in the cold (Pinner, B. 8, 1322). Oil; with water it slowly forms a solid hydrate or orthoaldehyde  $C_4H_4Cl_2Br_2(OH)_2$ .

**Chloro-tri-bromo-butyric aldehyde**

$C_4H_4Cl_3Br_3O$ . Formed by warming  $\alpha$ -chloro-crotonic aldehyde with bromine (P.). Oil. Forms a hydrate or orthoaldehyde  $C_4H_3Cl_3Br_3(OH)_2$  [78°] crystallising in slender needles.

#### Di-chloro-di-bromo-butyric aldehyde

$CH_3ClCHBr.CClBr.CHO$ , [c.-78°]. From  $\alpha$ -di-chloro-crotonic aldehyde and Br in the cold (Natterer, M. 4, 540). Combines with  $NaHSO_3$ . It forms a crystalline hydrate or orthoaldehyde  $CH_3ClCHBr.CClBr.CH(OH)_2$ , [72°].

#### CHLORO-BROMO-CAMPHOR v. CAMPHOR

**CHLORO-DI-BROMO- $\alpha$ -CUMENE**  $C_{10}H_7Cl_2Br_2$ , [96-5°]. From styryl chloride and Br. Tables (from ether).

#### TRI-CHLORO-BROMO-CYMELE

$*C_9Cl_3Br(CH_3)(C_6H_5)$  (?) [65°]. From sodium tri-chloro-cymene sulphonate and bromine-water (Kelbe, B. 16, 619). Needles.

#### CHLORO-PENTA-BROMO-DECYLENE

$C_{10}H_7Cl_5Br_5$ . From Br and menthyl chloride (Oppenheim, A. 130, 177).

**s-CHLORO-BROMO-ETHANE**  $CH_3Cl.CH_2Br$ . *Ethylene chlorobromide*. (108°). S.G.  $d_{17}^{20}$  1.79;  $d_{17}^{20}$  1.70.

**Formation**.—1. From *s*-chloro-iodo-ethane and Br (Henry, A. 156, 14).—2. From ethylene di-bromide and  $HgCl_2$  (Montgellier a. Girard, Bl. [2] 33, 12).—3. From  $CH_3Cl.CH_2OH$  and Br at 130° (Demole, B. 9, 556).—4. From ethyl bromine by chlorination (Lescœur, Bl. [2] 29, 484).

**Preparation**.—1. Bromine (500 g.) is dissolved in 700 c.c.  $HCl$  mixed with 700 c.c. water, cooled with ice, and treated with chlorine as soon as the temperature of the liquid has fallen to 2°. The chlorine is passed in, with frequent shaking, until the colour of the bromine has disappeared. Ethylene is then passed in, and the oil washed, dried, and distilled. It boils at 107°-109°. If it boils at 109°-111° it contains ethylene bromide (M. Simpson, Pr. 27, 119; J. W. James, J. pr. [2] 26, 380; O. J. 43, 87).—2.  $C_2H_5Br$  is gently warmed with  $SbCl_3$ , the product poured into strong  $HCl$ , and the oil washed with very dilute  $NaOH$  and distilled (Lösner, J. pr. 121, 421; James, C. J. 85, 806).

**Reactions**.—1. Acts upon boiling alcoholic  $KCN$  forming  $C_2H_5Cl(CNS)$ .—2. Alcoholic KOH gives  $KBr$  and chloro-ethylene.

*n*-Chloro-bromo-ethane  $\text{CH}_3\text{CHClBr}$ . *Ethylidene-chloro-bromide*. (83°) (B.); (83° i. v.) (S.). S.G. 1.61 (B.); 1.67.

**Formation.**—1. From bromo-ethylene and conc.  $\text{HClAq}$  at 100° (Reboul, A. 155, 215).—2. By brominating ethyl chloride in sunlight (Staedel, B. 11, 1739; Denzel, A. 195, 193).—3. By chlorinating ethyl bromide (Lescaur, B. [2] 23, 483).

**Properties.**—Oil. Converted by alcoholic KOH into KBr and bromo-ethylene.  $\text{Ag}_2\text{O}$  gives aldehyde.

Chloro-di-bromo-ethane  $\text{CH}_2\text{CBr}_2\text{Cl}$ . (124° i. v.). S.G. 2.2134. A product of bromination of ethyl chloride in sunlight (Staedel, B. 11, 1739; Denzel, A. 195, 196). Liquid. Converted by alcoholic KOH into  $\text{CH}_2\text{CClBr}$ .

Chloro-di-bromo-ethane  $\text{CH}_2\text{BrCHClBr}$ . (163° i. v.). S.G. 2.2688. From chloro-ethylene and Br (Hugo Müller, A. Suppl. 3, 287). From chloro-bromo-iodo-ethane and Br (Henry, B. [2] 42, 263). Also from  $\text{EtCl}$  and Br in sunlight (S.; D.). Oil. Alcoholic KOH gives  $\text{CH}_2\text{CClBr}$ . With  $\text{SbCl}_5$  it gives  $\text{CH}_2\text{BrCHCl}_2$ .

Chloro-di-bromo-ethane  $\text{CH}_2\text{ClCHBr}_2$ . From crude chloro-bromo-iodo-ethane and Br (H.). Alcoholic KOH gives  $\text{CH}_2\text{CBr}_2$  (89°) and  $\text{CH}_2\text{CBrCl}$  (63°).

Chloro-tri-bromo-ethane  $\text{CH}_2\text{BrCClBr}_2$ . (201° i. v.) at 785 mm. S.G. 2.602. Formed by the action of bromine on  $\text{CH}_2\text{CClBr}_2$ , on ethyl chloride, on  $\text{CH}_2\text{BrCHBrCl}$ , or on  $\text{CH}_2\text{CClBr}$  (S.; D.; H.). Gives  $\text{CHBrCClBr}$  with alcoholic KOH.  $\text{SbCl}_5$  forms  $\text{CH}_2\text{BrCCl}_2$ .

Chloro-tetra-bromo-ethane  $\text{CHBr}_2\text{CBr}_2\text{Cl}$ . *Chloro-acetylene tetra-bromide*. (83°). (240°) at 785 mm. S.G. 2.366. From  $\text{EtCl}$  and Br in sunlight (S.; D.). From chloro-acetylene and bromine (Wallach, A. 203, 89). Also from chloro-di-bromo-ethylene and Br (Mabery, Am. 5, 255). Pungent crystals; v. e. sol. alcohol and ether.

Chloro-penta-bromo-ethane  $\text{C}_2\text{ClBr}_4$ . [170°]. Prepared by the action of bromine on chloro-tribromo- and chloro-tetrabromo-ethane (Denzel, B. 12, 2207).

Di-chloro-bromo-ethane  $\text{CH}_2\text{CCl}_2\text{Br}$ . (99° i. v.). S.G. 1.752. Formed by brominating ethylidene chloride in sunlight (S.; D.). Liquid.

Di-chloro-bromo-ethane  $\text{CHCl}_2\text{CH}_2\text{Br}$ . (138°). S.G. 1.859. From  $\text{CHCl}_2\text{CH}_2\text{OH}$  and  $\text{PBr}_3$  (Lacro, C. R. 104, 1186). From  $\text{CHBr}_2\text{CH}_2\text{Br}$  (Henry, C. R. 97, 1491; B. [2] 42, 262), or  $\text{CHClBrCH}_2\text{Br}$  and  $\text{SbCl}_5$ . Converted by alcoholic KOH into  $\text{CH}_2\text{CCl}_2$ .

Di-chloro-bromo-ethane  $\text{CHClBrCHClCl}$ . (140° cor.). S.G. 1.8685; 1.8542. M.M. 10.995 at 21.6°. Formed by gradually adding bromo-ethylene to chloroform through which a current of chlorine is passing (Ferkin, C. J. 45, 535).

According to Lescaur (B. [2] 29, 485) three isomeric di-chloro-bromo-ethanes are formed by chlorinating ethyl bromide, viz.: (1). (187°); S.G. 1.88;—(2). (151°); S.G. 1.998;—(3). (c. 160°); S.G. 2.118.

Di-chloro-di-bromo-ethane  $\text{CHCl}_2\text{CHBr}_2$ . *Acetylene di-chloro-di-bromide*. (195°–200°). S.G. 2.391. From acetylene dibromide and  $\text{SbCl}_5$  in the cold (Sabanejeff, A. 216, 256). Also from acetylene, Br (81 g.), and (120 g. of) aqueous  $\text{HClO}$ . **Reactions.**—1. Converted by Zn and

alcohol into chloro-bromo-ethylene (q. v.).—2. Boiled 6 hours with alcoholic KOAc it forms  $\text{CHBrCCl}_2$  [114°–116°].

*s*-Di-chloro-di-bromo-ethane  $\text{CHClBrCHClBr}$ . *Acetylene di-chloro-di-bromide*. (190°–195°). From bromine and acetylene di-chloride; or from chlorine and acetylene di-bromide (Sa.). Gives, with zinc and alcohol, acetylene dichloride (50°–60°).

Di-chloro-di-bromo-ethane  $\text{CH}_2\text{BrCCl}_2\text{Br}$ . (177°). S.G. 2.270. From  $\text{CH}_2\text{CHCl}_2$  and Br in sunlight (S.; D.).

Di-chloro-tri-bromo-ethane  $\text{CHBr}_2\text{CBr}_2\text{Cl}$ . (215°–220°). From  $\text{CH}_2\text{CHCl}_2$  and Br in sunlight (S.; D.).

Di-chloro-tetra-bromo-ethane  $\text{C}_2\text{Cl}_2\text{Br}_4$ , i. e.  $\text{CBr}_3\text{CClBr}$ . [180°]. Colourless crystals. Prepared by the action of bromine on  $\text{CH}_2\text{BrCCl}_2\text{Br}$  (Denzel, B. 12, 2207).

Tri-chloro-bromo-ethane  $\text{CCl}_2\text{CH}_2\text{Br}$ . (152°). S.G. 1.884. Formed by heating tri-chloro-ethane  $\text{CCl}_3\text{CH}_3$  with bromine at 160°; or by the action of  $\text{SbCl}_5$  on  $\text{CCl}_2\text{BrCH}_2\text{Br}$  or  $\text{CClBr}_2\text{CH}_2\text{Br}$ . Converted by alcoholic KOH into  $\text{CCl}_2\text{CHBr}$  (115°) (Henry, C. R. 98, 370).

Tri-chloro-di-bromo-ethane  $\text{CHBr}_2\text{CCl}_2$ . (200°). S.G. 2.317. From chloral and  $\text{PCl}_5\text{Br}_2$  (Paterno, J. 1871, 512; G. 1, 590).

Tetra-chloro-di-bromo-ethane  $\text{CCl}_2\text{BrCCl}_2\text{Br}$ . *Bromide of per-chloro-ethylene*. S.G. 2.3. From  $\text{C}_2\text{Cl}_4$  and Br in sunshine (Malaguti, A. Ch. [3] 16, 14). Tables (from alcohol). Begins to volatilise at 100° but decomposes at 200° into Br and  $\text{C}_2\text{Cl}_4$ .

Tetra-chloro-di-bromo-ethane  $\text{CCl}_2\text{CClBr}_2$ . From penta-chloro-ethane and Br at 200° (Paterno, G. 1, 593). Also from  $\text{CHBr}_2\text{CHBr}$  and chlorine (Bourgoin, B. [2] 23, 4). Prisms (from alcohol); smells like camphor. May be sublimed, but decomposed by heat into chlorine and  $\text{C}_2\text{Cl}_4\text{Br}_2$ .

CHLORO-BROMO-ETHER *vs* CHLORO-BROMO-DI-ETHYL OXIDE.

*s*-CHLORO-BROMO-ETHYLENE  $\text{C}_2\text{H}_2\text{ClBr}$ , i. e.  $\text{CHClCHBr}$ . *Acetylene chloro-bromide*. (82°). S.G. 1.8157 (P.); 1.779 (S.); 1.747 (S.). Bromine (2 mols.) is slowly added to acetylene chloro-iodide under water. The liberated iodine is removed by  $\text{Na}_2\text{S}_2\text{O}_3$ . The yield is small (Plimpton, C. J. 41, 393). Formed also by treating  $\text{CHClCHBr}_2$  with zinc and alcohol (Sabanejeff, A. 216, 258). Liquid, does not polymerise. With alcoholic KOH it gives off an explosive gas, probably  $\text{C}_2\text{HCl}$ .

Chloro-bromo-ethylene  $\text{CH}_2\text{CClBr}$ . (62°). From chloro-ethylene bromide  $\text{CH}_2\text{BrCHClBr}$  and  $\text{KCy}$  (Hugo Müller, C. J. 17, 420) or alcoholic KOH (Denzel, A. 195, 206). Demple, A. Dürr, B. 11, 1502. Also from chloro-bromo-iodo-ethane (from  $\text{C}_2\text{H}_2\text{Br}$  and  $\text{ICl}$ ) by alcoholic KOH (Henry, B. [2] 42, 263). Pungent odour, readily polymerises, becoming solid. Absorbs dry oxygen forming chloro-acetyl bromide and bromo-acetyl chloride.

Chloro-di-bromo-ethylene  $\text{CHBr}_2\text{CBrCl}$ . (142°) at 785 mm. S.G. 2.275 (S.). From chloro-tri-bromo-ethane  $\text{CH}_2\text{BrCCl}_2\text{Br}$  and alcoholic KOH (Staedel, B. 11, 1740). Formed also by boiling chloro-tri-bromo-propionic acid with baryta-water (Mabery, Am. 5, 255). Liquid.

**Chloro-tri-bromo-ethylene**  $C_2Cl_3Br$ , *i.e.*  $ClBr_2.CBrCl$  (84°). (204°) at 730 mm. Prepared by the action of alcoholic KOH on chloro-tetra-bromo-ethane (Denzel, *B.* 12, 2308).

**Di-chloro-bromo-ethylene**  $CHBr.CCl_2$  (114°-116°). S.G. 1.906. Formed by the action of alcoholic KOH on  $CH_2Br.CBrCl_2$  (Denzel, *A.* 195, 206), or on  $CCl_2.CH_2Br$  (Meny, *C. R.* 98, 370). Also from  $CHBr_2.CHCl_2$  by alcoholic KOAc (Sabanejeff, *A.* 216, 261).

**Di-chloro-di-bromo-ethylene**  $CCl_2.CBr_2$  (c. 194°?). Prepared by the action of alcoholic KOH on di-chloro-tri-bromo-ethane  $CHBr_2.CBrCl_2$  (Staedel, *B.* 11, 1740). Also from  $CCl_2.CClBr_2$  by heating with aniline (Bourgoin, *Bl.* [2] 24, 116). Solidifies below 0°.

**CHLORO-DI-BROMO-DI-ETHYL OXIDE**  $CHClBr.CHBr.OEt$  (170°-180°). From chloro-vinyl ethyl oxide and  $I_2$  (Godefroy, *C. R.* 102, 869).

**Tri-chloro-di-bromo-di-ethyl oxide**  $C_2H_3Cl_3Br_2O$  *i.e.*  $CCl_2Br.CClBr.OEt$  (17°). From tri-chloro-vinyl ethyl oxide and  $Br$  (Busch, *B.* 11, 446). With  $AgOAc$  it gives  $C_2Cl_3Br(OAc)_2.OEt$  (180°-190°).

**Hexa-chloro-tetra-bromo-di-ethyl oxide**  $C_2Cl_6Br_4O$  (36°). Obtained by union of  $Br$  with chloroxethose  $C_2H_4O$ , a substance formed by the action of alcoholic  $K_2S$  on perchlorinated ether (Malaguti, *A. Ch.* [3] 16, 19).

**DI-CHLORO-TETRA-BROMO-FLUORESCIN**  $C_{20}H_2O_4Cl_2Br_4$  *i.e.*  $C_6H_4Cl_2(C_6O_2)(C_6H_2Br_2OH)_2O$ . *Di-chloro-eosin*. Formed by brominating di-chloro-fluorescein (from resorcin and di-chlorophthalic anhydride). The alkaline solution has a bluer shade than that of eosin (Le Royer, *A.* 238, 358).

Salt.  $C_2H_3K_2O_4Cl_2Br_4$ .

**CHLORO-BROMOFORM** *v.* **CHLORO-DI-BROMO-METHANE**.

**CHLORO-DI-BROMO-HEXANE**  $C_6H_{11}Cl_2Br_2$  (218°). From hexenyl chloride and  $Br$  in  $CCl_4$  (Destrem, *A. Ch.* [5] 27, 58).

**Chloro-tetra-bromo-hexane**  $C_6H_8Cl_4Br_4$ . From  $Br$  and chloro-diallyl (Henry, *C. R.* 87, 171).

**CHLORO-DI-BROMO-HEXYL ALCOHOL**  $C_6H_{11}Cl_2Br_2O$  (c. 254°). S.G. 1.99. From chloro-hexenyl alcohol (186°) and  $Br$  (Destrem, *A. Ch.* [5] 27, 58).

**CHLORO-BROMOHYDRIN** *v.* **CHLORO-BROMO-PROPYL ALCOHOL**.

**CHLORO-BROMO-HYDROQUINONE**  $C_6H_3ClBr(OH)_2$  (172°). Formed by saponification of its di-acetyl-derivative produced by the action of acetyl bromide on chloro-quinone (Schulz, *B.* 15, 666). Formed also by the action of conc.  $HBrAq$  on chloro-quinone (Levy a. Schultz, *A.* 210, 180). Long needles. Sol. alcohol and ether, *sl.* sol. water. On oxidation it gives chloro-bromo-quinone (172°).

**Di-acetyl-derivative**  $C_6H_3ClBr(OAc)_2$  (146°). Short needles. Sol. alcohol and benzene.

**Di-chloro-di-bromo-hydroquinone**  $C_6H_2Cl_2Br_2(OH)_2$  (6:2:5:4:1). (233°). Formed by reduction of the corresponding quinone by  $SnCl_2$  (Levy, *B.* 16, 1447; 18, 2369; Krause, *B.* 12, 54; Hantsch, *B.* 20, 2279). Monoclinic crystals:  $a:b:c = 2.978:1.275$ ;  $\beta = 77^\circ 22'$ .

**Di-acetyl-derivative**  $C_6H_2Cl_2Br_2(OAc)_2$  (370°) (Levy, *B.* 18, 2369).

**Tri-chloro-bromo-hydroquinone**  $C_6H_3Cl_3Br(OH)_2$  (229°). From tri-chloro-bromo-quinone,  $HI$ , and phosphorus (Stenhouse, *A. Suppl.* 6, 219). Also from tri-chloro-quinone and conc.  $HBrAq$  (Levy a. Schultz, *A.* 210, 161). Monoclinic needles,  $a:b:c = 2.915:1.2671$ ;  $\beta = 77^\circ 40'$ . Insol. water, sol. dilute alcohol.

**CHLORO-BROMO-HYDROTHYMOQUINONE**  $C_9H_6Me(C_2H_5)ClBr(OH)_2$  (8:6:2:5:4:1). (53°) or (73°) (?). From chloro-thymoquinone  $C_9H_6Me(C_2H_5)Cl(OH)_2$  (8:6:2:4:1) and  $HBr$ ; or from bromo-thymoquinone  $C_9H_6Me(C_2H_5)Br(OH)_2$  (8:6:2:5:1) (45°) and  $HCl$ . Obtained also by reducing chloro-bromo-thymoquinone (87°) with hydroxylamine (Schniter, *B.* 20, 2318). Needles.

**Chloro-bromo-hydrothymoquinone**  $C_9H_6Me(C_2H_5)ClBr(OH)_2$  (8:6:5:2:4:1). (56°). Formed by reducing chloro-bromo-thymoquinone (78°) with hydroxylamine (S.).

**CHLORO-BROMO-HYDROTOLUQUINONE**  $C_9H_6MeClBr(OH)_2$  (123°) (anhy.). Formed by the action of  $HBr$  upon chloro-toluquinone. Crystals (containing aq). V. sol. alcohol and ether, m. sol. water and ligroin, sl. sol. benzene and chloroform (Schniter, *B.* 20, 2286).

**Chloro-bromo-hydrotoluquinone**  $C_9H_6MeClBr(OH)_2$  (121°) (anhy.). Formed by the action of  $HCl$  upon bromo-toluquinone. Long needles, containing aq (from hot water). Begins to sublime at 105° (Schniter, *B.* 20, 2287).

**CHLORO-BROMO-iodo-ACRYLIC ACID**  $C_3ClBrI.CO_2H$  (116°). Formed by heating bromo-propionic acid with an ethereal solution of  $ICl$  (Mabery a. Lloyd, *Am.* 4, 96; *P. Am.* 4, 17, 99). Monoclinic prisms (from water) melting at 110°; but at 116° when crystallised from  $CS_2$ ; may be sublimed.— $AgA'$ .— $CaA'$ , aq; branching needles.— $BaA'$ , 8:3:4:1; prisms;  $\beta$  25:4 at 20°.

**Chloro-bromo-iodo-acrylic acid**  $C_3HClBrIO_2$  (129°). Glistening colourless plates. V. sol. water, alcohol, and ether. Formed by the action of a chloroform solution of  $ClBr$  upon iodo-propionic acid (Stolz, *B.* 19, 539).

**CHLORO-BROMO-iodo-ETHANE**  $C_2H_3ClBrI$  (194°). S.G. 2.53. Slowly formed by union of  $ICl$  with bromo-ethylene in the cold (Maxwell Simpson, *A.* 136, 142; Henry, *C. R.* 98, 680). Oil. Converted by alcoholic KOH into  $KCl$  (3 pts.),  $KI$  (1 pt.), bromo-iodo-ethylene  $CH_2=CHBrI$ , and chloro-bromo-ethylene  $CH_2=CHClBr$ . Hence the chloro-bromo-iodo-ethane must be a mixture of isomerides.

**CHLORO-BROMO-iodo-PROPANE**  $C_3H_7ClBrI$ . S.G. 2.325. From chloro-iodo-propyl alcohol and  $PBr_3$  (Henry, *B.* 4, 702; cf. 3, 551). Oil.

**DI-CHLORO-BROMO-MESITYLENE**  $C_6H_3BrCl_2$  *i.e.*  $C_6H_3Br(CH_3)(CH_2Cl)_2$  (76°). From bromo-dim-oxy-mesitylene by heating with conc.  $HClAq$  (Colson, *A. Ch.* [6] 6, 101). Readily gives off  $HCl$  in the air.

**CHLORO-BROMO-METHANE**  $CH_2ClBr$  (68°). S.G. 1.991. V.D. 4.43. Formed by the action of excess of bromine on  $CH_3Cl$  (Henry, *C. R.* 101, 599). Oil; not decomposed by light.

**Chloro-di-bromo-methane**  $CHClBr_2$ . *Chloro-bromoform*. (119°) at 730 mm. (*L. a. J.*); (188°)

(J. a. N.). S.G. 1.2445. V.D. 7.37 (for 7.22). Occurs in crude bromine (Dyson, *C. J.* 43, 38). Formed by boiling di-chloro-tetra-bromo-acetone  $\text{CClBr}_2\text{COOCClBr}_2$  with baryta-water. Prepared also by the action of NaOH on chloro-di-bromo-acetic aldehyde (Jacobsen a. Neumaister, *B.* 15, 601). Colourless liquid, of sweetish odour (Levy a. Jedlička, *B.* 20, 2319).

**E. chloro-bromo-methane**  $\text{CHClBr}$ . (92°). S.G. 1.19254. *Bromochloroform*. Colourless liquid. Prepared by the action of NaOH on di-chloro-bromo-acetic aldehyde (Jacobsen a. Neumaister, *B.* 15, 601).

**Tri-chloro-bromo-methane**  $\text{CBrCl}_3$ . (104°). S.G. 1.20550 (Therpe, *C. J.* 37, 203). C.E. (0°-10°) .001089; (0°-100°) .0012065. S.V. 108.43.

**Formation**.—1. By heating  $\text{CCl}_3\text{SO}_2\text{Br}$  with alcohol at 100° (Loew, *Z.* 1869, 624).—2. By bromination of chloroform (Paterno, *G.* 1, 593; Friedel a. Silva, *Bl.* [2] 17, 538).—3. By action of bromine on potassium tri-chloroacetate at 120° (van 't Hoff, *B.* 10, 678).

**Properties**.—Liquid, smelling like carbon tetrachloride.

**CHLORO-BROMO-METHANE SULPHONIC ACID**. Barium salt  $(\text{CHClBrSO}_3)_2\text{Ba}$ . From chloro-sulpho-acetate of barium and bromine (Andreassch, *M.* 7, 170). Satiny plates.

**CHLORO-BROMO-METHYL-ETHYL-GLY. OXALINE**  $\text{C}_2\text{H}_5\text{ClBrN}$ , i.e.  $\text{C}_2\text{H}_5\text{Br}(\text{CH}_2)(\text{C}_2\text{H}_5)\text{N}$ . *Chloro-bromo-oxal ethylene*. From chloro-methyl-ethyl glyoxaline by treatment with Br in  $\text{CS}_2$  followed by boiling water (Wallach, *A.* 214, 290; *B.* 10, 1193). Oil with narcotic odour. Solidifies with difficulty. Sl. sol. water. Not volatile. With Br it forms  $\text{C}_2\text{H}_5\text{ClBrNBr}$ . **Salts**.— $\text{B}^+\text{HCl}$ : prisms.— $(\text{B}^+\text{HCl})_2\text{PtCl}_4$ .— $\text{B}^+\text{AgNO}_3$ .

**CHLORO-BROMO-NAPHTHALENE**  $\text{C}_{10}\text{H}_7\text{ClBr}$  [14]. [115°]. From ( $\alpha$ )-naphthylamine *p*-sulphonic acid by conversion into bromo-naphthalene sulphonic acid, and treatment of the latter with  $\text{PCl}_5$  (Clève, *Bl.* [2] 26, 540).

**Chloro-bromo-naphthalene**  $\text{C}_{10}\text{H}_7\text{ClBr}$  [119°]. Formed, together with the following, by the action of Br (1 mol.) on ( $\alpha$ )-chloro-naphthalene (1 mol.), or of Cl on ( $\alpha$ )-bromo-naphthalene (Guarreschi a. Bignelli, *G.* 16, 152; *C. C.* 1837, 518). Thin plates. Oxidised by  $\text{CrO}_3$  to chloro-phthalic acid [184°]. Possibly identical with the preceding.

**Chloro-bromo-naphthalene**  $\text{C}_{10}\text{H}_7\text{ClBr}$  [87°]. (303° uncor.). Prepared as above. Needles (by sublimation).  $\text{CrO}_3$  in acetic acid gives chloro-bromo-naphthoquinone [167°] and chloro-bromophthalide.

**Di-chloro-bromo-naphthalene**  $\text{C}_{10}\text{H}_6\text{Cl}_2\text{Br}$  [80°]. From di-chloro-naphthalene [88°] and Br in the cold (Laurent). Slender needles.

The following chloro-bromo-naphthalenes described by Laurent (*A. Ch.* 49, 218; 52, 275) are insufficiently characterised:  $\text{C}_{10}\text{H}_6\text{Cl}_2\text{Br}_2$  (two),  $\text{C}_{10}\text{H}_5\text{Cl}_3\text{Br}$  (three), and  $\text{C}_{10}\text{H}_4\text{Cl}_4\text{Br}_2$  (two).

The following compounds are probably mixtures or molecular compounds: ( $\alpha$ )  $\text{C}_{10}\text{H}_6\text{Cl}_2\text{Br}$ , [76°]. From di-chloro-naphthalene [88°] and Br followed by alcoholic KOH (Faust a. Saame, *A.* 160, 69). Needles (from ether-alcohol). ( $\beta$ )  $\text{C}_{10}\text{H}_6\text{Cl}_2\text{Br}$ , [78°]. From di-chloro-naph-

thalene [88°] by successive treatment with Br and alcoholic KOH (F. a. S.).

**CHLORO-BROMO-NAPHTHALENE TETRA-BROMIDE**  $\text{C}_{10}\text{H}_2\text{Cl}_4\text{Br}_4$ , [110°]. From chloro-naphthalene and Br (Laprent). (Triclinic columns.

**CHLORO- DI - BROMO - NAPHTHALENE TETRA-CHLORIDE**  $\text{C}_{10}\text{H}_2\text{Cl}_6\text{Br}_2$ , [150°]. From di-bromo-naphthalene tetra-chloride and chlorine. Triclinic columns, sl. sol. ether.

**CHLORO-BROMO-NAPHTHOQUINONE**  $\text{C}_{10}\text{H}_6\text{ClBrO}_2$ , [167°]. From chloro-bromo-naphthalene [87°] by  $\text{CrO}_3$  in HOAc (Guarreschi, *C. C.* 1887, 518).

**CHLORO-BROMO-NITRO-ANILINE**  $\text{C}_6\text{H}_4\text{ClBrN}_2$ , i.e.  $\text{C}_6\text{H}_4\text{ClBr}(\text{NO}_2)(\text{NH}_2)$  [4:6:2:1]. [106°]. From chloro-nitro-aniline in HOAc by bromine-vapour (Körner, *J.* 1875, 352; *G.* 4, 305). Orange-yellow needles.

**CHLORO-BROMO-NITRO-BENZENE**  $\text{C}_6\text{H}_4\text{ClBr}(\text{NO}_2)$  [1:3:5]. [82.5°]. From the preceding by diazo-reaction (Körner, *G.* 4, 377). Lamine.

**Chloro-bromo-nitro-benzene**  $\text{C}_6\text{H}_4\text{ClBr}(\text{NO}_2)$  [1:4:2]. [69°]. From *p*-chloro-bromo-benzene and  $\text{HNO}_3$  (K.).

**Chloro-bromo-nitro-benzene**  $\text{C}_6\text{H}_4\text{ClBr}(\text{NO}_2)$  [1:3:4]. [49.5°]. From chloro-nitro-aniline [123°] by displacing  $\text{NH}_2$  by Br (K.). With alcoholic  $\text{NH}_3$  at 160° it regenerates the chloro-nitro-aniline.

**TRI-CHLORO-DI-BROMO-NITRO-ETHANE**  $\text{CCl}_2\text{Br}_2\text{CClBr}(\text{NO}_2)$ . From  $\text{CCl}_2\text{CCl}(\text{NO}_2)$  and Br at 150°. Crystalline (Hoch, *J. pr.* [2] 6, 95).

**CHLORO-BROMO-DI-NITRO-METHANE**  $\text{CClBr}(\text{NO}_2)_2$ . Formed by passing chlorine into an aqueous solution of potassium-bromo-dinitro-methane  $\text{CKBr}(\text{NO}_2)_2$  (Losanitsch, *B.* 17, 848). Oil. V. sol. alcohol, insol. water. By caustic alkalis the Br atom is displaced by a metallic atom.

**Chloro-di-bromo-nitro-methane**  $\text{CClBr}_2(\text{NO}_2)$ . S.G. 1.2421. Formed by simultaneous action of bromine and potash on  $\text{CClH}_2(\text{NO}_2)$  (Tscherniak, *B.* 8, 610). An oil, insol. potash, volatile with steam.

**CHLORO-BROMO-NITRO-PHENOL**  $\text{C}_6\text{H}_4\text{ClBr}(\text{NO}_2)\text{OH}$  [4:2:6:1]. [125°]. From (4,6,1)-chloro-nitro-phenol [87°] and Br in HOAc in the cold (Ling, *C. J.* 51, 787). Converted by Br and water at 100° into tetra-bromo-quinone.  $\text{C}_6\text{H}_2\text{Cl}_4\text{Br}_2\text{NO}_2\text{K}$ : dark red needles.— $\text{BaA}$ , aq.— $\text{CaA}$ , 2½ aq.

**Chloro-bromo-nitro-phenol**  $\text{C}_6\text{H}_4\text{ClBr}(\text{NO}_2)\text{OH}$  [2:4:6:1]. [120°]. Formed by boiling (4,6,1)-chloro-nitro-phenol [87°] with Br and HOAc, an isomerite changed taking place (L.). Formed also by chlorinating (4,6,1)-bromo-nitro-phenol [88°]. When heated with Br and water it gives chlorotri-bromo-quinone.— $\text{C}_6\text{H}_2\text{Cl}_3\text{Br}_3\text{NO}_2\text{K}$ : red plates.— $\text{CaA}$ , 7 aq.

**TRI-CHLORO-*iso*-DI-BROMO-*iso*-DI-NITRO-DI-PHENYL-ETHANE**

$\text{CCl}_2\text{CH}(\text{C}_6\text{H}_4\text{Br})_2$ , [170°]. From  $\text{CCl}_2\text{CH}(\text{C}_6\text{H}_5)_2$  and fuming  $\text{HNO}_3$  (Zeidler, *B.* 7, 1180). Needles (from alcohol).

**CHLORO-BROMO-DI-OXY-NAPHTHO-QUINONE DIBROMIDE**  $\text{C}_{10}\text{H}_2\text{ClBrO}_4$ , 4a.

$\text{C}_6\text{H}_5\text{COO}(\text{OH})\text{COOCClBr}$ , [105°]. From bromo-ox-

a)-naphthoquinone and Cl in HOAc. Needles. Oxidation gives a body [141°] (Zincke a. Gerland, B. 20, 3216).

**DI-CHLORO-DI-BROMO-TETRA-OXY-DIPHENYL**  $\text{C}_6\text{H}_4\text{ClBr}(\text{OH})_2\text{C}_6\text{H}_4\text{ClBr}(\text{OH})_2$ . [266°]. From di-chloro-tri-bromo-resorcin by successive treatment with  $\text{NaHSO}_3$  and with  $\text{HCl}$  (Benedikt, M. 4, 227°).

**CHLORO-BROMO-DI-OXY-QUINONE**  $\text{C}_6\text{H}_2\text{ClBr}(\text{OH})_2\text{O}_2$  [6:3:5:2:4:1] (Hantzsch a. Schnier, B. 20, 2279). From *m*-di-chloro-*m*-di-bromo-quinone and aqueous KOH (Krause, B. 2, 54) or tri-chloro-bromo-quinone (Levy, A. 210, 163; B. 16, 1444; B. 18, 2370). Red leaflets (containing aq.); may be sublimed— $\text{K}_2\text{A}''$  2aq.— $\text{Na}_2\text{A}''$  2aq.—Ag.<sup>+</sup>

**CHLORO-DI-BROMO-OXY-VALERIC ACID**  $\text{C}_5\text{H}_4\text{ClBr}_2\text{O}_4$ . [169°]. Prepared by the addition of Br to chloro-oxy-valeric acid (Pinner a. Klein, B. 11, 1497). Sol. ether, insol. benzene.

• **CHLORO-DI-BROMO-PENTANE**  $\text{C}_5\text{H}_8\text{ClBr}_2$ . From isoprene hydrochloride  $\text{C}_5\text{H}_8\text{HCl}$  and Br (Bouchardat, C. R. 89, 1217).

**Di-chloro-di-bromo-pentane**  $\text{CH}_3\text{CHBr.CBrCl.CHCl.CH}_3$ . (c. 143°) at 31 mm. From di-chloro-amylenes  $\text{CH}_3\text{CH:CH.CCl.CHCl.CH}_3$  and bromine (Thurnlaek, A. 223, 161).

**Di-chloro-di-bromo-pentane**  $\text{C}_5\text{H}_8\text{Cl}_2\text{Br}_2$ . (230°-240°). From di-chloro-amylenes (146°) and Br (Pinner, A. 179, 86).

**DI-CHLORO-BROMO-PHENOL**  $\text{C}_6\text{H}_3\text{Cl}_2\text{Br}(\text{OH})$ . [268°] (Garzino, C. C. 1887, 1546). From (4,2,1)-di-chloro-phenol and Br. *Tri-chloro-bromo-phenol*  $\text{C}_6\text{H}_2\text{Cl}_3\text{Br}(\text{OH})$ . Bromine converts tri-chloro-phenol [67°] into  $\text{C}_6\text{H}_2\text{Cl}_3\text{BrO}$  [99°]. This is perhaps  $\text{C}_6\text{H}_2\text{Cl}_3(\text{OBr})$ ; it is converted, by heating under water, into an isomeric, which is probably  $\text{C}_6\text{H}_2\text{Cl}_3\text{Br}(\text{OH})$  (Benedikt, M. 4, 236).

**TRI-CHLORO-DI-BROMO-DI-PHENYLETHANE**  $\text{CCl}_2\text{CH}(\text{C}_6\text{H}_2\text{Br}_2)_2$ . [141°]. From bromo-benzene (1 pt.), chloral (2 pts.), and  $\text{H}_2\text{SO}_4$  (Zeidler, B. 7, 1180). Silky needles.

**Di-chloro-di-bromo-di-phenyl-ethylene**  $\text{CCl}_2\text{C}(\text{C}_6\text{H}_2\text{Br}_2)_2$ . [120°]. Formed by the action of alcoholic KOH upon the preceding body (Zeidler, B. 7, 1180). Needles (from alcohol).

**$\beta$ -CHLORO- $\alpha$ -BROMO- $\beta$ -PHENYL-PROPIONIC ACID**  $\text{C}_9\text{H}_7\text{CHCl.CHBr.CO}_2\text{H}$ . [182°]. From  $\alpha$ -bromo- $\beta$ -oxy- $\beta$ -phenyl-propionic acid and conc.  $\text{HCl}$  at 100° (Glaser, A. 147, 92). Monoclinic tables (from chloroform). Boiling water forms HCl and bromo-oxy-phenyl-propionic acid, together with a little phenyl-acetic aldehyde and  $\alpha$ -bromo-styrene.

**$\alpha$ -Chloro- $\beta$ -bromo- $\beta$ -phenyl-propionic acid**  $\text{C}_9\text{H}_7\text{CHBr.CHCl.CO}_2\text{H}$ . [185°]. From  $\alpha$ -chloro- $\beta$ -oxy- $\beta$ -phenyl-propionic acid and conc.  $\text{HBr}$  at 60° (G.). Monoclinic tables (from chloroform). Boiling water gives  $\alpha$ -chloro-styrene and a little chloro-oxy-phenyl-propionic acid, and phenyl-acetic aldehyde.

**$\alpha$ -Chloro- $\alpha\beta$ -di-bromo- $\beta$ -phenyl-propionic acid**  $\text{C}_9\text{H}_7\text{CHBr.CBrCl.CO}_2\text{H}$ . [186°]. From  $\alpha$ -chloro- $\beta$ -phenyl-propionic acid and Br (Forrer, B. 16, 855). Tables (from water).

**CHLORO-BROMO-PHTHALIDE**

$\text{C}_8\text{H}_4\text{ClBr} \begin{smallmatrix} \text{CH} \\ \diagup \text{GO} \diagdown \end{smallmatrix} \text{O}$ . [179°]. Formed by oxidation of chloro-bromo-naphthalene [67°] with  $\text{CrO}_2$  (Guaracchi, B. 19, 1164).

Vol. II.

**CHLORO-BROMO-PICRIN** v. CHLORO-DI-BROMO-NITRO-METHANE.

**$\omega$ -CHLORO- $\alpha$ -BROMO-PROPANE**  $\text{C}_3\text{H}_5\text{ClBr}$  i.e.  $\text{CH}_3\text{CHBr.CH}_2\text{Cl}$ . *Propylene chloro-bromide*. (120°). Formed in small quantity, together with  $\text{CH}_3\text{Br.CH}_2\text{CH}_2\text{Cl}$  by treating allyl chloride with fuming HBr (Reboul, A. Ch. [5] 14, 497). Converted by alcoholic KOH into HCl and bromo-propylene.

**$\alpha$ -Chloro- $\omega$ -bromo-propane**  $\text{CH}_3\text{CHCl.CH}_2\text{Br}$ . (120°). S.G. 2 1.585. V.D. 5.52 (calc. 5.45). From propylene bromide by boiling with  $\text{HgCl}_2$  (Friedel a. Silva, Bl. [3] 17, 532). Alcoholic KOH converts it into chloro-propylene (25°-30°).

**Chloro-bromo-propane**  $\text{C}_3\text{H}_5\text{ClBr}$ . (119°). From ClBr and  $\text{C}_3\text{H}_4$  (Maxwell Simpson, Pr. 27, 119). Probably a mixture of the two preceding bodies.

**$\omega$ -Chloro- $\beta$ -bromo-propane**  $\text{CH}_3\text{Br.CH}_2\text{CH}_2\text{Cl}$ . *Tri-methylene chloro-bromide*. (142°). S.G. 2 1.463. From tri-methylene bromide and  $\text{HgCl}_2$ . It is also the chief product of the union of HBr with allyl chloride (Reboul). Boiling alcoholic KOH gives ethyl-allyl oxide.

**$\alpha$ -Chloro- $\alpha$ -bromo-propane**  $\text{CH}_3\text{CClBr.CH}_3$ . *Acetone chloro-bromide*. (c. 95°). S.G. 2 1.474. From  $\alpha$ -chloro-propylene  $\text{CH}_3\text{CCl.CH}_2$  and cold conc.  $\text{HBr}$  (Reboul, A. Ch. [5] 14, 482). Alcoholic KOH gives  $\alpha$ -chloro-propylene and allylene.

**$\omega$ -Chloro- $\omega$ -bromo-propane**  $\text{CH}_3\text{CH}_2\text{CHClBr}$ . (111°). S.G. 2 1.59. From  $\omega$ -chloro-propylene  $\text{CH}_3\text{CH}_2\text{CHCl}$  and HBr (R.). Alcoholic KOH gives  $\text{CH}_3\text{CH}_2\text{CHCl}$ .

**Chloro-di-bromo-propane**  $\text{C}_3\text{H}_5\text{ClBr}_2$ . (198°). From allyl bromide and ClBr. They unite slowly in the cold (Maxwell Simpson, Pr. 27, 119).

**$\omega$ -Chloro- $\omega\alpha$ -di-bromo-propane**  $\text{CH}_3\text{CHBr.CHClBr}$  (177° cor.). From  $\text{CH}_3\text{CH}_2\text{CHCl}$  and Br (Reboul, Bl. [2] 26, 278).

**$\alpha$ -Chloro- $\alpha\alpha$ -di-bromo-propane**  $\text{CH}_3\text{CClBr.CH}_2\text{Br}$ . (170°). S.G. 2 2.064 (Friedel, A. 112, 237). From  $\text{CH}_3\text{CCl.CH}_2$  and Br (F. a. S.; R.). With alcoholic KOH it gives  $\text{C}_2\text{H}_5\text{ClBr}$  and ethyl-propargyloxy  $\text{CH}_3\text{C}\equiv\text{CH.OEt}$  (Oppenheim, A. Suppl. 6, 372).

**$\omega$ -Chloro- $\alpha\beta$ -di-bromo-propane**  $\text{CH}_3\text{Br.CHBr.CH}_2\text{Cl}$ . (195°) (O.); (203°) (R.). S.G. 2 2.085 (R.). From allyl chloride and Br

(O.). Also from epichlorhydrin  $\text{CH}_2\text{CHCH}_2\text{Cl}$  and  $\text{PBr}_3$  or  $\text{PCl}_3$  (Reboul, A. Suppl. 1, 230; Darmstädter, A. 152, 320). Solid KOH gives  $\text{CH}_3\text{CBr.CHCl}$ . Alcoholic KOH gives rise to  $\text{CH}_3\text{C}\equiv\text{CH.OEt}$ .

**$\alpha$ -Chloro- $\omega\beta$ -di-bromo-propane**  $\text{CH}_3\text{Br.CHCl.CH}_2\text{Br}$ . (200°). From glycerin dibromhydrin and  $\text{PCl}_5$  (Berthelot a. de Luca, J. pr. 72, 317).

**Chloro-tri-bromo-propane**  $\text{C}_3\text{H}_3\text{ClBr}_3$ . (288°). S.G. 2 2.39. From chloro-bromo-propylene (from glycide) and Br (Reboul, A. Suppl. 1, 231).

**Di-chloro-bromo-propane**  $\text{C}_3\text{H}_4\text{Cl}_2\text{Br}$ . (180°-187°). From allyl bromide and ClBr at 100° (M. Simpson, Pr. 27, 119).

**$\alpha\beta$ -Di-chloro- $\alpha$ -bromo-propane**  $\text{CH}_3\text{Cl.CHBr.CH}_2\text{Cl}$ . (176°). From *s*-dichlorhydrin and  $\text{PBr}_3$  (Berthelot a. de Luca, J. pr. 17, 317).

***αα*-Di-chloro-β-bromo-propane**

$\text{CH}_2\text{Cl.CHCl.CH}_2\text{Br}$ . From  $\text{CH}_2\text{Cl.CH(OH).CH}_2\text{Br}$  and PBr<sub>3</sub>.

Di-chloro-bromo-propane  $\text{C}_3\text{H}_4\text{Cl}_2\text{Br}$ . (156°–160°). From bromo-propylene and chlorine (Linnemann, A. 138, 123).

***αα*-Di-chloro-*αβ*-di-bromo-propane**

$\text{CH}_2\text{Cl.CClBr.CH}_2\text{Br}$ . (205°). S.G. 2.2161. From  $\text{CH}_2\text{Cl.CCl.CH}_2\text{Br}$  and Br (Friedel & Silva, C. R. 74, 805; 75, 31; B. [2] 17, 886).

***αβ*-Di-chloro-*αβ*-di-bromo-propane**

$\text{CH}_2\text{Cl.CHBr.CHClBr}$ . (221°) (F. a. S.); (212°) (Hartenstein, J. pr. [2] 7, 313). S.G. 2.219 (F. a. S.); 175.2–688 (H.). From  $\text{CH}_2\text{Cl.CH.CHCl}$  and Br (B.; F. a. S.; E.).

***αα*-Di-chloro-*αα*-di-bromo-propane**

$\text{CH}_2\text{Cl.CClBr.CHClBr}$ . (189°). From allylene dichloride and Br (F. a. S.; Pinner, A. 179, 44). Alcoholic KOH gives  $\text{C}_2\text{H}_3\text{Cl}_2\text{Br}$  (143°).

Di-chloro-tri-bromo-propane  $\text{C}_3\text{H}_2\text{Cl}_4\text{Br}_2$ . [207°]. From di-chloro-bromo-propylene (143°) and Br (P.). Alcoholic KOH reconverts it into  $\text{C}_2\text{H}_3\text{Cl}_2\text{Br}$ .

***β*-CHLORO-*α*-BROMO-PROPIONIC ACID**

$\text{CH}_2\text{Cl.CHBr.CO}_2\text{H}$ . [37°]. (c. 213°). Formed by the action of  $\text{HNO}_3$  on the product of the union of BrOH with allyl chloride (Henry, B. 7, 757).

***α*-Chloro-β-bromo-propionic acid**

$\text{CH}_2\text{Br.CHCl.CO}_2\text{H}$ . [37°]. (c. 213°). Formed similarly by oxidising the product of the union of ClOH with allyl bromide (H.).

**Chloro-tri-bromo-propionic acid**

$\text{C}_2\text{HClBr}_2\text{CO}_2\text{H}$ . [103°]. From chloro-bromo-acrylic acid [70°] and Br (1 mol.) by heating for 2 hours at 100°; the yield is 70 p.c. (Mabery a. Weber, Am. 4, 104; 6, 255; P. Am. A. 17, 106). Triclinic prisms (from  $\text{CS}_2$ ); v. sol. alcohol and ether. Boiling baryta-water forms  $\text{C}_2\text{HClBr}_2$ ; cold baryta-water gives chloro-di-bromo-acrylic acid.— $\text{KA}'$  aq.— $\text{CA}'$  aq.— $\text{BA}'$  aq.: S. 23 at 20°.

**Di-chloro-di-bromo-propionic acid**

$\text{C}_2\text{HClBr.CO}_2\text{H}$ . [95°]. Prepared by the combination of di-chloro-acrylic acid [86°] by heating with bromine at 100° for several hours (Hill a. Mabery, P. Am. A. 17, 140; Am. 4, 267; B. 14, 1679). Triclinic prisms,  $a:b:c = 1.023:1.1:0.52$ ;  $\alpha = 91^\circ$ ;  $\beta = 76^\circ 31'$ ;  $\gamma = 108^\circ 52'$ . V. sol. water, alcohol, and ether, m. sol.  $\text{CS}_2$  or benzene.

**Salts.**— $\text{A}'\text{Ag}$  flat needles.— $\text{A}'\text{Ba}$ : long easily soluble needles.

***αβ*-Di-chloro-*ββ*-di-bromo-propionic acid**

$\text{CClBr}_2\text{CHCl.CO}_2\text{H}$ . [100°]. Prepared by passing chlorine into di-bromo-acrylic acid at 100°; the yield is 96 p.c. (Mabery a. Nicholson, Am. 6, 166; cf. Am. 4, 270; P. Am. A. 17, 140; B. 14, 1680). Monoclinic prisms; v. s. sol. ether and alcohol, sol. hot  $\text{CHCl}_3$  and  $\text{CS}_2$ , sl. sol. water.

**Salts.**— $\text{CA}'$  aq.— $\text{KA}'$  2aq.

**Tri-chloro-bromo-propionic acid**

$\text{C}_2\text{HClBr.CO}_2\text{H}$ . [84°]. Prepared by passing chlorine into a cold chloroform solution of chloro-bromo-acrylic acid in sunlight. The yield is 90 p.c. (Mabery, Am. 9, 1). Trimetric prisms; sl. sol. water, sol. ether, alcohol, and  $\text{CHCl}_3$ . Its salts are unstable.— $\text{KA}'$  2aq: trimetric plates.— $\text{CA}'$  aq.: oblique prisms.— $\text{BA}'$  aq.: gummy.

**Tetra-chloro-bromo-propionic acid**

$\text{CClBr}_2\text{CCl.CO}_2\text{H}$ . [225°]. Prepared by passing chlorine into a solution of bromo-propionic acid

in chloroform, till the product crystallises out (Mabery, Am. 6, 155). Sl. sol.  $\text{CS}_2$  and chloroform. Its salts are unstable.

***α*-CHLORO-*β*-BROMO-PROPYL ALCOHOL**

$\text{C}_2\text{H}_3\text{ClBrO}$  i.e.  $\text{CH}_2\text{Br.CHCl.CH}_2\text{OH}$  (197°). S.G. 2.1764. From allyl bromide and HOCl (Henry, B. 7, 409, 765). Oxidation gives chloro-bromo-propionic acid (v. *supra*).

***β*-Chloro-*α*-bromo-propyl alcohol**

$\text{CH}_2\text{Cl.CHBr.CH}_2\text{OH}$ . (197°). S.G. 2.1762. From allyl chloride and HOBr (H.). Oxidised by  $\text{HNO}_3$  to chloro-bromo-propionic acid [37°], (215°).

Nitrate  $\text{CH}_2(\text{NO}_2)\text{CHBr.CH}_2\text{OH}$ . From the alcohol,  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ . Oil.

***α*-chloro-*α*-bromo-isopropyl alcohol**

$\text{CH}_2\text{Br.CH(OH).CH}_2\text{Cl}$ . *Chloro-bromhydrin*. (197°). S.G. 2.1740. From epichlorhydrin and HBr, or from epibromhydrin and HCl (Reboul, A. Suppl. 1, 225). Conc. KOH splits it up into HBr and epichlorhydrin. Oxidation gives chloro-bromo-acetone [35°] (Theegarten, B. 6, 1212). Also from epichlorhydrin and Br at 100° (Grimaux a. Adam, B. [2] 33, 257).

*Ethyl ether*  $\text{C}_2\text{H}_3\text{ClBrOEt}$ . (187°). From

epichlorhydrin  $\text{CH}_2\text{CHCl.CH}_2\text{Cl}$  and EtBr at 200° (Reboul a. Lourenço, A. 119, 238).

**CHLORO-BROMO-PROPYL-BENZENE v.****CHLORO-BROMO-CUMENE.**

**CHLORO-BROMO-PROPYLBENZENE**  $\text{C}_9\text{H}_8\text{ClBr}$  i.e.  $\text{CH}_2\text{CCLCH}_2\text{Br}$ . (121°). From *α*-chloro-allyl alcohol and PBr<sub>3</sub> (Henry, C. R. 95, 849).

**Chloro-bromo-propylene**  $\text{CHBr.CH.CHCl}$ . (120°). S.G. 2.163. From *β*-bromo-allyl alcohol and PCl<sub>3</sub> (Henry, B. 5, 453).

**Chloro-bromo-propylene**  $\text{CH}_2\text{CBr.CHCl}$ . (127°) (R.); (120°) (H.). S.G. 2.169 (R.). From  $\text{CH}_2\text{Br.CHBr.CHCl}$  and solid KOH (Reboul, A. Suppl. 1, 230; Oppenheim, A. Suppl. 6, 374). From *β*-bromo-allyl alcohol and PCl<sub>3</sub> (H.).

**Chloro-bromo-propylene**  $\text{CH}_2\text{CCl.CHBr}$  (?) (105°). From  $\text{CH}_2\text{CClBr.CH}_2\text{Br}$  and alcoholic KOH (Friedel, A. 112, 237).

**Di-chloro-bromo-propylene**  $\text{CH}_2\text{CCl.CClBr}$  (?) (143°). From allylene di-chloro-di-bromide and alcoholic KOH (Pinner, A. 179, 45). Br gives  $\text{C}_2\text{H}_3\text{Cl}_2\text{Br}$  [207°].

**CHLORO-BROMO-QUINONE**  $\text{C}_6\text{H}_2\text{ClBrO}_2$  [172°]. Formed by oxidation of chloro-bromo-hydroquinone (Schulz, B. 15, 656).

***m*-Di-chloro-*m*-di-bromo-quinone**  $\text{C}_6\text{Cl}_2\text{Br}_2\text{O}_2$  [6:2:5:3:4:1]. [233°].

**Formation.**—1. Formed by the action of Br on di-chloro-phenylene di-imide (from bleaching-powder and *p*-phenylene-diamine hydrochloride) (Krause, B. 12, 58).—2. By bromination of *m*-di-chloro-quinone  $\text{C}_6\text{H}_2\text{Cl}_2\text{O}_2$  [6:2:4:1] (Levy, B. 16, 1447).—3. By bromination of *p*-di-chloro-quinone  $\text{C}_6\text{H}_2\text{Cl}_2\text{O}_2$  [6:3:4:1] (Levy, B. 18, 2867); in this case one of the Cl atoms must undergo transposition from the *p* to the *m*-position.—4. From hydroquinone, conc. HCl and Br (Benedikt, M. 1, 347).

**Properties.**—Monoclinic golden-brown tables;  $a:b:c = 1.445:1.3:0.286$ ;  $\beta = 74^\circ 31'$  (L.). Sl. sol. ether and alcohol, insol. water.

**Reactions.**—It is very readily reduced by hydroxylamine hydrochloride to the corresponding hydroquinone [224°], whose acetyl derivative

melts at [370°] (Hantzsch a. Schfiter, *B. 20*, 1279). By boiling with aqueous alkalis it is converted into a chloro-bromo-di-oxy-quinone  $C_6ClBr(OH)_2O$ .

**Tri-chloro-bromo-quinone**  $C_6Cl_3BrO_2$ . From tri-chloro-quinone and Br at 180° (Stenhouse, *A. Suppl.* 6, 219). Also from tri-chloro-bromo-hydroquinone and conc.  $HNO_3$  (Levy a. Schultz, *A.* 210, 169). Golden monoclinic pyramids;  $abc:a = 1.48:1.2:0.5$ ;  $\beta = 72^\circ 41'$ . Sublimes at 160°. Dilute KOH gives chloro-bromo-di-oxy-quinone.

#### CHLORO-DI-BROMO-RESORCIN

**CHBr<sub>2</sub>Cl(OH)<sub>2</sub>**. [105°]. Got by adding excess of bromine water to a solution of chloro-resorcin at 80°. Crystallises from water in silky needles (G. Reinhardt, *J. pr.* [2] 17, 325).

**Chloro-di-bromo-resorcin**  $C_6HBr_2Cl(OH)_2$ . [86°]. From  $C_6HBr_2Cl(OCl)(OB)$  and  $NaHSO_4$  (Benedikt, *M.* 4, 227).

**Di-chloro-bromo-resorcin**  $C_6HBrCl_2(OH)_2$ . [100°]. From Br and di-chloro-resorcin. Silky needles (from water) (B.).

**Di-chloro-tri-bromo-resorcin**  $C_6HCl_3Br_2O_2$  i.e.  $C_6HBr_2Cl(OCl)(OB)_2$  (2). Formed by adding Br (216 g.) dissolved in conc.  $HClAq$  (1,000 c.c.) to a solution of resorcin (50 g.) in water (2,000 c.c.) (B.). Yellow crystals. At 175° it gives crystalline  $C_6H_2Cl_3Br_2O$ , which is reduced by tin and HCl to di-chloro-di-bromo-tetra-oxy-diphenyl.

**Tri-chloro-di-bromo-resorcin**  $C_6HCl_4(OBr)_2$ . [100°]. Prepared by adding Br to tri-chloro-resorcin suspended in dilute HCl (B.). Small golden crystals. Gives off Br (1 mol.) on heating. Reduced by tin and HCl to tri-chloro-resorcin.

**HEXA-BROMO-TRI-CHLORO-DI-THIENYL-ETHANE**  $CCl_2CH(CBrS)_2$ . [176°]. Formed by bromination of di-thienyl-tri-chloro-ethane (Peter, *B.* 17, 1343). White crystalline powder. V. sol. ether and chloroform, sl. sol. alcohol. Does not give the indophenine reaction.

#### CHLORO-BROMO-THYMOQUINONE

$C_6MePrClBrO_2$  [1:4:5:2:3:6]. [78°]. Formed by bromination of *m*-chloro-thymoquinone  $C_6HMePrClO_2$  [1:4:5:3:6]. Yellow plates (Schniter, *B.* 20, 1319).

**Chloro-bromo-thymoquinone**  $C_6MePrClBrO_2$  [1:4:2:5:3:6]. *p*-Chloro-benzyl bromide. [87°]. Formation.—1. By oxidation of the corresponding hydroquinone with  $FeCl_3$ .—2. By bromination of *o*-chloro-thymoquinone  $C_6HMePrClO_2$  [1:4:2:3:6]. Golden-yellow plates (Schniter, *B.* 20, 1318).

***p*-CHLORO- $\omega$ -BROMO-TOLUENE**  $C_6H_4ClBr$  i.e.  $C_6H_4Cl.CH_2Br$ . [48.5°] (225°–230°). From *p*-chloro-toluene and Br (Jackson a. Field, *Am.* 1, 102). White needles (from alcohol); aromatic odour; volatile in the air.

**$\omega$ -Chloro-*p*-bromo-toluene**  $C_6H_4Br.CH_2Cl$ . *b*-Bromo-benzyl chloride. Obtained, mixed with an equivalent quantity of  $C_6H_4Br.CH_2Br$ , by brominating benzyl chloride (Erdt, *G.* 17, 193). NaOEt converts it into  $C_6H_4Br.CH_2OEt$  (249°). **Di-chloro-bromo-toluene**  $C_6H_3Cl_2Br$ . (280°–290°) (Jackson a. Field, *B.* 11, 905).

#### CHLORO-BROMO-TOLUOQUINONE

$C_6HMeClBrO_2$ . [111°]. From the hydroquinone [123°], by oxidation. Thick needles. V. sol. ether, benzene, and chloroform; scarcely sol. water (Schniter, *B.* 20, 2287).

**Chloro-bromo-toluquinone**  $C_6HMeClBrO_2$ . [160°]. From the hydroquinone, [121°], by oxidation. Glistening yellow plates (from alcohol) (Schniter, *B.* 20, 2287).

**TRI-CHLORO-DI-BROMO-DI-TOLYL-ETHANE**  $C_{10}H_6Cl_3Br_2$ . [148°]. From tri-chloro-di-tolyl-ethane and Br in  $CS_2$  (O. Fischer, *B.* 7, 1191).

**DI-CHLORO-BROMO-VINYL-BENZOIC ACID**  $C_8H_5Cl_2BrO_2$  i.e.  $CClBr:CClC_6H_4.CO_2H$ . [174°]. From  $C_6H_5 < \begin{smallmatrix} CO \\ CClBr \end{smallmatrix} > CClBr$  and alcoholic NaOH diluted with water (Zincke a. Fröhlich, *B.* 20, 2056). Needles.

*Methyl ether MeA.* s[82°].

#### CHLORO-BUTANE v. BUTYL CHLORIDE.

**$\alpha$ -Di-chloro-butane**  $CH_3.CCl_2.CH_2.CH_3$ . (96°). From methyl ethyl ketone and  $PCl_5$  (Braylants, *B.* 8, 412). Dry KOH gives  $CH_3.CCl_2.CH_2.CH_3$ . Alcoholic KOH gives  $CH_3.C:CCl_2$  (Favorsky, *Bl.* [2] 45, 247).

**$\omega$ -Di-chloro-isobutane**  $(CH_3)_2CH.CHCl_2$ . *Isobutylidene chloride*. (104°). S.G. 12 1.011. V.D. 127 (H = 1). From isobutyric aldehyde and  $PCl_5$  (Oeconomides, *C. R.* 92, 884). Aqueous  $NH_3$  at 180° gives chloro-isobutylene (67°).

**Di-chloro-isobutane**  $C_4H_8Cl_2$ . (107°). From chloro-isobutylene  $CH_3.CMe.CH_2Cl$  and conc. HCl (Chécheoukoff, *Bl.* [2] 43, 112).

**Di-chloro-butane**  $C_4H_{10}Cl_2$ . (128°) (P.); (125°) (Faraday). S.G. 12 1.112. V.D. 4.43. Formed by union of Cl with the mixture of butylenes (*q. v.*) obtained by treating isobutyl alcohol (25 pts.) with  $H_2SO_4$  (25 pts.),  $CaSO_4$  (40 pts.), and  $K_2SO_4$  (10 pts.) (Puchot, *A. Ch.* [5] 28, 508; cf. Faraday, *Tr.* 1825, 440; Kolbe, *A.* 69, 269; 64, 339).

**Di-chloro-butane**  $C_4H_{10}Cl_2$ . (106°). From *tert*-butyl chloride and Cl in daylight (D'Ottreppe de Bouvette, *Belg. Acad. Bull.* [3] 4, 359).

**Tetra-chloro-butane**  $C_4H_6Cl_4$  i.e.  $CH_2.CCl_2.CHCl_2.CHCl_2$ . (85°) at 10 mm. From tri-chloro-butyl alcohol by gradual addition of  $PCl_5$  (Garzarolli-Thurnlackh, *A.* 213, 372). Oil. **Tetra-chloro-butane**  $CH_2Cl.CHCl_2.CHCl_2.CH_2Cl$ . *Butinene tetra-chloride*. [78°]. From butinene and Cl. Also from erythrite and  $PCl_5$  (Menninger, *Bl.* [3] 84, 195). Prisms.

**Tetra-chloro-iso-butane**  $CCl_2.CMe_2Cl$ . *Tri-chloro-tri-methyl-carbinyl chloride* or *chloro-isobutyro-tri-chloride*. (187°). Strong odour. Formed, together with hexa-chloro-di-*tert*-butyl oxide  $(CCl_2.CMe_2)_2O$ , by the action of  $PCl_5$  upon acetone-chloroform (Willgerodt a. Dürr, *B.* 20, 539).

**Hexa-chloro-butane**  $C_4H_2Cl_6$ . (148°) at 50 mm. S.G. 12 1.67. A liquid formed by the action of chlorine on isobutyl iodide (Pruvier, *Bl.* [2] 24, 24).

**Hexa-chloro-butane**  $C_4H_2Cl_6$ . Formed by the action of chlorine on  $C_4H_9Cl$  (from isobutyl alcohol) in sunlight (Puchot, *C. R.* 85, 757). Oil. Converted by KOH into  $C_4H_2Cl_6$ ,  $C_4Cl_6$ , and  $C_4Cl_8$ .

**Hexa-chloro-butane**  $C_4H_2Cl_6$ . (c. 115°) in *vacuo*. From *tert*-butyl chloride and chlorine in sunlight (d'O. de B.).

**Hepta-chloro-butane**  $C_4HCl_7$ . [86°]. (125°–185°) in *vacuo*. From *tert*-butyl chloride and Cl in sunlight (d'O. de B.).

Hepta-chloro-butane  $C_4H_3Cl_7$ . [42°]. (135°-145°) *in vacuo*. Formed at the same time as the preceding.

**CHLORO-BUTANE TETRA-CARBOXYLIC ACID**  $CCl(CO_2H)_3C(CO_2H)(CO_2H)_2$ . *Ethyl-chloroacetylene-tetra-carboxylic acid*.

*Tetra-ethyl-ether A-Et.* S.G.  $\frac{2}{3}$  1.076. Formed by chlorination of butane-tetra-carboxylic ether. Oil (Bischoff a. Rach, *B.* 17, 2786).

**CHLORO-BUTENYL ALCOHOL**  $C_4H_5ClO$ . *Chloro-crotyl alcohol*. (158-3° i.v.) at 742-6 mm. S.G.  $\frac{15}{16}$  1.1312. V.D. 8.60 (for 8.68). From tri-chloro-butyl alcohol by zinc-dust and HCl (Garzaroli-Thurnlackh, *A.* 213, 375). Crystallises in a freezing mixture. Smells like allyl compounds. M. sol. water, but separated by  $K_2CO_3$  or NaCl. Forms with Br in  $CHCl_3$ , chloro-dibromo-butyl alcohol, which is very unstable. If it be oxidised by  $HNO_3$ , it forms chloro-dibromo-butyric acid (not isolated) which is reduced by zinc-dust and HCl to chloro-crotonic acid [97°].

*Acetate* (168°-169°) at 741 mm. V.D. 5.23 (for 5.14). Colourless fruity liquid, heavier than water. V. sl. sol. water.

**CHLORO-BUTINENE**  $C_4H_3Cl$ . (65°). From di-chloro-butylene  $CH_3CH:CHCHCl_2$  and alcoholic KOH (Kekulé, *A.* 162, 99).

**Hexa-chloro-butene**  $C_4Cl_6$ . [39°]. (284°). From s-hexyl-iodide and  $ICl_3$  at 100°-240° (Krafft, *B.* 10, 803). Thin prisms (from alcohol).

#### TRI-CHLORO-BUTYL ACETATE

$C_4H_3Cl_3OAc$ . (217-5°) at 733 mm. S.G.  $\frac{55}{56}$  1.344. From tri-chloro-butyl alcohol and  $AcCl$  at 110° (Garzaroli-Thurnlackh, *A.* 213, 373).

**α-CHLORO-ISOBUTYL ALCOHOL**  $C_4H_9ClO$  i.e.  $(CH_3)_2CClCH_2OH$ . *Butylene-glycol chlorhydrin* (137°). From isobutylene and  $HClO$  (Butlerow, *A.* 144, 25). Sl. sol. water. Reduced by sodium-amalgam to isobutyl alcohol. Oxidised by  $HNO_3$  to chloro-isobutyric acid (Henry, *B.* 9, 1034).

**Chloro-sec-butyl alcohol**. *Ethyl ether*  $CH_3CH_2CH(OEt)CH_2Cl$ . (141°). S.G.  $\frac{2}{3}$  0.9735. From di-chloro-di-ethyl-oxide and  $ZnEt_2$  (Lieben, *A.* 223, 133).

**Di-chloro-tert-butyl alcohol**  $C_4H_9Cl_2O$ . (143-5° i.v.). S.G.  $\frac{2}{3}$  1.0335. From  $(CH_3)_3CCHCl$  and  $HClO$  (Oeconomides, *C. R.* 92, 1235).

**Tri-chloro-butyl alcohol**  $CH_3CCl_2CHClCH_2OH$  (62°). (120°) at 45 mm. From tri-chloro-butyric aldehyde (butyl chloral) and  $ZnEt_2$ ,  $ZnPr_2$ , or  $Zn(CH_3)_2$ , followed by water, thus:  $C_4H_3Cl_3CHO + Zp(C_2H_5)_2 = C_4H_3Cl_3CH_2OH + ZnCl_2$  (Garzaroli-Thurnlackh, *A.* 213, 370; 223, 166). Also from urochloric acid and HCl (Mering, *H.* 4, 93). Prisms (from ether). V. sol. alcohol or ether, sl. sol. hot water. Sol. warm conc.  $H_2SO_4$ , but decomposed by heating the solution.

**Reactions.**—1.  $PCl_5$  has hardly any action, 2. Fuming  $HBr$  at 110° has no action.—3.  $PCl_5$  gives tetra-chloro-butane.—4. Fuming  $HNO_3$  gives tri-chloro-butyric acid.—5. Zinc-dust and HCl reduce it to chloro-butenyl alcohol (*q. v.*).

**Tri-chloro-tert-butyl alcohol v. Acetone-chloroform**

**CHLORO-ISO-BUTYL-ISO-AMYL-GLYOXALINE (?)**  $C_{12}H_{21}ClN_3$ . *Chloro-oxalamylamine*. (267°-270°). Prepared from di-isoamyl-oxamide in the same way as chloro-oxalethylamine from di-ethyl-oxamide (Wallach a. Schulze, *B.* 68, 516; *A.* 214, 316).

**Salts.**—( $BHCl$ ),  $PCl_5$ ,  $BHCl$ .

**γ-CHLORO-*n*-BUTYL-BENZENE**  $C_{10}H_{17}Cl$  i.e.  $C_6H_5CH_2CHClCH_2CH_3$ . From  $C_6H_5CH(OH)C_3H_7$  and  $HCl$  (Engler a. Bethge, *B.* 7, 1128). Liquid.

**CHLORO-ISO-BUTYLENE**  $(CH_3)_2C=CHCl$ . *Isobutenyl chloride*. *Isocrotyl chloride*. (c. 65°). S.G.  $\frac{12}{13}$  0.979. V.D. 89.7. From isobutylidene chloride  $(CH_3)_2CHCHCl_2$  and alcoholic KOH or  $NH_3$ . Formed together with  $(CH_3)_2CHCHCl_2$ , by treating isobutyric aldehyde with  $PCl_5$  (Oeconomides, *C. R.* 92, 884, 1235; *Bl.* [2] 35, 498). Formed also by the action of chlorine on isobutylene, especially below 0° (Scheschukoff, *J. R.* 16, 493; *Bl.* [2] 41, 253; 43, 127). Converted by water at 90° into isobutyric aldehyde.

**Chloro-isobutylene**  $CH_3C(CH_3)=CHCl$ . *Butenyl chloride*. (c. 73°). S.G.  $\frac{2}{3}$  0.955. Formed, together with the preceding, by chlorinating isobutylene, especially above 0° (S.). Heated with aqueous  $K_2CO_3$ , it forms isobutenyl alcohol (113°).  $HCl$  forms  $C_4H_8Cl_2$  (107°), whence  $K_2CO_3$  gives  $C_4H_9(OH)_2$  (178°).

**Di-chloro-*n*-butylene**  $CH_3CH:CHCHCl_2$ . (126°). S.G.  $\frac{22}{23}$  1.131. From crotonic aldehyde and  $PCl_5$  (Kekulé, *A.* 162, 98). Alcoholic KOH gives  $C_4H_7Cl$  (65°) and  $C_4H_7ClOEt$  (134°). Br gives  $C_4H_8Cl_2Br$ , whence aqueous  $K_2CO_3$  gives  $C_4K_2ClBr(OH)_2$  (c. 118°).

**Tetra-chloro-butylene**  $C_4H_2Cl_4$ . (200°). From tri-chloro-butyric aldehyde and  $PCl_5$  (Judson, *B.* 3, 790).

**Penta-chloro-butylene**  $C_4HCl_5$ . (187°) at 460 mm. From *tert*-butyl alcohol and chlorine (Lieben, *B.* 8, 1017).

#### TRI-CHLORO-BUTYLIDENE-IMIDE

$CH_3CHClCCl_2CH:NH$  [164°-165°]. (P. a. K.); [170°] (S.). Prepared by the action of ammonium acetate on tri-chloro-butyric ortho-aldehyde (hydrate of butyrochloral) (Pinner a. Klein, *B.* 11, 1491). Also by heating tri-chloro-butyric aldehyde-ammonia with benzoic aldehyde (R. Schiff, *G.* 9, 438). Sol. alcohol, ether, hot water and hot benzene.

**α-CHLORO-ISO-BUTYL-MALONIC ACID**  $C_6H_9ClO_4$ . *Di-ethyl-ether A-Et.* (246°). S.G.  $\frac{12}{13}$  1.091. Prepared by the action of chlorine on isobutyl-malonic ether. Liquid. On saponification with KOH it gives iso-butyloxy-malonic acid (Conrad a. Bischoff, *B.* 13, 600; *A.* 209, 337).

**HEXA-CHLORO-DI-*tert*-BUTYL OXIDE**  $C_8H_2Cl_6O$  i.e.  $(CCl_3CMe_2)_2O$ . *Acetone-chloroform ether*. (156°). Formed, together with  $CCl_3CMe_2OH$ , and its oily isomeride, by the action of  $PCl_5$  upon acetone-chloroform (Willgerdt a. Dürr, *B.* 20, 539). Liquid. Volatile with steam. Very pungent.

**α-CHLORO-*n*-BUTYRIC ACID**  $C_5H_9ClO_2$  i.e.  $CH_3CH_2CHClCO_2H$ . From its chloride and water. Thick liquid, v. sol. hot water.

**Chloride**  $CH_3CH_2CHClCOCl$ . (c. 181°). S.G.  $\frac{12}{13}$  1.257. Formed by chlorinating butyryl chloride in presence of iodine (Markownikoff, *A.* 153, 241; cf. *Z.* [3] 4, 621).

**Ethyl ether** EtA'. (c. 158°). S.G. 1.068 (M.).

**$\beta$ -Chloro-*n*-butyric acid**  
CH<sub>3</sub>CHClCH<sub>2</sub>CO<sub>2</sub>H.

**Formation.**—1. By saponification of allyl cyanide by HCl (Pinner, B. 12, 2056).—2. By oxidation of the corresponding aldehyde (Karetnikoff, J. R. 11, 252).—3. By treating the hydrochloride of  $\beta$ -chloro-butyric imido-ether CH<sub>3</sub>CHClCH<sub>2</sub>C(NH)(OEt) with water (Pinner, B. 17, 2008).

**Reactions.**—Boiling baryta-water forms HCl and crotonic acid.

**Ethyl ether EtA'.** (c. 170°). S.G. 1.072 (Ba.); 1.0517 (Br.).  $\mu$  1.430.  $n_D^{20}$  59.1. Obtained by chlorinating butyric acid (Balbiano, B. 10, 1749; 11, 348; G. 10, 137). Probably the same compound is got by saturating an alcoholic solution of crotonic acid with HCl (Brühl, A. 203, 28). Converted by KOH into crotonic acid and  $\beta$ -oxy-butyric acid. Heated with alcoholic NH<sub>3</sub> it gives  $\beta$ -amido-butyramide.

**$\gamma$ -Chloro-butyric acid** CH<sub>3</sub>CH<sub>2</sub>CHClCH<sub>2</sub>CO<sub>2</sub>H. [10°]. S.G. 1.250. From the nitrile by HCl (Henry, C. R. 101, 1158). Viscous liquid or thin laminae, sl. sol. water. At 190° it splits up into HCl and the lactone of  $\gamma$ -oxy-butyric acid.

**Methyl ether MeA'.** (174°). S.G. 1.394. From the nitrile, MeOH, and HCl.

**Ethyl ether EtA'.** (184°). S.G. 1.122. Chloride CH<sub>3</sub>CHClCH<sub>2</sub>CH<sub>2</sub>COCl. (171°). S.G. 1.268.

**Amide** CH<sub>3</sub>CHClCH<sub>2</sub>CH<sub>2</sub>CONH<sub>2</sub>. [90°]. **Nitrile** CH<sub>3</sub>CHClCH<sub>2</sub>CH<sub>2</sub>CN. (196°). S.G. 1.162. From CH<sub>3</sub>CHClCH<sub>2</sub>CH<sub>2</sub>Br and KCy.

**$\alpha$ -Chloro-isobutyric acid** (CH<sub>3</sub>)<sub>2</sub>CClCO<sub>2</sub>H. From (CH<sub>3</sub>)<sub>2</sub>CClCHOH by oxidation with HNO<sub>3</sub> (Henry, B. [2] 26, 24). Formed also by chlorinating isobutyric acid (Balbiano, B. 11, 1693).

**Ethylether EtA'.** (149° cor.). S.G. 1.062. Converted by alkalis into oxy-isobutyric, methacrylic, and 'di-butyllactic' (C<sub>4</sub>H<sub>7</sub>O<sub>3</sub>) acids (Testa, G. 10, 377).

**$\alpha\beta$ -Di-chloro-butyric acid** CH<sub>3</sub>CHClCHClCO<sub>2</sub>H [63°]. Formed by combining solid crotonic acid with chlorine, in CS<sub>2</sub> solution. Large glistening colourless prisms. By aqueous NaOH at the ordinary temperature it is converted into *allo*- $\alpha$ -chloro-crotonic acid [66°]. If the solution is heated during the reaction some ordinary  $\alpha$ -chloro-crotonic acid is formed simultaneously. On heating the neutral alkaline salts in aqueous solution *allo*- $\alpha$ -chloro-propylene is formed (Wislicenus, B. 20, 1008; Michael & Brown, Ann. 9, 321, J. pr. [2] 36, 174; cf. Friedrich, A. 219, 371).

**Salts.**—AgA'.—BaA': gummy. **Methyl ether** MeA'. (84°) at 28 mm.; (177°). S.G. 1.2809 (Zeisel, M. 7, 368).

**Ethyl ether EtA'.** (96°) at 55 mm. Converted by alcoholic KOH into  $\alpha$ -chloro-crotonic acid [98°].

**Chloride** CH<sub>3</sub>CHClCHClCOCl. (164°). From crotonic aldehyde and chlorine (Z.).

***Allo*- $\alpha\beta$ -di-chloro-butyric acid** CH<sub>3</sub>CHClCHClCO<sub>2</sub>H. Liquid. Formed, together with some solid  $\alpha\beta$ -di-chloro-butyric acid [83°], by combination of liquid *iso*-crotonic acid with Cl. By excess of cold aqueous NaOH it is

converted into ordinary  $\alpha$ -chloro-crotonic acid [99°]. On heating the neutral aqueous solution of the alkaline salts, ordinary  $\alpha$ -chloro-propylene (36°) is formed (Wislicenus, B. 20, 1009).

A di-chloro-butyric acid is formed by chlorinating *n*-butyric acid in sunlight (Pelouze & Gélis, A. Ch. [3] 10, 434; Naumann, A. 119, 120).

**$\alpha\alpha$ -Di-chloro-butyric acid. Anilide.** CH<sub>3</sub>CH<sub>2</sub>CCl<sub>2</sub>O.NHPh. [200°]. From aniline ethyl-malonate and PCl<sub>5</sub> (Schramm, B. 21, 289). Distillation with aqueous Na<sub>2</sub>CO<sub>3</sub> converts it into NPh.CH<sub>2</sub>CH<sub>2</sub>CO.NHPh which yields phenylcarbamine when boiled with conc. KOH.

***o*-Toluide** CH<sub>3</sub>CH<sub>2</sub>CCl<sub>2</sub>O.NHCH<sub>3</sub>. Prepared in a similar way. Is converted by aqueous Na<sub>2</sub>CO<sub>3</sub> into NC<sub>6</sub>H<sub>4</sub>.CH<sub>2</sub>CH<sub>2</sub>CO.NHCH<sub>3</sub>. [107°].

**Tri-chloro-butyric acid** CH<sub>3</sub>CHClCCl<sub>2</sub>CO<sub>2</sub>H. [60°] (K.); [58°] (G.). (237°). S. 4. Formed by oxidising tri-chloro-butyric aldehyde (Krämer & Pinner, B. 3, 389; Judson, B. 3, 785; Kahlbaum, B. 12, 2337). From the alcohol and fuming HNO<sub>3</sub> (Garzaroli-Thurniacchi, A. 213, 374; 182, 185). The silver salt when boiled with water gives di-chloro-propylene (78°).—AgA'.—CaA'.—PbA'.

**Ethylether EtA'.** (212°). Chloride CH<sub>3</sub>CHClCCl<sub>2</sub>COCl. (c. 164°). Amide CH<sub>3</sub>CHClCH<sub>2</sub>CONH<sub>2</sub>. [96°].

**Tri-chloro-butyric acid** CH<sub>3</sub>CHClCCl<sub>2</sub>CO<sub>2</sub>H. (75°). S. 5. From the corresponding aldehyde and fuming HNO<sub>3</sub> (Natterer, M. 4, 539; 5, 251).

**Tri-chloro-isobutyric acid** C<sub>2</sub>H<sub>5</sub>Cl<sub>3</sub>O<sub>2</sub>. [50°]. Separates when chlorine is passed into an aqueous solution of sodium citraconate (Gottlieb, J. pr. [2] 12, 1). Prisms. Boiling alkalis convert it into di-chloro-methacrylic acid. Zinc-dust and HCl form chloro-methacrylic acid.

**Salts.**—NH<sub>4</sub>A'.—BaA'.—PbA'.—Aniline salt NH<sub>4</sub>PhA'. [164°] (Daccone, J. 1884, 1835).—[4.1]C<sub>6</sub>H<sub>5</sub>Me.NH<sub>4</sub>A'. [154°] (D.).

**Tetra-chloro-butyric acid** C<sub>2</sub>H<sub>2</sub>Cl<sub>4</sub>O<sub>2</sub>. [140°]. From *n*-butyric acid and Cl in sunlight (Pelouze & Gélis, A. Ch. [3] 10, 434).

**$\beta$ -CHLORO-*n*-BUTYRIC ALDEHYDE** C<sub>4</sub>H<sub>7</sub>ClO i.e. CH<sub>3</sub>CHClCH<sub>2</sub>CHO. [97°]. From crotonic aldehyde and gaseous HCl (Kekulé, A. 162, 100). Needles (from dilute alcohol); insol. water.

**Tri-chloro-butyric aldehyde** CH<sub>3</sub>CHClCCl<sub>2</sub>CHO.

**Butyl-chloral.** Mol. w. 175½. (165°). S.G. 1.3956.  $\mu$  1.482.  $n_D^{20}$  57.99 (Brühl, A. 203, 20).

**Formation.**—1. By the action of chlorine on aldehyde (Pinner, A. 179, 21; B. 3, 393; 8, 1561). 2. From chloro-acetic ortho-aldehyde by heating with an equivalent quantity of aldehyde and a trace of HCl; the oily product ( $\alpha$ -chloro-crotonic aldehyde) being subsequently chlorinated (Lieben & Zeisel, M. 4, 531).

**Properties.**—Liquid; combines with water forming a crystalline hydrate, whence it is liberated by distillation as a current of HCl. Oxidation gives tri-chloro-butyric acid. PCl<sub>5</sub> gives C<sub>2</sub>H<sub>2</sub>Cl<sub>4</sub> (200°).

**Reactions.**—1. ZnMe, in ether followed, after a time, by water gives tri-chloro-amyl alcohol (C<sub>5</sub>H<sub>9</sub>Cl<sub>3</sub>)CHMeOH.—2. ZnEt<sub>2</sub> (1 mol.) gives off ethylene, and the residue when treated with

water forms tri-chloro-butyl alcohol (Garzarolli-Thurnlackh, A. 213, 370).—3. Tri-chloro-lactic acid at 130° gives  $\text{CH}_2\text{CH}(\text{CO}_2)\text{CH}_2\text{CH}_2\text{Cl}$ , [107°] (Wallach, A. 193, 47).—4. Lactic acid gives  $\text{CH}_2\text{CH}(\text{CO}_2)\text{CH}_2\text{CH}_2\text{Cl}$ , (261%).—5. Tri-chloro-oxy-valeric acid at 175° slowly forms  $\text{C}_2\text{H}_4\text{CH}(\text{CO}_2)\text{CH}_2\text{CH}_2\text{Cl}$ , [85°]. (300°–310°) (W.).—6.  $\text{PHI}$  forms  $\text{C}_2\text{H}_3\text{Cl}_2\text{PO}_2$  [96°] (Girard, A. Gh. [6] 2, 52). Split up by conc.  $\text{NaOHAq}$  into  $\text{HCl}$ ,  $\text{H}_3\text{PO}_4$ ,  $\text{C}_2\text{H}_5\text{Cl}_2$ , formic acid and hydrogen.

**Combinations.**—1. With water?—*Tri-chloro-butyl ortho-aldehyde*  $\text{CH}_2\text{CHCl}_2\text{CHCl}_2\text{CH}(\text{OH})_2$ . Mol. w. 193. [78°] (K. a. P.); [75°] (L. a. Z.). V.D. 3.33 (calc. 6.7) (Moitessier, C. R. 90, 1075). Trimetric laminae; *abc* = 65:1:1.2. Dissociated by heat. **Reactions.**—(a) Converted by boiling  $\text{Na}_2\text{CO}_3\text{Aq}$  into di-chloro-propylene (77°) which on oxidation with  $\text{CrO}_3$  yields acetic acid.—(b)  $\text{Zn}$  and  $\text{HCl}$  reduce it to chloro-crotonic and crotonic aldehydes (Sarnow, A. 164, 108).—(c) Iron and  $\text{HOAc}$  give butyric aldehyde, *n*-butyric alcohol, and butenyl alcohol (Lieben a. Zeisel, M. 1, 840).—(d) After being taken into the system it is excreted in urine as tri-chloro-butyl-gly-crotonic acid  $\text{C}_2\text{H}_3\text{Cl}_2\text{CO}$  (Mering, H. 6, 491; Kütz, J. Th. 1882, 95). This acid crystallises in silky needles, is levorotatory, and split up by boiling dilute acids into glycuronic acid and tri-chloro-butyl alcohol.—(e) Heated with dry  $\text{NH}_4\text{OAc}$  it forms  $\text{C}_2\text{H}_3\text{Cl}_2\text{NH}$  [165°] (Pinner a. Klein, B. 11, 1491); [170°] (Schiff, B. 11, 2167).

2. With hydrogen cyanide:—*Tri-chloro-oxy-valeronitrile*  $\text{CH}_2\text{CHCl}_2\text{CHCl}_2\text{CH}(\text{CN})_2$ . [102°]. (c. 230°). This is converted by alcoholic  $\text{NH}_3$  into chloro-crotonamide; and by  $\text{H}_2\text{SO}_4$  into tri-chloro-oxy-valeramide. Heated with urea it yields chloro-crotonyl-urea  $\text{CH}_2\text{CHCl}_2\text{CO.NH.CO.NH}_2$  as chief product (about 60 p.c.) and butyro-chloral-biuret

$\text{CH}_2\text{CHCl}_2\text{CHCl}_2\text{CH}(\text{NH.CO})_2\text{NH}$  as a by-product (about 6 p.c.) (Pinner a. Lifschütz, B. 20, 2347).

3. With acetamide:— $\text{C}_2\text{H}_3\text{Cl}_2\text{OH}(\text{NHAc})$ . [170°] (Pinner, A. 179, 40); [158°] (Schiff a. Tassinari, B. 10, 1785). Tables; v. sl. sol. water.

4. With benzamide:— $\text{C}_2\text{H}_3\text{Cl}_2\text{OH}(\text{NHBz})$ . [150°] (Pinner, A. 179, 40); [133°] (Schiff a. Tassinari, B. 10, 1785). Formed by melting tri-chloro-butyl aldehyde with benzamide.

5. With carbamic ether:— $\text{C}_2\text{H}_3\text{Cl}_2\text{OH}(\text{NH.CO.OEt})$ . [125°]. From tri-chloro-butyl aldehyde, carbamic ether, and  $\text{HCl}$  (Bischoff, B. 7, 632). Small prisms.

6. With ammonia:—[62°] (S. a. T.).

7. With alcohol:—

$\text{CH}_2\text{CHCl}_2\text{CHCl}_2\text{CH}(\text{OH})(\text{OEt})$ . Oil (P.).

8. With acetyl chloride:—

$\text{CH}_2\text{CHCl}_2\text{CHCl}_2\text{CH}(\text{OAc})\text{Cl}$  (220°).

*Tri-chloro-butyl aldehyde*

$\text{CH}_2\text{ClCH}_2\text{CHCl}_2\text{CHO}$ . [78°]. From  $\alpha$ -di-chloro-crotonic aldehyde  $\text{CH}_2\text{ClCH}(\text{Cl})\text{CHO}$  and  $\text{HCl}$  (Natterer, M. 4, 551; 5, 253). Forms no hydrate.

**$\beta$ -CHLORO-BUTYRIMIDO-ETHYL-ETHER**  $\text{C}_2\text{H}_3\text{Cl}_2\text{C}(\text{NH})\text{OEt}$ . The hydrochloride is formed by passing  $\text{HCl}$  into a mixture of alkyl cyanide (1 mol.) and ethyl alcohol (1 mol.). The hydrochloride ( $\text{B}^{\text{HCl}}$ ) crystallises in large colourless prisms (Pinner, B. 17, 2007).

**CHLORO-CAFFEINE** v. **CAFFEINE**.

**CHLORO-CAMPHOR** v. **CAMPHOR**.

**CHLORO-CAPROIC ACID** v. **CHLORO-HEXOIC ACID**.

**CHLORO-TRICARBALLYLIC ACID**. *Methyl ether*  $\text{CH}_2(\text{CO}_2\text{Me})\text{CCl}(\text{CO}_2\text{Me})\text{CH}_2(\text{CO}_2\text{Me})$ . From tri-methyl citrate and  $\text{PCl}_5$  (Hanus, B. 9, 1750). Oil; split up by heat into  $\text{HCl}$  and tri-methyl acconitate.

**TRI-CHLORO-CARBAZOLE**  $\text{C}_{12}\text{H}_3\text{Cl}_3\text{N}$ . [180°]. Prepared by passing chlorine into acetic acid containing carbazole in suspension until the mass appears bright green (Gräbe, A. 202, 27). Needles; sol. benzene, ether, and alcohol. Its solution in conc.  $\text{H}_2\text{SO}_4$  is bright green. Its picric acid compound [f00°] forms red needles.

Hexa-chloro-carbazole  $\text{C}_{12}\text{H}_3\text{Cl}_6\text{N}$ . [225°]. Obtained by further chlorination of the above. Long needles; its solution in conc.  $\text{H}_2\text{SO}_4$  is yellowish-green.

Octo-chloro-carbazole  $\text{C}_{12}\text{HCl}_8\text{N}$ . [275°]. Formed by chlorinating the above in presence of  $\text{SbCl}_5$ . Long needles, sl. sol. alcohol. Further chlorination in presence of  $\text{SbCl}_5$  at 160° gives hexa-chloro-benzene.

**CHLORO-CARBONIC ETHER** v. **CHLORO-FORMIC ETHER**.

( $\beta$ )-**CHLORO-CARBOSTYRIL**  $\text{C}_8\text{H}_5\text{ClNO}$  i.e.  $\text{C}_6\text{H}_4\text{CH}(\text{COCl})\text{CH}_2\text{N}(\text{C}_6\text{H}_5)_2$  (Py. 2, 8). *Chloro-oxy-quinoline*. [242°]. Formed by heating di-chloro-quinoline [104°] with dilute  $\text{HCl}$  to 120°. By  $\text{PCl}_5$  it is converted back into the di-chloro-quinoline [104°] (Friedländer a. Weinberg, B. 15, 336, 2679).

*Ethyl ether*  $\text{C}_8\text{H}_5\text{ClN}(\text{OEt})$ : liquid, volatile with steam.

Chloro-carbostyryl  $\text{C}_8\text{H}_5\text{NOCl}$ . [246°]. Formed by boiling a dilute  $\text{HCl}$  solution of *o*-amido-phenyl-propionic acid (Baeyer a. Baum, B. 15, 2148). Sublimable. Silky needles. Sl. sol. hot, insol. cold, water. May be identical with the above.

Di-chloro-carbostyryl  $\text{C}_8\text{H}_3\text{Cl}_2\text{NO}$ . [249°]. Formed by chlorination of carbostyryl (Friedländer a. Weinberg, B. 15, 1425). Fine white needles.  $\text{PCl}_5$  converts it into tri-chloro-quinoline [161°].

**DODECA-CHLORO-CEROTIC ACID**  $\text{C}_{22}\text{H}_3\text{Cl}_{21}\text{O}_2$ . From cerotic acid and chlorine (Brodie, A. 67, 190). Gummy mass. **ETA**.

**CHLORO-CETYL ALCOHOL**  $\text{C}_{22}\text{H}_{43}\text{ClO}$ . (300°). From ceteric  $\text{C}_{22}\text{H}_{45}$  and cold dilute  $\text{HClO}$  (Carius, A. 126, 195). Liquid.  $\text{KOH}$  gives  $\text{C}_{21}\text{H}_{41}\text{O}$  [80°] (300°).

**DI-CHLORO-CHELIDAMIC ACID** v. **CHELIDONIC ACID**.

**HEPTA-CHLORO-CHOLESTERIN** v. **CHOLESTERIN**.

**CHLORO-CHROMIC ACID**. Name sometimes given to  $\text{CrO}_2\text{Cl}_2$  v. **CHROMIUM OXYCHLORIDES** of.

**CHLORO-CHRYSENE** v. **CHRYSENE**.

**$\alpha$ -CHLORO-CINNAMIC ACID**

$C_6H_5.OH.OCl.CO_2H$ . *α-Chloro-β-phenyl-acrylic acid*. [142°].

**Formation.**—1. By heating sodium chloroacetate with acetic anhydride and benzoic aldehyde (Plochl, *B.* 15, 1945).—2. By heating *α-chloro-β-oxy-β-phenyl-propionic acid* with  $NaOAc$  and  $Ac_2O$  (Forrer, *B.* 16, 854).—3. Together with a small quantity of the *β* isomeride by heating  $C_6H_5.CHCl.CHCl.CO_2H$  with alcoholic  $KOH$  (Jutz, *B.* 15, 788).—4. By digesting benzoyl-acetic ether with  $PCl_5$  and  $POCl_3$  at  $100^\circ$  (Perkin, *C. J.* 47, 240). In this reaction the *β* acid might have been anticipated. Needles. Volatile with steam. V. sol. sol. water, v. sol. alcohol and ether, sl. sol. ligroin.

*β-Chloro-cinnamic acid*  $C_6H_5.CCl.CH.CO_2H$ . ? *Allo-α-chlorocinnamic acid*. [114°]. Formed as above (Formation 3) and separated from the *α*-acid by the smaller solubility of its potassium salt in alcohol. Trimetric crystals (Haushofer, *Z. K.* 8, 382, 389).

*o-Chloro-cinnamic acid*

[2:1] $C_6H_4.Cl.CH.CH.CO_2H$ . [200°]. (G. a. H.); [196°] (S.). Formed by boiling *o*-diazocinnamic acid with strong  $HCl$  (Gabriel a. Herzberg, *B.* 16, 2030). Also by heating *o*-chloro-benzylidene-malonio acid to its melting-point (Stuart, *C. J.* 53, 141). Sol. alcohol, ether, and acetic acid, nearly insol. petroleum-ether and hot water.

*m-Chloro-cinnamic acid*

[3:1] $C_6H_4.Cl.O.H_2.CO_2H$ . [167°]. Formed by boiling *m*-diazocinnamic acid with strong  $HCl$  (G. a. H. *B.* 16, 2038). Needles. V. sol. hot water, hot alcohol and ether, sl. sol. benzene and petroleum-ether.

*p-Chloro-cinnamic acid*

[4:1] $C_6H_4.Cl.O.H_2.CO_2H$ . [242°]. Formed by boiling *p*-diazocinnamic acid with strong  $HCl$  (Gabriel a. Herzberg, *B.* 16, 2039). V. sol. alcohol, sl. sol. cold water, benzene, and ether.

*Di-chloro-cinnamic acid*  $C_6H_3Cl_2.CH.CH.CO_2H$  [1:3:6]. Formed by the action of  $Ac_2O$  and  $NaOAc$  on (*β*)-dichloro-benzoic aldehyde (Seelig, *A.* 237, 168). Fine needles (from dilute alcohol).

(*α*)-Tri-chloro-cinnamic acid

$C_6H_2Cl_3.CH.CH.CO_2H$  [1:3:4:6]. [201°]. Formed by acting on (*α*)-trichloro-benzoic aldehyde with acetic anhydride and sodium acetate (Seelig, *A.* 237, 151).

(*β*)-Tri-chloro-cinnamic acid

$C_6H_2Cl_3.CH.CH.CO_2H$  [1:2:3:6]. [185°]. Formed by the action of acetic anhydride and sodium acetate on (*β*)-tri-chloro-benzoic aldehyde (Seelig, *A.* 237, 151).

**CHLORO-CITRACONIC ACID**  $C_6H_5ClO_4$ . The salts of this acid are formed from the anhydride. The free acid, liberated by the addition of  $H_2SO_4$  to the barium salt, splits up at once into water and anhydride.  $Zn$  and  $HCl$  reduce it to pyrotartaric acid.

Salts.— $CaA$ .— $BaA$   $3\frac{1}{2}$  aq.— $BaA$   $4$  aq.— $PbA$ .— $AgHA$ .— $AgA$ .

**Anhydride**  $C_6H_5ClO_4$ . [99°]. (212°). Formed by distilling citra-di-chloro-pyrotartaro or chloro-citramalic acid (Gottlieb, *J. pr.* [2] 8, 73; Swarts, *J.* 1873, 582). Laminæ; may be sublimed. Sl. sol. water, v. sol. alcohol and ether.

**CHLORO-CITRIC ACID**  $C_6H_5ClO_4$ . From acconitic acid and  $HOCl$  (Pawlolek, *A.* 178, 155).

Unstable syrup. Boiling with water or baryta-water gives oxy-citric acid.

**CHLORO-CODEINE v. CODEINE.**

**CHLORO-COMPOUNDS.** See also Bromo-Compounds. In organic compounds chlorine can displace hydrogen atom for atom, the resulting compound possessing as a rule considerable resemblance to the parent substance. This observation in the hands of Laurent and Dumas overthrew the electro-chemical theory of chemical affinity which had been established by Berzelius (cf. *K.* 1, 66). The hydrogen that is displaced by chlorine is usually that attached to carbon. Chlorination may be effected by a mixture of  $KClO_3$  and  $HCl$ , by  $PCl_5$ ,  $SbCl_5$ , or  $AcCl$ , but it is usually effected by the direct action of chlorine gas. The chlorination of aromatic hydrocarbons may be effected by heating the hydrocarbons with the theoretical amount of  $PCl_5$  at  $190^\circ$ ; in this case the  $PCl_5$  splits up into  $PCl_3$  and chlorine, the latter then attacking the side chains; the products are nearly pure (Colson a. Gautier, *Bl.* [2] 46, 6; *C. R.* 101, 1064). In the same way acetyl chloride heated for several weeks with  $PCl_5$  in an open flask is converted into chlorinated acetyl chlorides (Michael, *Am.* 9, 215). Acetyl chloride itself may be used as a chlorinating agent; thus benzene-azo-benzene heated with  $AcCl$  at  $170^\circ$  for 4 hours is converted into *p*-chloro-benzene-azo-chloro-benzene and *p*-chloro-acetanilide (Becker, *B.* 20, 2006). When free chlorine is used the substitution is usually slow unless it is aided by daylight, by sunlight, by heat, or by carriers.

Sunlight enables chlorine to enter the side chains of aromatic hydrocarbons even at  $0^\circ$  (Schramm, *B.* 18, 1272), which it will otherwise only do at a high temperature; in the cold and in the dark it only enters the benzene nucleus. Chlorine enters the methyl group of acetophenone whether the action take place in daylight or in the dark; the chlorination is, however, much more rapid in daylight (Gautier, *C. R.* 104, 1714).

Carriers. Iodine greatly assists chlorination, probably forming  $ICl$ , which reacts more vigorously than chlorine alone (Hugo Müller, *C. J.* 15, 41). The chlorides of metals which form two chlorides also act as carriers; e.g.  $SbCl_3$  (Hugo Müller; Beilstein a. Geitner, *A.* 139, 334; Ruoff, *B.* 9, 1456),  $MoCl_3$  (Aronheim, *B.* 8, 1400; 9, 1788; Page, *A.* 225, 199),  $FeCl_3$ ,  $AlCl_3$ ,  $TiCl_3$  and the chlorides of  $Au$ ,  $Sn$ ,  $Bi$ ,  $S$ ,  $Te$ ,  $Ga$ ,  $Zr$ ,  $Nb$ ,  $In$ ,  $Ta$ , and  $U$ . On the other hand the chlorides of  $Na$ ,  $K$ ,  $Li$ ,  $Ag$ ,  $Cu$ ,  $Ca$ ,  $Ba$ ,  $Sr$ ,  $Mg$ ,  $Zn$ ,  $Hg$ ,  $B$ ,  $P$ ,  $As$ ,  $Se$ ,  $Y$ ,  $Ce$ , and  $Di$  are not carriers (Willgerodt, *J. pr.* [2] 34, 264; 85, 398). According to Page, however, the chlorides of  $Sn$ ,  $S$ , and  $Bi$  are not carriers, as is also the case with the chlorides of  $Ti$ ,  $Cr$ ,  $W$ ,  $Mn$ ,  $Co$ , and  $Ni$ . It is, however, not possible to draw an absolute line of demarcation between carriers and non-carriers; the weaker carriers can only attack substances prone to chlorination. The effect of various chlorides is modified by circumstances, such as their solubility in the substance to be chlorinated, their stability in presence of water, and the temperature of the reaction.  $MoCl_3$  acts as a carrier of chlorine to aromatic bodies only and not to fatty compounds. It may be supposed that these various carriers act by

alternately giving up chlorine to the compound and taking it up again:

This does not account for the fact that carriers promote entrance into the benzene nucleus, nor for the observation that no ferrous chloride is formed when benzene is heated with  $\text{FeCl}_3$ . An alternative supposition is that in the case of aromatic bodies a molecular compound is first formed, possibly aided by the somewhat unsaturated condition of the benzene ring, and that this molecular compound is subsequently decomposed by chlorine.

Displacement of one halogen by another. Iodo-compounds may be converted into chloro-compounds by digestion with  $\text{HgCl}_2$ ; on the other hand, chloro-compounds may be changed to iodo-compounds by treatment with KI or, better,  $\text{CaI}_2 \cdot \text{H}_2\text{O}$ . Even acetyl chloride may be converted into acetyl iodide by heating with crystallised calcium iodide, without being affected by the water of crystallisation. In general, metals with low atomic weights prefer the lighter halogens. The following elements prefer chlorine to bromine or iodine, and bromine to iodine; viz., K, Mg, Ca, Sr, Ba, Al, Mn, Co.

On the other hand, Cu, Ag, Hg, Sn, Pb, As, and Sb prefer iodine to bromine or chlorine, and bromine to chlorine. P and Ti are indifferent. The metals Zn, Cd, Tl, Bi, Fe, and Ni are variable in their behaviour (Köhnelein, A. 225, 194).

Thus *n*-propyl iodide is not acted on by  $\text{MgCl}_2$ ,  $\text{SrCl}_2$ , or  $\text{BaCl}_2$ ; it is split up into gas and HI by  $\text{MnCl}_2$  and  $\text{TiCl}_4$ ; it is but slightly affected by  $\text{FeCl}_3$ ,  $\text{CoCl}_2$ , and  $\text{NiCl}_2$ ; but it is converted into propyl chloride by  $\text{ZnCl}_2$ ,  $\text{CdCl}_2$ ,  $\text{SnCl}_4$ ,  $\text{SnCl}_2$ ,  $\text{SbCl}_3$ , and  $\text{TiCl}_4$ .

*n*-Propyl chloride is converted into propyl iodide by  $\text{CaI}_2$ ,  $\text{SrI}_2$ ,  $\text{MnI}_2$ , and  $\text{CoI}_2$ ; is but slightly affected by  $\text{FeI}_3$  and  $\text{NiI}_2$ ; and is not affected by  $\text{SnI}_4$ .

The substitution of chlorine by iodine may be effected by the use of KI in the case of chloro-lactic acid, chloro-acetone, di-chloro-acetone, epichlorohydrin, and dichlorohydrin; on the other hand, KI does not act on dichlorinated ethyl oxide, and decomposes chloral into chloroform and CO.

The substitution of Cl by I may be effected by  $\text{AlI}_3$  in the case of  $\text{CCl}_4$  and  $\text{CH}_3\text{CHCl}_2$ ; but  $\text{AlI}_3$  does not act on  $\text{C}_2\text{Cl}_4$  or on  $\text{C}_2\text{Cl}_2$ , while it splits up  $\text{C}_2\text{Cl}_6$  into  $\text{C}_2\text{Cl}_4$  and  $\text{Cl}_2$ .

KBr converts di-chloro-acetone into di-bromo-acetone.  $\text{AlBr}_3$  converts  $\text{CCl}_4$ ,  $\text{C}_2\text{Cl}_4$ , and  $\text{C}_2\text{Cl}_2$  into  $\text{CBr}_4$ ,  $\text{C}_2\text{Br}_4$ , and  $\text{C}_2\text{Br}_2$ , respectively.

The conversion of EtI into EtCl is not effected by  $\text{BaCl}_2$ ,  $\text{CuCl}_2$ , or  $\text{PbCl}_2$  at  $72^\circ$ , but is partially brought about by  $\text{BaCl}_2$  at  $140^\circ$ , and is completely effected by  $\text{CaCl}_2$  and  $\text{PbCl}_2$  at  $160^\circ$ . The observation of Henry (C. R. 96, 1062) that silver nitrate converts ethylene chlorobromide  $\text{CH}_2\text{ClCH}_2\text{Br}$  into chloro-ethyl nitrate  $\text{CH}_3\text{CH}_2\text{CH}_2\text{O}_2\text{NO}$ , is in accordance with the statement made above, that silver prefers bromine to chlorine. Chlorine may be displaced by iodine by heating with conc.  $\text{HIAc}$  in sealed tubes, but the resulting iodo-compound is, especially in the case of aromatic compounds, liable to loss of iodine in exchange for hydrogen; thus chlorobenzenes are reduced to benzene by HI at  $250^\circ$

without any iodo-benzenes being formed (Berthelot, B. [2] 9, 80).

#### Chlorinated hydrocarbons.

**Formation.**—1. By chlorination of hydrocarbons. Chlorine enters the  $\alpha$  and  $\beta$  positions in fatty hydrocarbons; thus *n*-pentane gives

and  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CHClCH}_3$ . On further chlorination, the chlorine turns out hydrogen that is attached to the same atom of carbon as the chlorine atom already present. In the case of aromatic hydrocarbons chlorine enters the side chain only at a high temperature or in sunlight.

In presence of iodine or  $\text{SbCl}_5$ , it enters the benzene nucleus even at boiling temperature (*v. supra*). The rules relating to substitution in the benzene nucleus are given in the article BENZENE. The displacing action of chlorine is not confined to hydrogen; thus it can convert nitro-benzene into  $\text{C}_6\text{Cl}_5$  (Page, A. 225, 208).—2. Mono-chlorinated hydrocarbons or alkyl chlorides are formed by treating alcohols with  $\text{HCl}$ ,  $\text{PCl}_5$ ,  $\text{PCl}_3$ , or  $\text{POCl}_3$ . The action of  $\text{HCl}$  on alcohols is promoted by  $\text{ZnCl}_2$  (Groves, C. J. 27, 636; A. 174, 372; Krüger, J. pr. [2] 14, 195), but in the case of the higher fatty alcohols the resulting chloride is sometimes mixed with an isomeride derived from the olefine formed by dehydration of the alcohol (Schorlemmer, C. J. 28, 308; D. 7, 1792). The polyhydric alcohols will not exchange all their hydroxyls for Cl by treatment with  $\text{HCl}$  but require the use of  $\text{PCl}_5$ .—3. From olefines and  $\text{HCl}$ ; the chlorine attaching itself to the atom of carbon that is combined with the fewer hydrogen atoms. Di-chlorinated hydrocarbons are formed by the union of Cl with olefines, or of  $\text{HCl}$  with the hydrocarbons  $\text{C}_n\text{H}_{n-2}$ . Although chlorine combines with olefines in the dark, its combination with benzene and acetylene requires light (Römer, A. 233, 172).—4. From aldehydes or ketones and  $\text{PCl}_5$ .—5. From aromatic amines by the diazo-reaction (*v. Dr-Azo-compounds and Amines*). The conversion may also be effected by gradually adding  $\text{HNO}_3$  to a hot solution of the amine in  $\text{HCl}$  (Losanitsch, B. 13, 39).

**Reactions.**—1. Boiling water very slowly decomposes chlorinated hydrocarbons; the chlorides of tertiary alkyls are the most readily affected (Niedorist, A. 183, 388). Presence of  $\text{Ph(OH)}$ , or  $\text{E}_2\text{CO}$ , in the water promotes the conversion of chlorinated hydrocarbons into alcohols. If two chlorine atoms are attached to the same carbon atom, the product is an aldehyde or ketone; if three are attached to the same carbon atom, the product is an acid.—2. *Ammonia* converts the alkyl chlorides into amines. 3. *Alcoholic potash* removes  $\text{HCl}$  in two stages from di-chlorinated hydrocarbons, the Cl and H being detached from neighbouring carbon atoms, the hydrogen coming from the carbon atom to which the less hydrogen is attached.—4. Chlorine may be displaced by hydrogen by treatment with sodium-amalgam in presence of dilute alcohol; with zinc-dust and  $\text{HOAc}$ ; or with conc.  $\text{HIAc}$ .—5. Dry *oxalic acid* displaces chlorine by oxygen in the compounds  $\text{ROHCl}$  and  $\text{RCOCl}$  (Anschütz, A. 226, 18).

#### Chlorinated acids.

**Formation.**—1. By direct chlorination; chlorine taking the  $\alpha$  position if possible, especially

if the temperature be not above 100° (Erlenmeyer, *B.* 14, 1818).—2. From salts of oxy-acids and  $\text{PCl}_5$ , the resulting chlorinated alkyl chloride being decomposed by water.—3. By addition of chlorine, or of  $\text{HCl}$  to unsaturated acids;  $\text{HCl}$  uniting with acids of the form  $\text{ROH}:\text{CH}:\text{CO}_2\text{H}$  gives rise chiefly to  $\beta$ -chloro-acids.  
 $\text{ROHCl}:\text{CH}:\text{CO}_2\text{H}$

**Reactions.**—1. Boiling with water or alkalis usually converts  $\alpha$ -chloro-acids into oxy-acids,  $\beta$ -chloro-acids into unsaturated acids, and  $\gamma$ -chloro-acids into lactones. The  $\beta$ -chloro-acids also split up into  $\text{HCl}$ ,  $\text{CO}_2$ , and an olefine (Fittig, *A.* 145, 169; cf. Erlenmeyer, *B.* 14, 1818; 15, 49).  $\text{KOH}$  converts  $\alpha$ -chloro-acids into ethoxy-acids.  $\alpha,\alpha$ -di-chloro-acids are but slightly affected by boiling water;  $\alpha,\beta$ -di-chloro-acids give the chloro-oxy-acid, and also split off  $\text{CO}_2$ . Alcoholic  $\text{KOH}$  converts acids of the form  $\text{ROHCl}:\text{CHCl}:\text{CO}_2\text{H}$  chiefly into  $\text{ROH}:\text{C}(\text{Cl})\text{CO}_2\text{H}$ .  
 • Acid chlorides.

**Formation.**—1. By the action of  $\text{PCl}_5$ ,  $\text{PCl}_3$ , or  $\text{POCl}_3$  on the acid or on a dry salt of the acid (Gerhardt, *A.* 87, 63; Béchamp, *C. R.* 40, 944; Kanonnikoff, *A.* 175, 378). Although  $\text{PCl}_5$  does not convert tri-chloro-methane-sulphonic acid into its acid chloride, it acts upon methane sulphonic acid and chloro-methane sulphonic acid in the usual way.—2. By the action of  $\text{HCl}$  on a mixture of the acid and  $\text{P}_2\text{O}_5$  (Friedel, *Z.* 1869, 489).

**Reactions.**—1. Quickly decomposed by water into  $\text{HCl}$  and the corresponding acid, and even more readily decomposed by alcohols with formation of ethers.—2. Ammonia forms amides; primary amines act similarly.—3. Salts of organic acids form anhydrides. Dry oxalic acid also converts them into anhydrides (Anschütz, *A.* 226, 18; v. ANHYDRIDES, ORGANIC).—4. Zinc ethyl unites with them forming compounds such as  $\text{R}:\text{C}(\text{OZnEt})\text{EtCl}$  which are converted by water into ketones  $\text{R}:\text{CO}:\text{Et}$ ; further action of zinc ethyl forms  $\text{R}:\text{C}(\text{OZnEt})\text{Et}$ , whence water forms tertiary alcohols  $\text{R}:\text{C}(\text{OH})\text{Et}$ . Thus  $\text{CO}_2\text{Et}:\text{COCl}$  becomes  $\text{CO}_2\text{Et}:\text{C}(\text{OH})\text{Et}$  (Henry, *B.* 5, 949).—5. Aluminium chloride forms with acetyl chloride diluted with  $\text{CS}_2$  a white solid  $\text{C}_6\text{H}_5\text{O}_2\text{AlCl}$ , decomposed by water into  $\text{CH}_3\text{CO}:\text{CH}_2\text{CO}:\text{OH}$ , with evolution of  $\text{CO}_2$ , and by alcohol into acetyl-aceto-acetic ether.  $\text{AlCl}_3$  acts similarly on chlorides of other normal fatty acids (Combes, *A. Ch.* [6] 12, 199).—6. Chlorine acts by substitution more vigorously upon acid chlorides than upon the acids themselves (Jazukowitsch, *Z.* 1868, 234).—7. Sodium amalgam added to a mixture of an acid with its chloride reduces the latter to the corresponding alcohol (Linnemann, *A.* 161, 184; Baeyer, *B.* 2, 407).

Chloroamides and thloroimides  $\text{R}'\text{NHCl}$ ,  $\text{R}'\text{R}''\text{NCl}$ ,  $\text{R}'\text{NCl}$  where  $\text{R}'$ ,  $\text{R}''$  and  $\text{R}''$  are acid radicals, and  $\text{R}'$  acid or alcoholic.

These bodies are formed by adding a conc. solution of chloride of lime to the solution of the amide or imide acidified with  $\text{AcOH}$ .

By treatment with alkalis,  $\text{HCl}$  &c., their  $\text{Cl}$  atom is readily replaced by  $\text{H}$  (Bender, *B.* 19, 2272).

#### CHLORO-CUMARINE o. COMINE.

( $\alpha$ )-CHLORO-CUMARIN  $\text{C}_9\text{H}_7\text{ClO}_2$  [123°]. From coumarin and  $\text{PCl}_5$  at 200°. Also from coumarin dichloride and alcoholic  $\text{KOH}$  (Perkin,

*C. J.* 24, 43). Flat needles, m. sol. alcohol, sl. sol. hot water. Converted by alcoholic  $\text{KOH}$  into coumarilic acid.

( $\beta$ )-Chloro-coumarin  $\text{C}_9\text{H}_7\text{ClO}_2$  [162°]. From  $\text{Ac}_2\text{O}$  and sodium chloro-o-oxy-benzoic aldehyde  $\text{C}_6\text{H}_4\text{Cl}(\text{ONa})\text{CHO}$  (Bäsecke, *A.* 154, 85). Crystals, sl. sol. cold alcohol, v. e. sol. benzene. Boiling  $\text{KOH}$  converts it into chloro-coumaric acid.

Tetra-chloro-coumarin  $\text{C}_9\text{H}_3\text{Cl}_4\text{O}_2$  [145°]. Formed by passing chlorine into coumarin dissolved in  $\text{CCl}_4$  containing iodine (P.). Small needles (from alcohol).

CHLORO-p-CRESOL  $\text{C}_6\text{H}_4(\text{CH}_3)\text{Cl}(\text{OH})$  [1:3:4] (196°). S.G.  $\frac{2}{3}$  1.2108. Formed by the action of dry chlorine on sodium-p-cresol (Schall a. Drätle, *B.* 17, 2528). Liquid.

Methyl ether  $\text{C}_6\text{H}_4(\text{CH}_3)\text{Cl}(\text{OMe})$ . (214°). S.G.  $\frac{2}{3}$  1.1493. Liquid.

Chloro-cresol  $\text{C}_6\text{H}_4(\text{CH}_3)\text{Cl}(\text{OH})$  or  $\text{C}_6\text{H}_4(\text{CH}_3\text{Cl})(\text{OH})$ . [56°]. (c. 240°). Formed by chlorination of boiling crude cresol (Biedermann, *B.* 3, 325). Needles; v. sol. alcohol, ether, and benzene.

Chloro-cresol. Ethyl ether  $\text{C}_6\text{H}_4(\text{CH}_3)\text{Cl}(\text{OEt})$ . (c. 215°). S.G.  $\frac{2}{3}$  1.127. From ( $\alpha$ )-chloro-nitro-toluene by reduction, diazotisation, and treatment of the diazo-sulphate with boiling alcohol (Wroblewski, *A.* 188, 209).

Chloro-cresol. Ethyl ether  $\text{C}_6\text{H}_4(\text{CH}_3)\text{Cl}(\text{OEt})$ . (c. 215°). S.G.  $\frac{2}{3}$  1.131. From ( $\beta$ )-chloro-nitro-toluene in the same way as the preceding (W.).

Di-chloro-p-cresol  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}_2(\text{OH})$  [30° uncor.]. Formed by passing chlorine into boiling p-cresol (Claus a. Riemann, *B.* 16, 1598). Long prismatic needles. Sol. alcohol and ether, sl. sol. hot water. By  $\text{CrO}_3$  in acetic acid it is oxidised to di-chloro-p-oxy-benzoic acid [156° uncor.].— $\text{ANH}_2$ : long colourless needles [125°], sublimable.

Di-chloro-m-cresol  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}_2(\text{OH})$ ; probably [1:4:6:8]. [46° uncor.]. Formed by chlorinating m-cresol (Claus a. Schweitzer, *B.* 19, 930). Colourless needles. Volatile with steam. V. e. sol. alcohol, ether, &c., sol. hot water, nearly insol. cold. It is oxidised by  $\text{K}_2\text{Cr}_2\text{O}_7$  and dilute  $\text{H}_2\text{SO}_4$  to di-chloro-toluquinone [103°].

Di-chloro-o-cresol  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}_2(\text{OH})$  [1:5:3or4:2] [54° uncor.]. Formed by chlorination of o-cresol (C. a. R., *B.* 16, 1600). Large colourless needles. V. sol. alcohol, ether, benzene, chloroform and  $\text{CS}_2$ , sol. hot water, sl. sol. cold water. By  $\text{CrO}_3$  and glacial acetic acid it is oxidised to a mixture of di- and tri-chloro-toluquinone. By  $\text{K}_2\text{Cr}_2\text{O}_7$  and dilute  $\text{H}_2\text{SO}_4$  it is oxidised to mono-chloro-toluquinone [90°] (Claus a. Schweitzer, *B.* 19, 927).

Ezo-Di-chloro-o-cresol  $\text{C}_6\text{H}_3(\text{CHCl}_2)(\text{OH})$  [1:2]. [82°]. From salicylic aldehyde (1 mol.) and  $\text{PCl}_5$  (1 mol.) (Henry, *B.* 2, 185). Prisms (from ether); v. sl. sol. cold alcohol.

#### Phosphoryl derivative

$\text{PO}(\text{O}:\text{C}_6\text{H}_4\text{CHCl}_2)_2$  [78°]. From salicylic aldehyde and  $\text{PCl}_5$  (Stuart, *C. J.* 53, 402). Needles (from alcohol). Not affected by boiling dilute  $\text{NaOH}$  aq.

Methyl ether  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{OMe})_2$  [231°]. From  $\text{C}_6\text{H}_4(\text{OMe})\text{CHO}$  [1:2] and  $\text{PCl}_5$  (Stuart, *C. J.* 53, 401). Oil. Decomposed in moist air.

**Tri-chloro-cresol**  $C_6H_3Cl_3(OH)$ . [96°]. (270°). One of the products of distillation of crude penta-chloro-thymol (Lallemand, *J.* 1856, 620). Crystals; insol. water, sol. alcohol and alkalis.

**Tetra-chloro-cresol**  $C_6H_2Cl_4(OH)$ . [150°]. Obtained by distilling pure penta-chloro-thymol (L.). Needles.

**CHLORO-CROTONIC ACID**  
 $CH_2CHClCO_2H$ . [97-5°]. (206°) (Kahlbaum, *B.* 12, 2385; [212°] (Sarnow). S. 1-97 at 12° (K); 2-12 at 10° (Michael a. Brown, *Am.* 9, 283).

**Formation**.—1. From tri-chloro-butyric aldehyde by oxidation and treatment of the resulting tri-chloro-butyric acid with zinc and HCl (Krämer a. Pinner, *A.* 158, 37) or with zinc-dust and water (Sarnow, *A.* 164, 93; *B.* 4, 731; 5, 467).—2. By boiling tri-chloro-butyric aldehyde (29 g.) with  $K_2FeCy_4$  (42 g.) and water (500 g.) (Wallach, *B.* 10, 1530).—3. From solid crotonic acid by addition of chlorine followed by heating the product  $CH_2CHClCHClCO_2H$  (Friedrich, *A.* 219, 373).—4. From chloro-butenyl alcohol (*q. v.*) by oxidation.—5. By the action of cold aqueous NaOH upon the liquid *allo-a*-di-chloro-butyric acid (the addition product of isocrotonic acid and Cl) (Wislicenus, *B.* 20, 1009).

**Properties**.—Small flat needles; may be sublimed. Volatile with steam. Not attacked by alkalis below 220°, at which temperature acetic and oxalic acids are formed, together with  $CO_2$  and a syrupy acid (F.). Reduced by sodium-amalgam to crotonic acid.

**Salts**.—A'K: pearly plates or tables (from 80 p.c. alcohol); nearly insol. absolute alcohol.— $NH_4A'$ : laminae.— $CaA'_2$ :— $BaA'_2$ : laminae.— $PbA'_2$ , aq.— $CuA'_2$ : needles.— $CuA'(OH)$ : amorphous.— $AgA'$ : needles.

**Methyl ether** MeA'. (161°). S.G. 1.0933 (14589) (Kahlbaum, *B.* 12, 344).

**Ethyl ether** EtA'. (177° uncor.). S.G. 1.129. From tri-chloro-butyric aldehyde and alcoholic KCN (Wallach a. Böhrringer, *A.* 173, 301, cf. Claus, *A.* 191, 63). Turns brown in light.

**Reactions**.—1. Treated with KCN (2 mol.) and boiling alcohol it forms a product whence boiling KOH produces tri-carballylic acid (Claus, *B.* 191, 64) and crotonic acid,  $C_4H_7(CO_2H)_2$ , isomeric with itaconic acid. The tricarballylic acid is formed through addition of HCN to the crotonic acid.—2. With KCN (2 mol.) and dilute alcohol in the cold it forms potassic cyano-crotonate (*q. v.*) only.

**Chloride**— $CH_2CHClCOCl$ . (142°) (S.).

**Amide**  $CH_2CHClCONH_2$ . [112°] (P. a. K.); [107°] (S.). (c. 236°) (S.). From the cyanhydrin of tri-chloro-butyric aldehyde and alcoholic  $NH_3$  or dry ammonium carbonate (Pinner a. Kleff, *B.* 11, 1488). Also from the chloride and  $NH_3$  (S.). Laminae; may be sublimed.

**Nitrile**  $CH_2CHClCN$ . (136°). From the amide and  $P_2O_5$  (S.).

**Allo-a-chloro-crotonic acid**  $CH_2CHClCO_2H$ . [67°]. S. 6-53 at 10°. Formed by the action of an excess of aqueous NaOH upon *a*-di-chloro-butyric acid [68°] at the ordinary temperature (Wislicenus, *B.* 20, 1009; Michael a. Brown, *Am.* 9, 283). Slender needles (from water). More soluble in water than any of the other

chloro-crotonic acids; sl. sol. cold ligroin.—A'K: concentric needles; v. sol. absolute alcohol (difference from the *a*-acid, whose K-salt is nearly insoluble).— $BaA'_2$ , 3: aq.: crystals, sl. sol. alcohol.— $PbA'_2$ , aq.: prisms, sl. sol. water.— $AgA'$ : amorphous.

***$\beta$* -Chloro-crotonic acid**  $CH_2CClCHCO_2H$ . [94-5°]. (c. 209°). S. 1-9 at 19° (Michael a. Brown, *Am.* 9, 283); 2-25 at 12° (K); 2-8 at 19° (S.).

**Formation**.—1. The chloride of this acid is formed together with that of *allo- $\beta$* -chloro-crotonic acid by the action of excess of  $PCl_5$  on aceto-acetic ether. The mixed chlorides are saponified by water and the product distilled, whereupon  *$\beta$* -chloro crotonic acid passes over first (Geuther, *Z.* 1871, 237).—2. From tetrolic acid and fuming HCl (Friedrich, *A.* 219, 370).

**Properties**.—Slender monoelinic needles; *a:b:c* = 1:2859:1:6105;  $\beta$  = 73° 9'; volatile with steam; may be sublimed at 100°. At 160° it slowly changes into *allo- $\beta$* -chloro-crotonic acid.

**Reactions**.—1. Sodium amalgam gives crotonic acid.—2. Boiling aqueous potash (7 p.c.) gives tetrolic acid (K.).—Stronger potash (18 p.c.) gives chiefly acetone.—3. Sodium ethylate gives the same ethoxy-crotonic acid as is got from *allo- $\beta$* -chloro-crotonic acid.

**Salts**.— $NaA'$  aq.: thin laminae, v. e. sol. water.— $BaA'_2$ : trimetric octahedra. S. 45 at 18°.— $CuA'_2$ , aq.

**Ethyl ether** EtA'. (184° cor.). S.G. 1.111 (G.).

***Allo- $\beta$* -chloro-crotonic acid**  
 $CH_2CClCHCO_2H$ . [59-5°]. (195° cor.). S. 1-12 at 7°. Formed from aceto-acetic ether as above described (Geuther a. Fröhlich, *Z.* 1869, 270). Formed also by heating the preceding acid for 20 hours at 160° (Friedrich, *A.* 219, 363).

**Properties**.—Slender needles or prisms; volatile with steam; sublimed even at 20°. Not affected by boiling aqueous KOH.

**Reactions**.—1. Alcoholic KOH converts it into the ethyl derivative of *allo- $\beta$* -oxy-crotonic acid.—2. Conc. KOH aq. forms acetone and  $CO_2$ , a small quantity of tetrolic acid  $C_4H_5O_4$  [75°-77°] being also formed (Friedrich, *A.* 219, 341). Dilute KOH behaves similarly, but the tetrolic acid is the chief product.

**Salts**.— $NaA'$  aq.: satiny crystals, v. sol. water.— $KA'$  aq.— $TiA'$  aq.— $NH_4A'$  aq.— $CaA'_2$ , 3aq.— $BaA'_2$ , 2aq.: four-sided prisms.— $MgA'_2$ , 5aq.— $ZnA'_2$ , 2aq.— $PbA'_2$ , 4aq.— $MnA'_2$ , 2aq.— $CoA'_2$ , 6aq.— $NiA'_2$ , 6aq.— $CuA'_2$ , 1:1aq.— $AgA'$ .  
**Methyl ether** MeA'. (142° cor.). S.G. 1.143.

**Ethyl ether** EtA'. (161° cor.). S.G. 1.113. Boiling alcoholic KCN followed by KOH converts it into tri-carballylic acid (Claus a. Lischke, *B.* 14, 1089).

**Isomeride of chloro-crotonic acid v. CHLORO-METHACRYLIC ACID.**

***a*-Di-chloro-crotonic acid**  
 $CH_2CClCHClCO_2H$ . From *a*- $\beta$ -tri-chloro-butyric acid (1 mol.) and KOH (2 mols.) (Garzaroli, *B.* 9, 1209).

***a*-CHLORO-CROTONIC ALDEHYDE**  
 $CH_2CHClCHO$ . (148°). Formed, together with tri-chloro-butyric aldehyde, by chlorinating aldehyde containing alcohol (Pinner, *Z.* 179, 31). Formed also by heating the hydrate of chloro-

acetic aldehyde with aldehyde and a drop of fuming HCl at 100° (Lieben, A. Zeisel, M. 4, 531). Liquid. Combines with chlorine forming tri-chloro-butyric aldehyde. Br gives chloro-di-bromo- and chloro-tri-bromo-butyric aldehydes (Pinner, D. 8, 1323).

**$\alpha$ -Di-chloro-butyric aldehyde**  
 $\text{CH}_2\text{Cl.CH}_2\text{CHCl.OH.O}$ . (36°) at 18 mm. Gradually separates as an oil when the hydrate of chloro-acetic aldehyde is heated with a drop of  $\text{H}_2\text{SO}_4$  at 100° (Natterer, M. 4, 539; 5, 567). Oil; solidifies when cooled with solid  $\text{CO}_2$ . Forms a crystalline compound with  $\text{NaHSO}_4$ . Reduces warm ammoniacal  $\text{AgNO}_3$ . Reduced by iron filings and acetic acid to *n*-butyl and butenyl alcohols. Oxidised by  $\text{HNO}_3$  to oxalic and chloro-acetic acids. Br forms  $\alpha$ -di-chloro- $\alpha$ - $\beta$ -di-bromo-butyric aldehyde. HCl gives tri-chloro-butyric aldehyde.  $\text{ZnEt}_2$  followed by dilute  $\text{H}_2\text{SO}_4$  gives di-chloro-hexenyl alcohol  $\text{C}_6\text{H}_{11}\text{Cl}_2\text{O}$  (c. 117°) at 20 mm.

**CHLORO-CROTONYL-UREA**  
 $\text{CH}_2\text{CH}_2\text{CHCl.CO.NH.CO.NH}_2$ . [224°]. The chief product of the reaction of the cyanhydrin of tri-chloro-butyric aldehyde with urea; the yield is about 60 p.c. Rhombic tables. Sol. alcohol. sl. sol. water. On heating it evolves HCl and is converted into di-oxy-ethylidene-metapyrazole  
 $\text{CH}_2\text{CH}_2\text{CH}_2\text{O.N}=\text{C}(\text{OH})$  (Pinner & Lifschütz, B. 20, 2347).

**CHLORO-CROTYL v. CHLORO-BUTENYL**  
**CHLORO- $\nu$ -CUMENE**  $\text{C}_6\text{H}_4(\text{CH}_2)_2\text{Cl}$  [1:3:4:6]. [71°]. White plates. Formed by the action of cuprous chloride upon diazo-pseudo-cumene (Haller, B. 18, 93) or by warming the piperidine of diazo-pseudo-cumene with conc.  $\text{HClAq}$  (Wallach & Hoewler, A. 243, 232).

**$\alpha$ -Chloro-*n*-cumene**  $\text{C}_6\text{H}_4\text{Cl}$  i.e.  $\text{C}_6\text{H}_4\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{Cl}$ . **Chloro-propyl-benzene**. [319°]. From  $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{CH}_2\text{OH}$  and HCl (Errera, G. 16, 810). Oil. Not affected by fused  $\text{ZnCl}_2$  nor by  $\text{AgOAc}$ . Alcoholic KOH gives  $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{OEt}$  (220°).

**$\alpha$ -Chloro-*n*-cumene**  $\text{C}_6\text{H}_4\text{CH}_2\text{CHClCH}_2$ . (c. 206°). From  $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{CH(OH)CH}_3$  and HCl (E.). Formed also by chlorination of *n*-propyl-benzene (Errera, G. 14, 506). Partially decomposed by distillation into HCl and allyl-benzene. Alcoholic KOH also forms allyl-benzene, as does  $\text{ZnCl}_2$ , likewise.

**$\beta$ -Chloro-*n*-cumene**  $\text{C}_6\text{H}_4\text{CHClCH}_2\text{CH}_2$ . (c. 203°). From the corresponding phenyl-propyl alcohol and HCl (E.). Partially resolved by distillation, even *in vacuo*, into HCl and allyl-benzene.  $\text{AgOAc}$  forms  $\text{C}_6\text{H}_5\text{CH(OAc)CH}_2\text{CH}_2$  (227°).

**CHLORO-CUMINIC ACID**  $\text{C}_6\text{H}_4\text{ClO}_2$  i.e.  $\text{C}_6\text{H}_4\text{CH}_2\text{CHClCO}_2\text{H}$  [4:3:1]. [238°]. Formed by oxidation by  $\text{HNO}_3$  of the chloro-cumene from thymol and  $\text{PCl}_5$  (Gerichten, B. 11, 865; Fileti & Crosa, G. 16, 288). Long needles (from dilute alcohol). Reduced to cuminic acid by sodium-amalgam.— $\text{BaA}$ ; 8aq; pearly plates.

**CHLORO-CUMOQUINOLINE v. CHLORO-ISO-PROPYL-QUINOLINE**

**CHLORO-CYANAMIDE v. AMMELINE**  
**CHLORO-CYANO-BENZENE v. Nitrile of CHLORO-BENZOIC ACID**

**CHLORO-DI-CYANO-NITRO-METHANE**  
 $\text{CCl}_2\text{C}_2(\text{NO}_2)_2$ . Formed by warming chloropierin

with alcoholic KCy (Basset, C. J. 19, 852). Silver nitrate solution gives an orange pp. of  $(\text{AgNO}_3)_2\text{SCl}_2\text{C}_2(\text{NO}_2)_2$ .

**CHLORO-CYMENE**  $\text{C}_6\text{H}_4\text{Cl}$  i.e.  $\text{C}_6\text{H}_4\text{MePrCl}$  [1:4:2]. (210°). S.G. 1.014. From carvacrol and  $\text{PCl}_5$  (Kekulé & Fleischer, B. 6, 1090). Formed also by chlorination of cymene (from camphor) in presence of iodine (v. Gerichten, B. 10, 1249). Oxidised by dilute  $\text{HNO}_3$  to chloro-toluic acid [196°].

**Chloro-cymene**  $\text{C}_6\text{H}_4\text{MePrCl}$  [1:4:3]. (218°). From thymol (4 mols.) and  $\text{PCl}_5$  (1 mol.); the yield being 85 p.c. (Carstam, J. pr. [2] 3, 64; v. Gerichten, B. 10, 1250; 11, 865; Fileti & Crosa, G. 16, 287). Not affected by sodium amalgam (F. a. C.). Oxidation gives chloro-cuminic [117°], chloro-toluic [149°], and chloro-terephthalic, acids.

**$\alpha$ -Chloro-cymene**  $\text{C}_6\text{H}_4\text{Pr(CH}_2\text{Cl)}$  [1:4]. **Cumyl chloride**. (c. 227°). Formed by passing chlorine into boiling cymene (Errera, G. 14, 277). Decomposed by long boiling with formation of  $\text{C}_6\text{H}_5$ . Alcoholic KOH gives  $\text{C}_6\text{H}_5\text{OEt}$ . Sodium amalgam reduces it to cymene. Boiling aqueous  $\text{Pb}(\text{NO}_3)_2$  gives cuminic aldehyde.

**Exo-chloro-cymene**  $\text{C}_6\text{H}_4(\text{C}_6\text{H}_4\text{Cl})\text{Me}$  [1:4]. Two compounds of this nature are formed, together with the preceding body, on passing chlorine into boiling cymene (derived from camphor). One of them is not attacked by alcoholic KOH, while the other is converted into allyl-toluene  $\text{C}_6\text{H}_4(\text{C}_6\text{H}_5)\text{Me}$  (Errera, G. 14, 293).

**$\alpha$ -Chloro-*p*-isocymene**  $\text{C}_6\text{H}_4\text{Pr(CH}_2\text{Cl)}$  [1:4]. **Cumyl chloride**. (c. 230°). Formed, together with cumyl carbamate, by passing cyanogen chloride into cumyl alcohol  $\text{C}_6\text{H}_4\text{Pr.CH}_2\text{OH}$  (Spica, G. 5, 394). Formed also by the action of HCl on cumyl alcohol (Paterno & Spica, G. 9, 397; B. 12, 2366).

**$\alpha,\omega$ -Di-chloro-cymene**  $\text{C}_6\text{H}_4(\text{C}_6\text{H}_4)(\text{CH}_2\text{Cl})_2$ . **Cumylidene chloride**. (c. 258°). From cuminic aldehyde and  $\text{PCl}_5$  (Cahours, A. 70, 44; Suppl. 2, 311; Sieveking, A. 106, 259). Reconverted by alcoholic KOH or by heating with water at 150° into cuminic aldehyde.

**Tetra-chloro-*m*-isocymene**  $\text{C}_6\text{Cl}_4\text{PrMe}$  [1:3]. [159°]. Formed by passing chlorine into a cold saturated solution of tri-chloro-isocymene sulphonic acid at 40° (Kelbe, B. 16, 617). Needles (from alcohol); may be sublimed. Not oxidised by  $\text{HNO}_3$  or chromic mixture.

**TRI-CHLORO-*m*-ISOCYMENE SULPHONIC ACID**  $\text{C}_6\text{Cl}_3\text{PrMe(SO}_3\text{H)}$ . From *m*-isocymene sulphonic acid by passing Cl into its aqueous solution at 40° (Kelbe, B. 16, 618).— $\text{NaA}$ : laminae.

**CHLORO-DECANE v. DECYL CHLORIDE**  
**CHLORO-DECYLENE**  $\text{C}_{10}\text{H}_{17}\text{Cl}$  (206° cor.). From Cl and boiling decanaphthalene (Markownikoff & Ogloblin, J. R. 15, 833). Alcoholic KOH gives a mixture of decenes (165°–165°).

**TETRA-CHLORO-DURENE**  $\text{C}_6\text{H}_2(\text{CH}_2\text{Cl})_4$  [1:2:4:5]. [144°]. S.G. 1.479. Formed by heating durene with excess of  $\text{PCl}_5$  at 190° for 5 hours (Colson & Gautier, C. R. 103, 1075; B. [2] 46, 198).

**DI-CHLORO-EOSIN v. DI-CHLORO-TETRA-BROMO-FLUORESCIN**

**CHLORO-ETHANE v. ETHYL CHLORIDE**  
**Di-chloro-ethane v. ETHYLENE CHLORIDE and ETHYLIDENE CHLORIDE**

Tri-chloro-ethane  $\text{CH}_3\text{Cl.CHCl}_2$ . *Chloro-ethyl-ene chloride*. (114°) (Schiff, *A.* 220, 97); (115°) (Perkin, *C.* J. 46, 531). V.D. 4.66 (for 4.60). S.G.  $\frac{4}{7}$  1.4577;  $\frac{15}{16}$  1.4563;  $\frac{25}{30}$  1.4430. M.M. 6.798 at 16.7°. C.E. (from 9° to 118°) 00121. H.F.p. 83980 (Th.). H.F.v. 82820. S.V. 102-77.

**Formation.**—1. From chloro-ethylene (vinyl chloride) and  $\text{SbCl}_3$  (Regnault, *A. Ch.* [2] 69, 151; 41, 355).—2. From ethyl chloride and  $\text{Cl}$  (Krämer, *B.* 3, 261).—3. By chlorinating ethylene chloride in presence of  $\text{AlCl}_3$  (Tavildaroff, *B.* 13, 2408).—4. From  $\text{CHCl}_2\text{CH}_2\text{OH}$  and  $\text{PCl}_5$  (de Laere, *C. R.* 104, 1186).

**Reactions.**—1. Aquoguts or alcoholic ammonia gives a theoretical yield of  $\text{C}_2\text{H}_5\text{Cl}$  (37°) (Engel, *C. R.* 104, 1621); alcoholic KOH forms the same body.—2. Sodium forms  $\text{C}_2\text{H}_5$ ,  $\text{C}_2\text{H}_4\text{Cl}_2$ ,  $\text{C}_2\text{H}_3$ , and hydrogen (Brünner & Brandenburg, *B.* 10, 1496; 11, 61).

Tri-chloro-ethane  $\text{CH}_2\text{Cl}_2$ . (76°) (Perkin); (74.5°) (Geuther). V.D. 4.53. S.G.  $\frac{15}{16}$  1.3247;  $\frac{25}{30}$  1.3114. M.M. 6.740 at 17.6° (Perkin); 6.1347 (Pierre, *A.* 80, 127). Formed by chlorinating ethyl chloride (Regnault, *A.* 33, 317; Geuther, *J.* 1870, 435). Converted by  $\text{NaOEt}$  at 100° into  $\text{CH}_3\text{CO}(\text{OEt})$ , acetic acid, and ortho-acetic ether  $\text{CH}_3\text{O}(\text{OEt})$ . Differs from its isomeride in forming, when cooled, with aqueous  $\text{H}_2\text{S}$ , a crystalline compound  $\text{C}_2\text{H}_3\text{Cl}_2\text{HS}$  23aq (Foreaud, *A. Ch.* [5] 28, 25).

*u*-Tetra-chloro-ethane  $\text{CH}_2\text{Cl.CCl}_2$ . (135°) (Regnault); 130° (Pierre, *A.* 80, 130); (130.5° i. V.) (Staedel, *B.* 15, 2563). S.G.  $\frac{4}{7}$  1.6116 (P.);  $\frac{15}{16}$  1.576. Formed by chlorinating ethylene chloride (Laurent, *A.* 22, 293) or  $\text{CHCl}_2\text{CHCl}_2$  (R.). With  $\text{NaOEt}$  it gives  $\text{CHCl}_2\text{CO}(\text{OEt})$  and  $\text{CH}_3\text{CO}(\text{OEt})$ .  $\text{CO}_2\text{Na}$ .  $\text{H}_2\text{S}$  gives  $\text{C}_2\text{H}_3\text{Cl}_2\text{HS}$  23aq.

*s*-Tetra-chloro-ethane  $\text{CHCl}_2\text{CHCl}_2$ . *Acetylene tetrachloride*. (147° cor.). S.G.  $\frac{4}{7}$  1.614 (P. & P.);  $\frac{15}{16}$  1.5897 (Kazannikoff).

**Formation.**—1. By passing acetylene into  $\text{SbCl}_3$ , which slowly absorbs it and deposits  $\text{C}_2\text{H}_3\text{SbCl}_3$ , the mixture of this body with  $\text{SbCl}_3$  is then distilled (Berthelot & Jungfleisch, *C. R.* 79, 542).—2. By passing acetylene into  $\text{PCl}_5$ ; explosion often occurring (Sabanejeff, *A.* 216, 282).—3. By heating ethylene chloride with the calculated quantity of  $\text{PCl}_5$  for ten hours at 190° (Cobison & Gautier, *C. R.* 102, 1075).—4. From di-chloro-acetic aldehyde and  $\text{PCl}_5$  (Paterno & Pisati, *G.* 1, 461; *J.* 1871, 508).

**Properties.**—Not affected by boiling water. Slowly decomposed at 360° giving  $\text{HCl}$  and hexa-chloro-benzene.

Penta-chloro-ethane  $\text{CHCl}_2\text{CCl}_3$ . (158.9°) (Thorpe). S.G.  $\frac{4}{7}$  1.70893. C.E. (0°-10°) 000949; (0°-100°) 000944. S.V. 135.2.

**Formation.**—1. From chlorine and  $\text{EtCl}$  (Regnault, *A.* 33, 321).—2. By chlorinating ethylene chloride (Pierre, *A.* 80, 130).

**Preparation.**— $\text{PCl}_5$  (190 g.) is gradually added to chloral (113 g.), boiled with inverted condenser and distilled. The portion distilling below 170° is washed with water, dried with  $\text{CaCl}_2$ , and rectified. The yield is small (Paterno, *C. R.* 68, 460; Thorpe, *C.* J. 87, 192).

**Properties.**—Liquid, solidifies below -18°. Converted by alcoholic KOH into  $\text{KCl}$  and  $\text{C}_2\text{Cl}_4$ .  $\text{PCl}_5$  at 250° gives  $\text{C}_2\text{Cl}_6$ .

Hexa-chloro-ethane  $\text{CCl}_3\text{CCl}_3$ . [179°] (Geuther & Brookhoff, *J. pr.* [2] 7, 108); [185° cor.] (Hahn, *B.* 11, 1735). (185° cor.) (H.). S.G. 2.0 (Schroder, *B.* 18, 1070). V.D. 8.18 (calc. 8.21).

**Formation.**—1. From  $\text{C}_2\text{Cl}_4$  and  $\text{Cl}_2$  daylight or by heating (Faraday, *Tr.* 1828, 47; Liebig, *A.* 1, 219).—2. The ultimate product of the chlorination of ethyl chloride (Laurent, *A. Ch.* [2] 84, 328) or ethylene chloride (Faraday), and hence formed in the chlorination of most ethyl compounds in sunlight (Regnault, *A. Ch.* [2] 69, 166; 81, 371; Ebelmen & Bouquet, *A. Ch.* [3] 17, 66; Malaguti, *A. Ch.* [3] 16, 6, 14; Geuther & Hofacker, *A.* 108, 51).—3. By passing  $\text{CCl}_4$  through a red-hot tube (Kolbe, *A.* 64, 147) or over finely divided copper at 120° (Radziszewski, *B.* 17, 834) or silver at 180° (Goldschmidt, *B.* 14, 928).—4. From  $\text{AcCl}$  and  $\text{PCl}_5$  at 180° (Hubner & Müller, *Z.* 1870, 328).—5. Ultimate product of the action of  $\text{PCl}_5$  on succinic acid.—6. By heating propane, propyl chloride, or isobutyl chloride and  $\text{ICl}_3$  at 200° (Kraft & Merz, *B.* 8, 1298).—7. From propionic acid and  $\text{ICl}_3$  (Kraft, *B.* 9, 1085).—8. By chlorination of boiling butyric acid in sunshine (Naumann, *A.* 119, 120).—9. Together with  $\text{C}_2\text{Cl}_4$  and  $\text{CCl}_4$  by heating chrysene with  $\text{PCl}_5$  (Ruoff, *B.* 10, 1284).

**Properties.**—Tables (from alcohol-ether); smells like camphor. Trimorphous, crystallising in the cubic, trimetric, and triclinic systems (Lehmann, *J.* 1832, 369; *Z.* K. 6, 580). Insol. water, sol. alcohol and ether. When its vapour is led through a red-hot tube  $\text{C}_2\text{Cl}_4$  is formed.

**Reactions.**—1. Alcoholic potash at 100° converts it into oxalic acid (Berthelot, *A.* 109, 119). Solid potash at 200° does the same (Geuther, *A.* 111, 174).—2. Boiling with  $\text{NaOEt}$  under pressure gives  $\text{C}_2\text{Cl}_4$ ,  $\text{CCl}_3\text{CO}(\text{OEt})$ ,  $\text{CHCl}_2\text{CO}(\text{OEt})$ , and  $\text{CH}_3\text{CO}(\text{OEt})$ .  $\text{CO}_2\text{Na}$  (Geuther & Brookhoff). Zinc and dilute  $\text{H}_2\text{SO}_4$  do the same.—3. Finely divided silver at 280° also gives  $\text{C}_2\text{Cl}_4$ .—4.  $\text{SO}_2$  at 150° forms  $\text{CCl}_3\text{COCl}$  and  $\text{CCl}_2\text{COCl}$  (Pudhomme, *A.* 156, 312; Armstrong, *Pr.* 18, 502).—5.  $\text{AlI}_3$  forms  $\text{C}_2\text{Cl}_6$ ,  $\text{Al}_2\text{Cl}_6$ , and iodine (Gustavson, *B.* 9, 1607).

#### CHLORO-ETHANE TRI-CARBOXYLIC ACID.

*Ethyl ether*  $(\text{CO}_2\text{Et})_3\text{CCl.CH}(\text{CO}_2\text{Et})$  (205°-215°) at 160 mm. From ethane tri-carboxylic ether and chlorine (Bischoff, *A.* 214, 40).

**Reactions.**—1. Boiling aqueous  $\text{HCl}$  forms fumaric acid.—2. KOH and dilute alcohol form malic acid.—3. KOH and 97 p.c. alcohol appear to form  $(\text{CO}_2\text{Et})_3\text{C}(\text{OEt})\text{CH}_2\text{CO}_2\text{Et}$ .

#### *a*-CHLORO-ETHANE SULPHONIC ACID

$\text{CH}_3\text{CHCl.SO}_3\text{H}$ . Its sodium salt  $\text{A}^{\text{Na}}$  is formed by heating ethylene chloride with solution of  $\text{Na}_2\text{SO}_3$  at 140°. This salt forms plates, sol. alcohol (Bunte, *A.* 190, 317).

#### *β*-Chloro-ethane sulphonic acid.

$\text{CH}_2\text{Cl.CH}_2\text{SO}_3\text{H}$ .

**Formation.**—1. By the action of fuming  $\text{HNO}_3$  on  $\text{CH}_3\text{Cl.CH}_2\text{SO}_3\text{Na}$  (Jaffé, *J. pr.* [2] 20, 353).—2. By boiling its chloride with water (Dittrich, *J. pr.* [2] 18, 67; Kolbe, *A.* 122, 38).—3. From  $(\text{CH}_2\text{Cl.CH}_2)_2\text{S}_2$  and  $\text{HNO}_3$  (Spring & Lécronier, *Bl.* [2] 48, 629).

**Properties.**—Very deliquescent needles. Not decomposed by boiling water. Heated with ammonia in sealed tubes at 100° forms taurine,  $\text{CH}_3(\text{NH}_2)\text{CH}_2\text{SO}_3\text{H}$ .

**Salts.**—(B. Hubner, *A.* 223, 218; Jaimes,

*J. pr.* [2] 26, 382; *C. J.* 43, 41).— $\text{NH}_4\text{A}'$ — $\text{NaA}'$  aq.  $\text{KA}'$ : needles, insol. alcohol.— $\text{BaA}'$ , aq (H).— $\text{BaA}'$ , 2aq: needles (J).— $\text{PbA}'$ , 2aq.— $\text{CuA}'$ , 3aq (H).— $\text{CuA}'$ , 4aq: trichloride tablets (J).— $\text{ZnA}'$ , 4aq (H).— $\text{ZnA}'$ , 5aq: plates (J).— $\text{MgA}'$ , 4aq.— $\text{SrA}'$ , 2aq: needles.— $\text{MnA}'$ , 4aq.— $\text{FeA}'$ , 4aq.— $\text{NMeH}_2\text{A}'$ : plates (from alcohol).

**Chloride.**— $\text{CH}_3\text{Cl.CH}_2\text{SO}_3\text{Cl}$  (200°–205°). From potassium isethionate and  $\text{PCl}_5$  (Kolbe, *A.* 122, 38). Also from  $\text{SO}_2\text{Cl.CH}_2\text{CH}_2\text{SO}_2\text{Cl}$  and  $\text{PCl}_5$  (Königs, *B.* 7, 1163). It is one of the products of the action of  $\text{SO}_2$  on ethyl chloride (Purgold, *B.* 6, 502). Oil, smelling like mustard. Does not give an amide with ammonia, or an ether when heated with alcohol.  $\text{PCl}_5$  at 200° gives ethylene chloride.

**Di-chloro-ethane sulphonic acid**

$\text{C}_2\text{H}_4\text{Cl}_2(\text{SO}_3\text{H})$ . From ethane sulphonic acid and  $\text{ICl}_3$  (Spring, *A.* 15, 446). Converted by baryta into chloro-isethionio acid  $\text{C}_2\text{H}_4\text{Cl}(\text{OH})(\text{SO}_3\text{H})$ . Ammonia at 100° gives chlorinated taurine.

**CHLORO-ETHYL-TRICARBOXYLIC ACID**  
v. **CHLORO-ETHANE-TRICARBOXYLIC ACID.**

**CHLORO-ETHER** v. **CHLORO-ETHYL OXIDE.**

**CHLORO-ETHYLIC ACID**  $\text{C}_2\text{H}_4\text{ClO}_2$ . A brown amorphous body formed by adding sodium to chloroform containing alcohol (Hardy, *A. Ch.* [8] 65, 340).

**CHLORO-ETHYL-ACETAMIDE** v. **CHLORO-ETHYLAMINE.**

**CHLORO-ETHYL ACETATE**  $\text{CH}_3\text{CHCl.OAc}$  v. **ALDEHYDES.**

**CHLORO-ETHYL ACETATE**  $\text{CH}_3\text{Cl.CH}_2\text{OAc}$  v. **CHLORO-ETHYL ALCOHOL.**

Other Chloro-ethyl acetates v. Acetyl derivatives of the corresponding CHLORO-ETHYL ALCOHOLS.

**CHLORO-ETHYL-ACETO-ACETIC ETHER**  $\text{C}_2\text{H}_3\text{ClO}_4$ , i.e.  $\text{CH}_2\text{Cl.CO.CHEt.CO}_2\text{Et}$  (192°–5° cor.). S.G. 1.052. A product of action of  $\text{PCl}_5$  on ethyl-aceto-acetic ether (Isbert, *A.* 234, 187; cf. Conrad, *A.* 186, 241). Oil, smelling of peppermint. Sol. alcohol or ether. With dilute  $\text{HCl}$  at 180° it gives mono-chlorinated methyl propyl ketone. With  $\text{NaOEt}$  (1 mol.) in alcohol, it gives rise to ethoxy-ethyl-aceto-acetic ether  $\text{CH}_3(\text{OEt}).\text{CO.CHEt.CO}_2\text{Et}$  (210° cor.). S.G. 1.057. Alcoholic  $\text{KOH}$  at 120° converts it into  $\text{EtO.CH}_2\text{CO.CH}_2\text{Et}$ .

**Di-chloro-ethyl-aceto-acetic ether**  $\text{C}_2\text{H}_2\text{Cl}_2\text{O}_4$  (220°–225°). S.G. 1.183. Formed at the same time as the preceding.

**Chloro-di-ethyl-aceto-acetic ether**  $\text{CH}_3\text{Cl.CO.OEt.CO}_2\text{Et}$ . S.G. 1.063.  $\text{PCl}_5$  has no action on di-ethyl-aceto-acetic ether, even at 100°, but at a higher temperature  $\text{HCl}$ ,  $\text{EtCl}$ , ethyl-chloro-acetate (chloro-hexenoic) ether, di-ethyl-chloro-aceto-acetic ether, and di-ethyl-di-chloro-aceto-acetic ethers are formed. The product is freed from  $\text{PCl}_5$  by distillation, is then poured into water and distilled with steam (James, *C. J.* 40, 50; *A.* 231, 235). Di-ethyl-chloro-aceto-acetic ether is a liquid, which is converted by treatment with sodium methylate  $\text{MeONa}$  into  $\text{CH}_3(\text{OMe}).\text{CO.CO}_2\text{Et.CO}_2\text{Et}$  and  $\text{CH}_3(\text{OMe}).\text{CO.CHMeEt}$  (181°). S.G. 1.055.

**Di-chloro-diethyl-aceto-acetic ether**  $\text{CHCl}_2\text{CO.CO}_2\text{Et.CO}_2\text{Et}$ . S.G. 1.155. One of the products of the action of  $\text{PCl}_5$  on di-ethyl-aceto-acetic ether. Oil, with pleasant smell,

Miscible with alcohol and with ether. Converted by  $\text{NaOMe}$  into  $\text{CH}(\text{OMe}).\text{CO.CO}_2\text{Et.CO}_2\text{Et}$  (195°) and  $\text{CH}(\text{OMe}).\text{CO.CHEt.CO}_2\text{Et}$  (134°). S.G. 1.086 (James, *C. J.* 43, 57).

**CHLORO-ETHYL ALCOHOL**  $\text{CH}_3\text{CHCl.OH}$ . **Ethylidene chlorhydrin.** (25°) at 40mm. An unstable body formed by combination of aldehyde with  $\text{HCl}$  in the cold. It changes spontaneously into 'ethylidene oxy-chloride' or di-chloro-di-ethyl oxide (Hanriot, *A. Ch.* [5] 25, 219), v. **ALDEHYDES**, vol. i. p. 104.

**Acetyl derivative**  $\text{CH}_3\text{CHCl.OAc}$  (121°–5° cor.). Formed by combination of aldehyde with acetyl chloride; v. **ALDEHYDES**, vol. i. p. 105, where other alkyl derivatives are described.

**Methyl derivative**  $\text{CH}_3\text{CHCl.OMe}$  (c. 74°). S.G. 1.096. Formed by passing  $\text{HCl}$  into a well-cooled mixture of aldehyde (1 vol.) and methyl alcohol (1½ vols.) (Rübencamp, *A.* 225, 269).

**Ethyl derivative**  $\text{CH}_3\text{CHCl.OEt}$  v. **CHLORO-DI-ETHYL OXIDE.**

**Chloro-ethyl alcohol**  $\text{C}_2\text{H}_4\text{ClO}$  i.e.  $\text{CH}_2\text{Cl.CH}_2\text{OH}$ . **Glycol chlorhydrin.** Mol. w. 80½ (128°–131°). S.G. 1.223.

**Formation.**—1. By repeatedly saturating glycol with  $\text{HCl}$  and distilling the product (Wurtz, *A.* 110, 125; cf. Schorlemmer, *C. J.* 39, 143). Besides the pure product (128°) a fraction boiling at 106° is obtained; this fraction may be represented as  $(\text{C}_2\text{H}_4\text{ClO})_n\text{HCl}$  8aq, and has S.G. 1.1926; by means of  $\text{KOH}$  (1 mol.) it may be decomposed with liberation of the pure chlorhydrin (Bouchardat, *C. R.* 100, 452).—2. By heating glycol with  $\text{S}_2\text{Cl}_2$  at 100° and extracting the product with moist ether (Carius, *A.* 124, 257); the yield is over 50 p.c. of the theoretical.—3. From ethylene and  $\text{ClOH}$  (Carius, *A.* 126, 197; cf. Butlerow, *A.* 144, 40).—4. From ethylene oxide and  $\text{HCl}$ ; the union is attended with disengagement of heat:  $(\text{C}_2\text{H}_4\text{O.HCl}) = 36,000$  (Berthelot, *C. R.* 93, 185).

**Properties.**—Liquid, miscible with water. A mixture of glycol chlorhydrin (1 mol.) with water (4 mols.) solidifies at  $-17^\circ$ .

**Reactions.**—1. **Oxidised** by chromic mixture to chloro-acetic acid (Kriwaxin, *Z.* 1871, 265).—2. Reduced by sodium amalgam and water to alcohol (Lourengo, *A.* 120, 92).—3. Converted by potash into ethylene oxide.—4. With  $\text{COCl}_2$  in the cold, reacts thus:  $\text{CH}_2\text{Cl.CH}_2\text{OH} + \text{COCl}_2 = \text{HCl} + \text{CH}_2\text{Cl.CH}_2\text{O.COCl}$ , forming the chloro-ethylic ether of chloro-formic acid.—5. Heated with  $\text{K}_2\text{SO}_4$  and water at 180° it forms isethionio acid  $\text{CH}_2\text{OH.CH}_2\text{SO}_3\text{H}$ .—6. Ammonia forms oxyethylamine  $\text{CH}_2\text{OH.CH}_2\text{NH}_2$  together with  $\text{CH}_2\text{OH.CH}_2\text{O.CH}_2\text{CH}_2\text{NH}_2$  (Wurtz, *A.* 114, 51; 121, 226).—7. **Trimethylamine** in aqueous solution forms neurine (Wurtz, *A. Suppl.* 6, 116, 497).—8. **Dimethylamine** gives di-methyl-oxyethylamine  $\text{CH}_2\text{OH.CH}_2\text{NMe}_2$  (Ladenburg, *B.* 14, 240a), and  $\text{CH}_2\text{OH.CH}_2\text{O.CH}_2\text{CH}_2\text{NMe}_2$  (Morley, *C. J.* 37, 234).

**Nitroxyl derivatives**  $\text{CH}_2\text{Cl.CH}_2\text{O.NO}$ . **Chloro-ethyl nitrate.** (150°). S.G. 1.378. From  $\text{CH}_2\text{Cl.CH}_2\text{OH}$ , nitric acid, and  $\text{H}_2\text{SO}_4$ , or from  $\text{CH}_2\text{Cl.CH}_2\text{Br}$  and alcoholic  $\text{AgNO}_3$  (*A. Ch.* [4] 27, 257; Henry, *C. R.* 96, 1062). Oil.

**Acetyl derivatives**  $\text{CH}_2\text{Cl.CH}_2\text{OAc}$ . **Glycol chloracetin.** (145°). S.G. 1.1788. **Formation.**—

1. From glycol,  $\text{HOAc}$ , and gaseous  $\text{HCl}$  at 100°

(Simpson, *A.* 112, 147).—2. From  $\text{CH}_3\text{OH} \cdot \text{CH}_3\text{OAc}$  and  $\text{HCl}$  (Simpson, *A.* 113, 116).—3. From glycol and  $\text{AcCl}$  in the cold (Lourenço, *A. Ch.* [3] 67, 260; 114, 128).—4. From chloro-ethyl alcohol  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$  and  $\text{AcCl}$  (Henry, *B.* 7, 70; Delacere, *Bl.* [2] 48, 707), or  $\text{Ac}_2\text{O}$  at  $110^\circ$  (Ladenburg & Demola, *B.* 6, 1024). *Properties*.—Liquid; converted by aqueous potash into ethylene oxide.

**Chloro-acetyl derivative**  
 $\text{CH}_3\text{CH}_2\text{CH}_2\text{O} \cdot \text{CO} \cdot \text{CH}_2\text{Cl}$ . (198°). From chloro-ethyl alcohol and chloro-acetyl chloride (Delacere, *Bl.* [2] 48, 708), or from ethylene and  $\text{Cl}_2\text{O}$  (Mulder & Bremer, *B.* 11, 1958).

**Di-chloro-acetyl derivative**  
 $\text{CH}_3\text{CH}_2\text{CH}_2\text{O} \cdot \text{CO} \cdot \text{CHCl}_2$ . (211°). S.G. 1.200 (D.).

**Tri-chloro-acetyl derivative**  
 $\text{CH}_3\text{CH}_2\text{CH}_2\text{O} \cdot \text{CO} \cdot \text{CCl}_3$ . (217°). S.G. 1.251 (D.).

**Butyryl derivative**  $\text{CH}_3\text{CH}_2\text{CH}_2\text{O} \cdot \text{CO} \cdot \text{Pr}$ . (190°). S.G. 1.0854. From glycol, butyric acid, and gaseous  $\text{HCl}$  (Simpson, *A.* 113, 119).

**Benzoyl derivative**  $\text{CH}_3\text{CH}_2\text{CH}_2\text{O} \cdot \text{C}_6\text{H}_5$ . (260°–270°). From glycol, benzoic acid, and  $\text{HCl}$  at  $100^\circ$  (S.).

**Di-chloro-ethyl-alcohol**  $\text{CH}_3\text{CHCl} \cdot \text{CH}_2\text{OH}$ . **Acetyl derivative**  $\text{CH}_3\text{CHCl} \cdot \text{CH}_2\text{OAc}$ . (a. 163°). From acetyl-chloride and the hydrate of chloro-acetic aldehyde (Natterer, *M.* 3, 453). Oil. An isomeride (147°) is formed by treating  $\text{CCl}_3\text{CHClOAc}$  with  $\text{Zn}$  and  $\text{HOAc}$  (Curie & Milliet, *B.* 9, 1611).

**Di-chloro-ethyl alcohol**  $\text{CHCl}_2\text{CH}_2\text{OH}$ . (146° i.v.). S.G. 1.145. V.D. 3.93 (calc. 3.97) (Delacere, *C. R.* 104, 1184). From di-chloro-acetic aldehyde and  $\text{ZnEt}_2$ , the product being decomposed by water. Liquid, sl. sol. water, sol. alcohol and ether. Reduces ammoniacal  $\text{AgNO}_3$ . Does not dissolve  $\text{CaCl}_2$ . Fuming  $\text{HNO}_3$  gives di-chloro-acetic acid. Converted by  $\text{PCl}_5$  into  $\text{CHCl}_2\text{CH}_2\text{Cl}$  (115°), and by  $\text{PBr}_3$  into  $\text{CHCl}_2\text{CH}_2\text{Br}$  (138°).

**Nitroxyl derivative**  $\text{CHCl}_2\text{CH}_2\text{NO}$ . **Di-chloro-ethyl nitrate**. (156° i.v.). V.D. 5.56 (calc. 5.53) (De Lacere, *C. R.* 104, 1186). From  $\text{CHCl}_2\text{CH}_2\text{OH}$  by  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ .

**Acetyl derivative**  $\text{CHCl}_2\text{CH}_2\text{OAc}$ . **Di-chloro-ethyl acetate**. (167° i.v.). V.D. 5.74 (calc. 5.42). S.G. 1.104 (Delacere, *C. R.* 104, 1186).

**Chloro-acetyl derivative**  
 $\text{ClCH}_2\text{CH}_2\text{O} \cdot \text{C}(\text{CH}_3)\text{Cl}$ . (215° cor.). S.G. 1.216. Prepared by acting with mono-chloro-acetyl chloride on di-chloro-ethyl alcohol on the water-bath until no more hydric chloride is evolved (Delacere, *Bl.* [2] 48, 708).

**Di-chloro-acetyl derivative**  
 $\text{ClCH}_2\text{CH}_2\text{O} \cdot \text{C}(\text{CH}_3)\text{Cl}_2$ . (223°). S.G. 1.25. Formed by heating di-chloro-ethyl alcohol and di-chloro-acetyl-chloride together on the water-bath (Delacere).

**Tri-chloro-acetyl derivative**  
 $\text{ClCH}_2\text{CH}_2\text{O} \cdot \text{C}(\text{CH}_3)\text{Cl}_3$ . (230°). Formed by the action of tri-chloro-acetyl chloride on di-chloro-ethyl alcohol (Delacere).

**Tri-chloro-ethyl alcohol**  $\text{CCl}_3\text{CH}_2\text{OH}$ . [18°]. (151°). S.G. 1.550.

The zinc salt  $(\text{CCl}_3\text{CH}_2\text{O})_2\text{Zn}$  is formed by the action of  $\text{ZnEt}_2$  on chloral; it is decomposed by water into  $\text{Zn}(\text{OH})_2$  and tri- $\alpha$ -chloro-ethyl alcohol (Garzaroli-Thurnlackh, *A.* 210, 63; Delacere, *Bl.* [3] 48, 785). It is also formed, together with glycuronic acid  $\text{C}_6\text{H}_8\text{O}_7$ , by treating arochloric acid with dilute  $\text{HCl}$  (Kütz, *Z. B.*

20, 161). *Hygroscopic trimetric tables*; sl. sol. water, v. sol. alcohol and ether.  $\text{HNO}_3$  forms tri-chloro-acetic acid. Reduces hot Fehling's solution.

**Acetyl derivative**  $\text{Cl}_3\text{CCH}_2\text{OAc}$ . (170°). S.G. 1.180. Formed by digesting at a gentle heat acetyl chloride and trichloro-ethyl alcohol.

**Chloro-acetyl derivative**  
 $\text{Cl}_3\text{CCH}_2\text{O} \cdot \text{C}(\text{CH}_3)\text{Cl}$ . (220° cor.). S.G. 1.25. From chloro-acetyl-chloride and tri-chloro-ethyl alcohol (Delacere, *Bl.* [2] 48, 710).

**Di-chloro-acetyl derivative**  
 $\text{Cl}_3\text{CCH}_2\text{O} \cdot \text{C}(\text{CH}_3)\text{Cl}_2$ . (231°) at 767 mm. S.G. 1.267. From di-chloro-acetyl chloride and tri-chloro-ethyl alcohol.

**Tri-chloro-acetyl derivative**  
 $\text{Cl}_3\text{CCH}_2\text{O} \cdot \text{C}(\text{CH}_3)\text{Cl}_3$ . (26°). (236°). From tri-chloro-acetyl chloride and tri-chloro-ethyl alcohol.

**Tri-chloro-ethyl alcohol**. **Acetyl derivative**  $\text{CHCl}_2\text{CHCl} \cdot \text{OAc}$ . (185°). From  $\text{AcCl}$  and di-chloro-acetic aldehyde (Delacere, *Bl.* [2] 48, 714).

**DI-CHLORO-ETHYLAMIDO-ACETIC ETHER**  $\text{C}_2\text{H}_4\text{Cl}_2\text{NO}$ . i.e.  $\text{NH} \cdot \text{C}(\text{CH}_3)\text{Cl}_2\text{CO}_2\text{Et}$ . (above  $50^\circ$ ). From  $\text{NH} \cdot \text{Et} \cdot \text{CO}_2\text{CO}_2\text{Et}$  and  $\text{PCl}_5$  (Wallach, *A.* 184, 76). Needles or prisms. Water regenerates  $\text{NH} \cdot \text{Et} \cdot \text{CO}_2\text{CO}_2\text{Et}$ . Ammonia forms ethyl-oxamide.

**p-CHLORO-TETRA-ETHYL-p-DI-AMIDO-TRI-PHENYL-CARBINOL**

$\text{C}_6\text{H}_4\text{Cl}(\text{CH}(\text{OH})(\text{C}_6\text{H}_5)_2)_2$ . [121°]. Large glistening colourless tables. Formed by oxidation of its leuco-base, the condensation-product of diethylaniline and *p*-chlorobenzaldehyde. Its zinc double chloride is a bluish-green dyestuff (Kaeswurm, *B.* 19, 745).

**TRI-CHLORO-p-ETHYL-AMIDO-PHENYL-ETHYL ALCOHOL**  $\text{CCl}_3\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{NH} \cdot \text{Et}$ . [98°]. From chloral hydrate and ethyl-aniline. Crystals (from alcohol).  $\alpha$ - $\text{B}^*\text{HCl}$ .

**Nitrosamine**  $\text{CCl}_3\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{NH} \cdot \text{NO}$  [138°]. Crystals (Boessneck, *B.* 21, 733).

**Tri-chloro- $\alpha$ -ethyl-amido-phenyl ethyl alcohol**  $\text{CCl}_3\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{NH} \cdot \text{Et}$ . Yellow oil. Formed by adding 10 grms. of  $\text{ZnCl}_2$  to a cold mixture of 60 grms. of diethylaniline and 20 grms. of chloral hydrate, and allowing to stand for 2 days at  $40^\circ$ . It is decomposed by alkalis into chloroform and *p*-di-ethyl-amido-benzaldehyde.  $\alpha$ - $\text{B}^*\text{HCl}$ : crystalline solid (Boessneck, *B.* 19, 367).

**p-CHLORO-TETRA-ETHYL-p-DI-AMIDO-TRI-PHENYL-METHANE**

$\text{C}_6\text{H}_4\text{Cl}(\text{CH}(\text{C}_6\text{H}_5)_2)_2$ . [110°]. Obtained by heating together di-ethyl-aniline, *p*-chloro-benzaldehyde, and  $\text{ZnCl}_2$  (Kaeswurm, *B.* 19, 744). Small colourless needles. Sol. benzene, alcohol, and ether, insol. water. On oxidation it gives a bluish-green dyestuff.

**CHLORO-ETHYL-AMINE** *see Ethyl-chloro-amine*, described under **ETHYL-AMINE**.

**$\beta$ -Chloro-ethyl-amine**  $\text{ClCH}_2\text{CH}_2\text{NH}_2$ . From vinylamine and conc.  $\text{HCl}$  aq. Formed also by heating oxyethylphthalimide with conc.  $\text{HCl}$  to  $200^\circ$  (Gabriel, *B.* 21, 573, 1049).—**Salts**.— $\text{B}^*\text{HCl}$ . V. s. sol. alcohol, ether, and water.—**Picrate**.— $\text{B}^*\text{C}_6\text{H}_5\text{N}_3\text{O}_4$  aq. Yellow needles. [148° anhydrous].  $\text{B}^*\text{H} \cdot \text{PicCl}$ . Orange plates. V. sol. water, sl. sol. alcohol.

**CHLORO-ETHYL-ANILINE**  $C_6H_4ON$  *i.e.*  $H_2N.H_2CH_2CH_2Cl$ . Formed by the action of fuming HCl at  $170^\circ$  on the compound  $C_6H_5NO_2$  derived from  $\alpha$ -phenyl-carbamic acid (*q. v.*).—HCl. [188°] (Nemirovsky, *J. pr.* [3] 81, 178).

*p*-Chloro-ethyl-aniline [4:1]  $C_6H_4Cl.NH_2$ . From *p*-chloro-aniline and EtBr. Liquid (Hofmann, *A.* 74, 143).

*p*-Chloro-di-ethyl-aniline [4:1]  $C_6H_4Cl.NEt_2$ . From the preceding and HBr (H.). Liquid.— $H_2PtCl_6$ .

#### *Esso*-CHLORO-ETHYL-BENZENES

$(H_2Cl)(C_2H_5)_2$ . The three *esso*-chloro-ethyl-benzenes are obtained simultaneously by the action of  $C_2H_5$  upon  $C_2H_5Cl$  (500 g.), in presence of  $AlCl_3$  (100 gr.). The mixture is an oily liquid  $b.p. 180^\circ$ . S.G. 1.068. V.D. 4.77. Very volatile, and of agreeable odour. Sol. ligroin (1 vol.),  $CS_2$ ,  $CHCl_3$ , and ether. Sol.  $C_2H_5$  (2 vols.) and alcohol (3 vols.). The proportion of the three isomers is roughly *o*:*m*:*p* = 7:10:3. On oxidation it gives a mixture of the three chloro-*ortho* acids. Heated with sulphuric acid it gives sulphonic acids (Istrati, *A. Ch.* [6] 6, 402; *ib.* [2] 42, 114).

*o*-Chloro-ethyl-benzene  $CH_2Cl.CH_2.C_6H_4$  (?). *o*. 202°. Formed by chlorinating boiling ethylbenzene (Fittig & Kiesow, *A.* 156, 246; cf. Schramm, *M.* 8, 105). Split up by boiling into *tol* and styrene. Converted by alcoholic KOH into the nitrile of  $\beta$ -phenyl-propionic acid (?).

*a*-Chloro-ethyl-benzene  $CH_3.CHCl.C_6H_5$ . 194°. Formed by the action of chlorine on ethylbenzene in sunlight, and also on boiling ethylbenzene (Schramm, *M.* 8, 101). Formed also by passing HCl into cold *o*-phenyl-ethyl alcohol  $C_6H_4.CH(OH).CH_3$  (Engler & Bethge, *B.* 1, 1127). With benzene and  $AlCl_3$  it gives *s*-dihethyl-ethane (Anschütz, *A.* 235, 829).

Chloro-di-ethyl-benzenes  $C_2H_5O(C_2H_5)_2$ . A mixture of chloro-di-ethyl-benzenes is formed by treating  $C_2H_5Cl$  with  $C_2H_5$  in presence of  $AlCl_3$ . It is a mobile liquid, with agreeable odour. (*c.* 218°). S.G. 1.036. V.D. 5.65. Sol. ligroin (in all proportions),  $CS_2$ , ether, and  $CHCl_3$ . Sol. benzene (3 vols.), alcohol (7 vols.). On oxidation, it gives rise to two chloro-phthalic acids, and chloro-ethylphenyl methyl ketone  $C_6H_4.C_2H_5.Cl.CO.CH_3$  (Istrati).

Chloro-tri-ethyl-benzenes  $C_3H_7Cl(C_2H_5)_2$ . A mixture of these substances is obtained by continuing the passage of ethylene into chlorobenzene in presence of  $AlCl_3$ . Mobile liquid. 248°. V.D. 6.87. Sol. (in all proportions) ether, petroleum ether,  $CS_2$ , and  $CHCl_3$ . Sol. benzene (3½ vols.), and alcohol (30 vols.). On oxidation with permanganate it gives a tri-carboxylic acid, having an insol. Ba salt (Istrati, *A. Ch.* [6] 6, 420).

Chloro-tetra-ethyl-benzenes  $C_4H_9Cl(C_2H_5)_3$ . A mixture of isomerides of this composition is formed by the further action of  $C_2H_5$  upon  $C_2H_5Cl$  in presence of  $AlCl_3$ . Liquid. S.G. 1.022. (*c.* 271). V.D. 7.17. V. sol. ether, ligroin,  $CS_2$ , and  $CHCl_3$ . Sol. benzene (4 vols.) and 90 p.c. alcohol (26 vols.) (Istrati).

Chloro-penta-ethyl-benzene  $C_5H_{11}Cl(C_2H_5)_4$ . Formed by the prolonged action of  $C_2H_5$  upon  $C_2H_5Cl$  in presence of  $AlCl_3$ . The yield is not good. Mobile liquid. S.G. 1.065. (*c.* 292°). V.D. 8.43. V. sol. ether, ligroin,  $CS_2$ , and  $CHCl_3$ .

Sol. benzene (5½ vols.) and 90 p.c. alcohol (32 vols.) (Istrati, *A. Ch.* [6] 6, 420).

Di-chloro-ethyl-benzene  $C_2H_5Cl_2(C_2H_5)_2$  [1:4:2]. S.G. 1.239. (218°). V.D. 6.24. Formed by the action of  $C_2H_5$  upon  $C_2H_5Cl$  [1:4] in presence of  $AlCl_3$ , at  $125^\circ$ – $150^\circ$  (Istrati, *A. Ch.* [6] 6, 478). Liquid. Sol. benzene (3 vols.) and 90 p.c. alcohol (9 vols.). Yields a di-chloro-benzoic acid on oxidation.

*o*-Di-chloro-ethyl-benzene  $C_2H_5CH_2.CCl_2H$ . *Phenyl-di-chloro-ethane*. Formed by the action of  $PCl_5$  on phenyl-acetic aldehyde (Forrer, *B.* 17, 982). Heavy colourless liquid. Volatile with steam. By boiling with water it is converted into *o*-chloro-styrene.

*a*-Di-chloro-di-ethyl-benzene  $C_2H_5.CCl_2.CH_2$ . *Acetophenone chloride*. From acetophenone and  $PCl_5$  in the cold (Friedel, *Bl.* 1, 7; Ladenburg, *A.* 217, 105). Readily splits off HCl.

*o*-Di-chloro-di-ethyl-benzene  $C_2H_5CHCl.CHCl$ . *Styrene dichloride*. From styrene and chlorine (Blyth & Hofmann, *A.* 53, 309). Decomposed on distillation. Alcoholic KOH gives  $C_6H_5CH:CHCl$ .

Di-chloro-di-ethyl-benzene  $C_2H_5Cl_2(C_2H_5)_2$ . A mixture of di-chloro-di-ethyl-benzenes is obtained by treating *p*-di-chlor-benzene with  $C_2H_5$  in presence of  $AlCl_3$ . Liquid. S.G. 1.179. (*c.* 247°). V.D. 7.17. Sol. benzene (4 vols.) and alcohol (16 vols.) (Istrati, *A. Ch.* [6] 6, 482).

Di-chlor-tri-ethyl-benzene  $C_3H_7Cl_2(C_2H_5)_2$  [1:4:3:5:6]. S.G. 1.131. (*c.* 273°). V.D. 8.77 (calc. 7.99). Formed by the action of  $C_2H_5$  upon *p*-di-chlor-benzene in presence of  $AlCl_3$  (Istrati). Liquid. Sol. benzene (5 vols.), alcohol (30 vols.).  $HNO_3$  gives  $C_6(NO_2)Cl_2(C_2H_5)_2$ . (20°). (313°).  $H_2SO_4$  gives  $C_6(SO_3H)Cl_2(C_2H_5)_2$ .

Di-chloro-tetra-ethyl-benzene  $C_4H_9Cl_2(C_2H_5)_3$ . S.G. 1.129. (296°). V.D. 9.26 (calc. 8.96). Prepared by the action of  $C_2H_5$  upon *p*-di-chloro-benzene in presence of  $AlCl_3$ . Liquid. Sol. 90 p.c. alcohol (46 vols.) and benzene (6 vols.) (Istrati, *A. Ch.* [6] 6, 485).

Tri-chloro-ethyl-benzene  $C_2H_5Cl_3(C_2H_5)_2$ . A mixture of these bodies is formed by treating  $C_2H_5Cl$  [1:2:4] with  $C_2H_5$  in presence of  $AlCl_3$  (Istrati, *A. Ch.* [6] 6, 490). Liquid. S.G. 1.389. (244°). V.D. 7.24. Sol. benzene (3½ vols.) and alcohol (17 vols.).

Tri-chloro-di-ethyl-benzene  $C_3H_7Cl_3(C_2H_5)_2$ . A mixture of these bodies is obtained by treating  $C_2H_5Cl$  [1:2:4] with  $C_2H_5$  in presence of  $AlCl_3$ . Liquid, greases paper. S.G. 1.305. (269°). V.D. 8.37. Sol. benzene (5 vols.) and alcohol (26 vols.).

Tri-chloro-tri-ethyl-benzene  $C_4H_9Cl_3(C_2H_5)_3$ . S.G. 1.240. (301°). V.D. 8.42 (calc. 8.19). Prepared by passing  $C_2H_5$  into a mixture of  $AlCl_3$  and  $C_2H_5Cl$  [1:2:4]. Oil. Sol. benzene (5 vols.) and alcohol (41 vols.).

Tetra-chloro-ethyl-benzene  $C_4H_9Cl_4(C_2H_5)_2$ . S.G. 1.543. (*c.* 372°). V.D. 7.99 (calc. 8.47). Formed by treating  $C_2H_5Cl$  [1:3:4:5] with  $C_2H_5$  in presence of  $AlCl_3$ . Yellowish liquid. Sol. benzene (5½ vols.) and 90 p.c. alcohol (16 vols.).  $HNO_3$  gives a nitro-derivative [30°] (Istrati, *A. Ch.* [6] 6, 497).

*Esso*-Tetra-chloro-ethyl-benzene  $CHCl_2.CCl_2.C_2H_5$ . From di-chloro-styrene and  $CHCl_3$  (Dyckerhoff, *B.* 10, 533). Liquid. On distillation it splits up into HCl and  $CCl_2.CCl_2.C_2H_5$ .

Tetra-chloro-di-ethyl-benzene  $C_2Cl_4(C_2H_5)_2$ , [1:3:4:5:2:6]. S.G. 1.431. [45°]. (290°). V.D. 8.44 (calc. 9.07). Formed by treating *u*-tetra-chloro-benzene with ethylene and  $AlCl_3$ . Prisms (from a mixture of alcohol and benzene). Sol. benzene (7 vols.) and 90 p.c. alcohol (40 vols.) (Istrati, *A. Ch.* [6] 6, 500).

Penta-chloro-ethyl-benzene  $C_2Cl_5(C_2H_5)$ . [85°]. (c. 227°). S.G. 1.720. V.D. 9.57 (calc. 9.29). Prepared by submitting  $C_2H_5Cl$ , in presence of  $C_2H_5$ , to the influence of  $AlCl_3$ . The yield is small.  $HCl$  gas facilitates the reaction and gives a better yield. White crystals (from alcohol with benzene). V. sol. ether,  $CHCl_3$ , ligroin and  $CS_2$ . Sol. benzene (5 vols.) and 90 p.c. alcohol (108 vols.). On oxidation with permanganate it gives  $C_2Cl_5CO_2H$ , which immediately loses  $CO_2$  forming  $C_2H_5Cl$  (Istrati, *A. Ch.* [6] 6, 502).

CHLORO-ETHYL-BENZENE SULPHONIC ACID  $C_2H_5Cl(C_2H_5)(SO_3H)$ . Formed by heating the mixture of chloro-ethyl-benzene with  $H_2SO_4$  at 160°. The product appears to consist of several isomerides (Istrati, *A. Ch.* [6] 6, 411).

*Eso*-CHLORO-ETHYL-BENZOIC ACID  $C_2H_5(C_2H_5)ClCO_2H$ . [115°]. Formed by fusing the ketone  $C_2H_5Cl(C_2H_5)CO_2CH_3$  with  $KOH$ . White solid; insol. water; begins to sublime at 100°. —  $BAA'$ : small crystals; insol. cold water (Istrati, *A. Ch.* [6] 6, 424).

CHLORO-ETHYL CARBAMATE  $NH_2CO_2C_2H_5Cl$ . [115°] (G.); [76°] (N.). Formed by the action of chloro-ethyl-alcohol (glycol chlorhydrin) on chloro-formamide (Gattermann, *A.* 244, 41); and of  $ClCH_2CH_2O.COCl$  on ammonia (Nemirowsky, *J. pr.* [2] 31, 174). Colourless, strongly refractive plates. Insol. cold, m. sol. hot water.

TETRA-CHLORO-DI-ETHYL CARBONATE  $(C_2H_5Cl)_2CO_2$ . Obtained by passing chlorine into carbonic ether in diffused daylight, ultimately at 80° (Cahours, *A. Ch.* [3] 9, 201). Heavy oil, decomposed by heat.

Per-chloro-di-ethyl carbonate  $(C_2Cl_5)_2CO_2$ . [86°]. Formed by chlorinating the preceding in direct sunshine (Malaguti, *A. Ch.* [3] 16, 30). Mass of needles. Distils with partial decomposition into  $CO_2$ ,  $C_2Cl_5$ , and  $CCl_3COCl$ . Solution in alcohol converts it into carbonic and tri-chloro-acetic ethers. Aqueous  $KOH$  gives potassium formate, carbonate, and chloride. Gaseous or aqueous ammonia forms tri-chloro-acetamide (Gerhardt, *Traité*, 1, 166) and a substance melting at 37°.

CHLORO-ETHYL-CROTONIC ACID  $C_2H_5ClO_2$ . *Chloro-hexenoic acid*. [49.5°]. (215°). S. 2 at 1°; 33 at 12°. Formed, together with chloro- and di-chloro-ethyl-aceto-acetic ether by the action of  $PCl_5$  upon ethyl-aceto-acetic ether. Needles (from alcohol or ether). Unpleasant, pungent odour (Isberg, *A.* 234, 188; cf. Demarety, *B.* 10, 1177). Not reduced by sodium amalgam. Salts. —  $NaA'$  deliquescent. —  $BAA'$ . —  $CaA'$ . 2 aq. S. 12 at 19°. Prisms. —  $AgA'$ . *Ethyl ether EtA'*. (185°).

CHLORO-ETHYL CYANIDE *o. Nitrile of Chloro-propionic acid*.

CHLORO-ETHYLENE  $C_2H_3Cl$  i.e.  $CH_2:CHCl$ . *Vinyl chloride*. (—16°). V.D. 2.17. H.F.p. —1880 (Th.). H.F.v. —2400. Formed by the action of alcoholic  $KOH$  on ethylene chloride  $CH_2ClCH_2Cl$  (Regnault, *A.* 14, 28), or on ethyl-

idene chloride  $CH_2:CHCl_2$  (Wurtz & Frapoll, *A.* 108, 224). It is a gas which polymerises in sunshine, changing to an amorphous mass, S.G. 1.41, which melts and turns black at 180° (Bauermann, *A.* 168, 817). Ammonia has no action on chloro-ethylene below 100°, but at 160° it forms ethylene diamine  $CH_2NH_2CH_2NH_2$  (118°) (Engel, *B.* [2] 48, 94). Chlorine unites with  $CH_2:CHCl$  in sunshine.

*u*-Di-chloro-ethylene  $CH_2:CCl_2$ . (86°). S.G. 1.250. V.D. 3.32 (calc. 3.36). Formed by the action of alcoholic  $KOH$  on  $CH_2ClCHCl_2$  (Regnault, *J. pr.* 18, 80; Krämer, *B.* 3, 261), on  $CH_2BrCHCl_2$ , or on di-chloro-iodo-ethane (Henry, *C. R.* 97, 1491; 98, 518). Liquid, with allfaceous odour; changes spontaneously into a crystalline isomeride. Chlorine in daylight followed by sunshine gives  $C_2Cl_4$ ; direct sunshine gives  $O$  and  $HCl$ . Does not react with  $KI$ .

*s*-Di-chloro-ethylene  $CHCl:CHCl$ . *Acetylene dichloride*. Mol. w. 97. (56°). Formed by passing acetylene into cool  $SbCl_3$ , the resulting crystalline compound  $C_2H_2SbCl_3$  being decomposed by water (Berthelot & Jungfleisch, *A. Ch.* [4] 26, 472; but cf. Sabanejeff, *A.* 216, 262). From  $CHClBr:CHClBr$  and zinc in alcoholic solution (S.).

Tri-chloro-ethylene  $CHCl:CCl_2$ . (88°). From either tetra-chloro-ethane by treatment with alcoholic  $KOH$  (Berthelot & Jungfleisch, *C. R.* 79, 542; *A. Suppl.* 7, 255). From  $C_2Cl_6$ , zinc, and dilute  $H_2SO_4$  (E. Fischer, *Z.* 1864, 268). Also from chloral and  $P_2S_5$  at 170° (Paternò & Ogliastro, *B.* 7, 81). With alcoholic  $KOH$  it gives  $C_2HCl_3OEt$ . Aqueous or alcoholic  $NH_3$  forms  $C_2H_3Cl_3$  (37°) (Engel, *C. R.* 104, 1621). Sodium forms acetylene, ethylene,  $C_2H_3Cl_3$ , and hydrogen (Brunner & Brandenburg, *B.* 10, 1496; 11, 61).

Tetra-chloro-ethylene  $C_2Cl_4$  i.e.  $CCl_2:CCl_2$ . (121°) (S.); (125°) (L.). S.G. 1.6312 (Schiff, *A.* 220, 97); 1.6190. V.D. 5.82 (calc. 5.75). C.E. (9.4° to 120°) 0.01147,  $\mu_s$  1.513.  $R_{\infty}$  49.66 (Brühl). S.V. 114.18. H.F.p. —1150 (Th.). H.F.v. —1730. Discovered by Faraday (*T.* 1821, 47) by subjecting  $C_2Cl_6$  to a red heat either alone or in presence of  $H$ . Formed also by treating  $C_2Cl_4$  with alcoholic  $KHS$  (Regnault, *A. Ch.* [2] 70, 104; 81, 372), with water and granulated zinc (Geuther, *A.* 107, 212), with alcohol and zinc filings, or with aniline (Bourgoin, *B.* [2] 23, 344). Formed also by the action of  $AlCl_3$  on chloral (Combes, *A. Ch.* [6] 12, 298). Obtained, together with  $CCl_4$ , by heating per-chloro-propane at 300° (Krafft & Merz, *B.* 8, 1300).

Reactions.—1. *Bromine* forms in sunshine crystals of  $C_2Cl_3Br$ .—2. *Dry chlorine* combines in sunshine forming  $C_2Cl_6$ .—3. *Chlorine-water* gives tri-chloro-acetic acid (Kolbe, *A.* 54, 181).—4. *Dry oxygen* has no action even at 120° (Demarety, *B.* 11, 1302).—5. *Potash-fusion* gives potassium oxalate and hydrogen (Geuther, *A.* 111, 174).—6.  $NaOEt$  at 120° gives  $CHCl_2CO(OEt)$ ,  $CHClCO_2Et$ ,  $CH(OEt)CO_2Na$  and  $CCl_3CO(OEt)$  (Geuther, *J.* 1804, 816; *J. pr.* [2] 7, 108).—7.  $SO_2$  at 150° gives  $CCl_3COCl$ .

CHLORO-ETHYLENE OXIDE  $C_2H_3ClO$  (89°–92°). Formed by heating chloro-iodo-ethylene  $CHCl:CHI$  with water (50 vols.) at 150° in

6 days (Sabanejeff, *A.* 216, 268). Liquid. Sl. sol. water.

**CHLORO-ETHYLENE CHLORIDE** *v.* TRI-CHLORO-ETHANE.

**CHLORO-ETHYL ETHER** *v.* CHLORO-DI-ETHYL OXIDE.

**TRI-CHLORO-ETHYLIDENE-ACETIC-ACETIC ETHER** *v.* ACETIC-ACETIC ACID.

**TRI-CHLORO-ETHYLIDENE DIAMINE.**

*Acetyl derivative*  $\text{CCl}_3\text{CH}(\text{NHAc})_2$ . Formed by heating chloral with aceto-nitrile (Hübner, *Z.* 1871, 712; Hepp, *B.* 10, 1651), the equation being:  $\text{CCl}_3\text{CHO} + 2\text{CH}_3\text{CN} + \text{H}_2\text{O} = \text{CCl}_3\text{CH}(\text{NH.CO.CH}_3)_2$ . Needles (from glacial acetic acid). Sol. water and alcohol. Sublimes without melting.

*Benzoyl derivative*  $\text{CCl}_3\text{CH}(\text{NH.Bz})_2$ . [257°]. From chloral, benzonitrile, and conc.  $\text{H}_2\text{SO}_4$ . Needles; *v.* sl. sol. ether.

**CHLORO-ETHYLIDENE-ANILINE**

$\text{C}_6\text{H}_5\text{NCl}$  *i.e.*  $\text{CH}_2\text{Cl.CH.NC}_6\text{H}_5$ . [136°].

*Preparation.*—Di-chloro-di-ethyl oxide  $\text{CH}_3\text{Cl.CHCl.OEt}$  (1 mol.) is warmed with aniline (2 mols.) in the presence of water. A white powder [87°] is formed, which becomes red [136°] when dried.

*Properties.*—Red brown powder. Sol. alcohol; it may be a polymeride of the white compound.

*Reactions.*—1.  $\text{HNO}_3$  produces a yellowish grey amorphous body which gives a blue colour with phenol and conc.  $\text{H}_2\text{SO}_4$ .—2. Warmed with aniline it forms phenylamido-ethylidene aniline  $\text{C}_6\text{H}_5\text{N.CHCl.CH.NHC}_6\text{H}_5$  [104°] which yields indole on heating (Berlinerblau a. Polikiev, *M.* 8, 187-189).

**CHLORO-ETHYLIDENE DI-CARBAMIC ETHER**  $\text{C}_6\text{H}_5\text{ClN.O}$ , *i.e.*  $\text{CH}_2\text{Cl.CH}(\text{NH.CO.OEt})_2$ . [147°]. Formed by the action of chlorine on a strong solution of HCN in alcohol; and also by adding conc. aqueous  $\text{HCl}$  to a solution of carbamic ether in chloro-acetal  $\text{CH}_3\text{Cl.CH}(\text{OEt})_2$  (Bischoff, *B.* 5, 81; 7, (330). Formed also by chlorinating ethylidene di-carbamic ether (Schmid, *J. pr.* [2] 24, 122). Needles (from dilute alcohol). *V.* sol. ether and alcohol.

Di-chloro-ethylidene di-carbamic ether  $\text{CHCl}_2\text{CH}(\text{NH.CO.OEt})_2$ . [122°]. Formed by passing Cl into an alcoholic solution of  $\text{HgCy}_2$  (Stenhouse, *A.* 33, 92; Bischoff, *B.* 5, 82). Also by passing chlorine into carbamic ether at 90° (Schmid, *J. pr.* [2] 24, 120). Long needles; *v.* sol. alcohol and ether.

**TRI-CHLORO-ETHYLIDENE-TRI-CHLORO-LACTATE** *v.* CHLORALDEHYDE.

**CHLORO-ETHYLIDENE GLYCOL**, *derivatives of*, *v.* CHLORO-ALDEHYDE.

**TRI-CHLORO-ETHYLIDENE-MALONIC ACID**,  $\text{CCl}_3\text{CH}(\text{CO}_2\text{H})_2$ .

*Ethylether*  $\text{Et}_2\text{A}$ . (160°-164°) at 23 mm. From chloral, malonic ether and  $\text{Ac}_2\text{O}$  at 160° (O. M. Thompson, *A.* 218, 169).

**TRI-CHLORO-ETHYLIDENE-DI-PHENYLDIAMINE** *v.* TRI-CHLORO-DI-PHENYL-ETHYLIDENE DIAMINE.

**TRI-CHLORO-ETHYLIDENE-QUINALDINE** *v.* (Py. 3). QUINOLYL-ACRYLO-TRI-CHLORIDE.

**CHLORO-ETHYLIDENE-p-TOLUIDINE**  $\text{C}_6\text{H}_4\text{NCl}$  *i.e.*  $\text{CH}_2\text{Cl.CH.N.C}_6\text{H}_4\text{Cl}$ . [58°]. Prepared by decomposing di-chloro-ether  $\text{CH}_2\text{Cl.CHCl.OEt}$  with water, and adding *p*-

toluidine. Sol. alcohol and ether; forms with aniline or toluidine a compound free from chlorine. Heated with aniline it yields indole (Berlinerblau a. Polikiev, *M.* 8, 190, 191).

**DI-CHLORO-ETHYLIDENE-UREA**

$\text{CO}(\text{NH})\text{CH}_2\text{CHCl}_2$ . From di-chloro-acetic aldehyde and urea (Schiff, *A.* 151, 186). Needles.

*Tri-chloro-ethylidene-di-urea*  $\text{C}_6\text{H}_5\text{Cl}_3\text{N}_3\text{O}_3$ , *i.e.*  $\text{CCl}_3\text{CH}(\text{NH.CO.NH})_2$ . Is the chief product of the reaction of chloral-cyanhydrin with urea. White needles. Insol. ordinary solvents (Finner a. Lifschütz, *B.* 20, 2346).

**CHLORO-ETHYL-MALONIC ETHER**

$\text{C}_6\text{H}_5\text{CCl}_2(\text{CO}_2\text{Et})_2$ . (228°). S.G.  $\Delta$  1.11. Liquid. Prepared by passing Cl into ethyl-malonic ether (Courad, *B.* 14, 618). By saponification with baryta-water it gives ethyl-tartronic acid.

**DI-CHLORO-ETHYL MERCAPTAN**

$\text{CH}_2\text{Cl.CH}_2\text{SCH}_3$  (?). S.G.  $\Delta$  1.408. Said to be formed from ethylene and  $\text{SCl}_2$  (Guthrie, *A.* 113, 275). Pungent oil, al. sol. ether.

**CHLORO-DI-ETHYL OXIDE**  $\text{C}_2\text{H}_5\text{ClO}$  *i.e.*  $\text{CH}_3\text{CHCl.OEt}$ . *Aldehyde ethyl-chloride*. Mol. w. 108. (98°).

*Formation.*—1. The first product of the action of chlorine on ether (Lieben, *A.* 111, 121; 146, 180; Abeljanz, *A.* 164, 197; Jacobsen, *B.* 4, 215).—2. By the action of HCl on an alcoholic solution of aldehyde (Wurtz a. Frapelli, *A.* 108, 226; Claus a. Trainer, *B.* 19, 3004).—3. By the action of  $\text{PCl}_5$  (1 mol.) on di-ethyl-acetal (1 mol.) (Bachmann, *A.* 218, 39).—4. By the union of aldehyde with  $\text{EtCl}$ .

*Reactions.*—1.  $\text{NaOEt}$  gives acetal.—2. Conc.  $\text{H}_2\text{SO}_4$  gives  $\text{EtHSO}_4$ , aldehyde and  $\text{HCl}$ .—3. Cold water forms aldehyde, alcohol, and  $\text{HCl}$ . Water at 80° gives aldehyde (Laatsch, *A.* 218, 36). *Alkalis* act in the same way. Cold alcohol has no action, but at 80° aldehyde and  $\text{EtCl}$  are formed.—4. Decomposes on keeping into  $\text{HCl}$  and a liquid boiling at 76°.

*ω-Chloro-di-ethyl oxide*  $\text{CH}_3\text{Cl.CH}_2\text{CH}_2\text{OEt}$ . (108°). S.G.  $\Delta$  1.0572. V.D. 3.73 (calc. 3.74). From iodo-di-ethyl oxide by the action of  $\text{Cl}_2$  of  $\text{SbCl}_5$ , or of  $\text{IOI}$  in presence of water (Henry, *C.R.* 100, 1007). It is not affected by light or by water.

*ωω-Di-chloro-di-ethyl oxide*  $\text{CH}_2\text{Cl.CHCl.OEt}$ . (c. 143°). S.G.  $\Delta$  1.174. V.D. 4.93. Obtained by the action of chlorine on ether below 30° (Lieben, *A.* 111, 121; 123, 130; 133, 287; 141, 236; 146, 180; 150, 87; Abeljanz, *A.* 164, 197; cf. D'Arcet, *A.* 28, 82; Regnault, *A. Ch.* [2] 71, 392; Malaguti, *A. Ch.* [2] 70, 338; [3] 16, 5, 19). Formed also, together with the preceding, by passing  $\text{HCl}$  into a mixture of aldehyde and alcohol (Natterer, *M.* 5, 496) and also from vinyl-ethyl oxide  $\text{CH}_2\text{CH}_2\text{CH}_2\text{OEt}$  and  $\text{Cl}_2$ .

*Reactions.*—1. Water at 120° gives the compound  $\text{CH}_2\text{Cl.CH}(\text{OH})(\text{OEt})$ , together with chloro-acetic aldehyde, glycolic aldehyde, alcohol and  $\text{HCl}$ .—2. Conc.  $\text{H}_2\text{SO}_4$  produces  $\text{EtHSO}_4$ , chloro-acetic aldehyde, and  $\text{HCl}$ .—3. With conc. *potash* it forms chloro-aldehyde alcoholate and its anhydride, and also 'oxychloro-ether',  $\text{CH}_3\text{OH.CH}_2\text{Cl.OEt}$  (151°-155°). This latter body is split up by conc.  $\text{H}_2\text{SO}_4$  into  $\text{HCl}$ , alcohol and glycolic aldehyde (?),  $\text{CH}_3\text{OH.CH}_2\text{O}$ .—4.  $\text{NaOEt}$  gives chloro-acetal  $\text{CH}_2\text{Cl.CH}(\text{OEt})_2$  and  $\text{CH}_3\text{CH}(\text{OEt}).\text{OH}(\text{OEt})$ .—5.  $\text{AgOAc}$  gives  $\text{CH}_2\text{Cl.CH}(\text{OEt})(\text{OAc})$  (Bauer, *A.* 184, 176).—

6. Dry metallic zinc acts vigorously, producing HCl, ZnCl<sub>2</sub>, EtCl, alcohol, CH<sub>3</sub>Cl, CHO, and a condensation product of the alcoholate of the latter, C<sub>2</sub>H<sub>5</sub>Cl<sub>2</sub>O<sub>2</sub> (Wislicenus, A. 226, 271).—7. Zinc in presence of water produces aldehyde, Et<sub>2</sub>O, alcohol and chloro-aldehyde, besides small quantities of crotonic-aldehyde, chloro-acetal, β-oxy-chloro-ether (CH<sub>3</sub>OH·CHCl·OEt) and (CH<sub>3</sub>Cl·CH(OEt)<sub>2</sub>·O (W.).—8. In ethereal solution with ZnEt<sub>2</sub> it forms CH<sub>3</sub>Cl·CH<sub>2</sub>·OEt, 'ethyl chloro-ether' (ethyl chloro-butyl oxide). 9. Excess of ZnEt<sub>2</sub> gives ethyl hexyl-ether, CH<sub>3</sub>Et·CH<sub>2</sub>·OEt.—10. With ZnMe<sub>2</sub> it gives CH<sub>3</sub>Cl·CHMe·OEt, i.e. ethyl chloro-isopropyl ether.—11. Dichloro-di-ethyl oxide (25 g.) heated with aniline (50 g.) and water forms indole (Berlinerblau, M. 8, 180).—12. Phenol forms C<sub>2</sub>H<sub>5</sub>(C<sub>2</sub>H<sub>5</sub>OH)<sub>2</sub> (Wislicenus a. Reinhardt, A. 243, 151).—13. (a) Naphthol forms amorphous C<sub>2</sub>H<sub>5</sub>(C<sub>2</sub>H<sub>5</sub>OH)<sub>2</sub>. (b) naphthol gives crystalline plates of C<sub>2</sub>H<sub>5</sub>ClO [174°] (Wislicenus a. Zwanziger, A. 243, 165).—14. Resorcin, Pyrocatechin, and Hydroquinone form compounds of the form C<sub>2</sub>H<sub>5</sub>(C<sub>2</sub>H<sub>5</sub>O<sub>2</sub>H)<sub>2</sub> (Wislicenus a. Siegfried, A. 243, 171).—15. Thiourea forms thiazoline (Hantsch a. Traumann, B. 21, 938).

**Di-chloro-di-ethyl oxide** (CH<sub>2</sub>·CHCl)<sub>2</sub>O. *Ethylidene oxychloride*. (117°). S.G.  $\mu^2$  1.136. V.D. 5.08 (calc. 4.95). From dry aldehyde cooled by a freezing mixture by passing dry HCl into it. The product is dried with CaCl<sub>2</sub> and distilled (Lieben, C. R. 46, 662; Kessel, A. 176, 44; 176, 44; Geuther, A. 218, 16).

**Reactions.**—1. Water on warming decomposes it into HCl and aldehyde.—2. Alcohol forms chloro-diethyl oxide (CH<sub>2</sub>·CHCl)<sub>2</sub>O + 2HOEt = 2CH<sub>2</sub>·CHCl(OEt) + H<sub>2</sub>O.—3. NaOEt converts it (in ethereal solution) into aldehyde-resin, acetal, and alcohol.—4. Alcoholic sodium ethylate forms, besides the same products, a liquid (CH<sub>2</sub>·CH(OEt)<sub>2</sub>·O (153° cor.) S.G.  $\mu^2$  .891. This is sparingly sol. water. It decomposes in a few days into acetal and aldehyde: (CH<sub>2</sub>·CH(OEt)<sub>2</sub>·O = CH<sub>2</sub>·CH(OEt) + CH<sub>3</sub>·CHO.—5. Dry NaOEt gives CH<sub>2</sub>·CH(OEt)<sub>2</sub>·O·CHCl·CH<sub>3</sub> (146°), a liquid, decomposed by hot water (Hanriot, A. Ch. [5] 25, 223).—6. MeOH and NaOMe form similarly (CH<sub>2</sub>·CH(OMe)<sub>2</sub>·O (126°–127°). S.G.  $\mu^2$  .953. This also has an aromatic smell and splits up like the foregoing, though more slowly, into dimethyl acetal and aldehyde.—7. Sodium succinate gives O(CHMe·OCO)<sub>2</sub>C<sub>2</sub>H<sub>5</sub> (Geuther, A. 226, 228).—8. Zinc ethyl produces di-butyl oxide (CH<sub>2</sub>·CH<sub>2</sub>)<sub>2</sub>O.

**Tri-chloro-di-ethyl oxide** CHCl<sub>2</sub>·CHCl·OEt. (157°) (G.); (168°) (K.). From chloro-vinyl ethyl oxide and Cl<sub>2</sub> (Godefroy, C. R. 102, 869). Also from di-chloro-acetal and PCl<sub>5</sub> (Krey, J. 1876, 475). Occurs in the product of chlorination of ether. Fuming liquid; with NaOEt it gives CHCl<sub>2</sub>·CH(OEt)<sub>2</sub>. C<sub>2</sub> acid. aqueous KOH gives CCl<sub>2</sub>·CH<sub>2</sub>·OEt (145°).

**Tetra-chloro-di-ethyl oxide** CCl<sub>2</sub>·CHCl·OEt. Mol. w. 212. (190°) (P. a. P.); (c. 183°) (G.). S.G.  $\mu^2$  1.437;  $\mu^2$  1.418.

**Formation.**—1. From chlorine and ether at 90° in the dark.—2. From chloral alcoholate and PCl<sub>5</sub> (Henry, B. 4, 101, 435; Paternò a. Pisati, J. 1872, 303; G. 2, 333).—3. From di-chloro-vinyl ethyl oxide CCl<sub>2</sub>·CH·OEt and chlorine (Godefroy, C. R. 102, 869).

**Reactions.**—1. Conc. H<sub>2</sub>SO<sub>4</sub> gives chloral, HCl, and alcohol.—2. Heated with alcohol it gives tri-chloro-acetal CCl<sub>3</sub>·CH(OEt)<sub>2</sub>.—3. With dilute (10 p.c.) alcoholic potash it gives trichloro-vinyl-ethyl oxide CCl<sub>2</sub>·CCl·OEt.—4. H<sub>2</sub>S gives C<sub>2</sub>H<sub>5</sub>S<sub>2</sub>O [123°] and C<sub>2</sub>H<sub>5</sub>ClSO [72°] (Malaguti, A. 32, 29).

**Penta-chloro-di-ethyl oxide** CCl<sub>3</sub>·CCl<sub>2</sub>·OEt. (190°–210°). S.G. 1.65.

**Formation.**—1. The final product of the action of chlorine on ether in the dark (Jacobsen, B. 4, 217).—2. From CCl<sub>2</sub>·CCl·OEt and Cl (Busch, B. 11, 445). It is partly decomposed on boiling.

**Penta-chloro-di-ethyl oxide** CCl<sub>3</sub>·CHCl·OEt (235°). S.G.  $\mu^2$  1.577. From PCl<sub>5</sub> and CCl<sub>2</sub>·CH(OH)·O·CH<sub>2</sub>·CH<sub>2</sub>Cl, a compound of chloral and glycolic chlorhydrin (Henry, B. 7, 763).

**Hexa-chloro-di-ethyl oxide** (CHCl<sub>2</sub>·CHCl)<sub>2</sub>O. (250°). From PCl<sub>5</sub> and the hydrochloride of di-chloro-aldehyde (Paternò a. Pisati, G. 1, 461).

**Octo-chloro-di-ethyl oxide** C<sub>2</sub>H<sub>5</sub>Cl<sub>8</sub>O. Formed by the action of Cl on aldehyde hydrochloride in sunlight.

Crystals, smelling like camphor, may be sublimed (Roth, B. 8, 1017).

**Per-chloro-di-ethyl oxide** C<sub>2</sub>Cl<sub>10</sub>O. [69°]. S.G.  $\mu^2$  1.900. Formed by the action of chlorine in sunlight on ether (Regnault, A. 34, 27; Malaguti, A. Ch. [3] 16, 4). Dimetric octahedra (Nicklès, A. Ch. [3] 22, 28). Splits up on heating into C<sub>2</sub>Cl<sub>6</sub> and trichloro-acetyl chloride.

**CHLORO-ETHYL-OXY-TOLUQUINOLINE** v. CHLORO-OXY-METHYL-ETHYL-QUINOLINE.

**CHLORO-DI-ETHYL-DI-PHENYLETHANE** C<sub>2</sub>H<sub>5</sub>Cl<sub>2</sub> i.e. CH<sub>2</sub>Cl·CH(C<sub>6</sub>H<sub>5</sub>)<sub>2</sub>. (c. 268°). From ethyl-benzene, CH<sub>3</sub>Cl·CHCl·OEt, and H<sub>2</sub>SO<sub>4</sub> (Hepp, B. 7, 1414). On distillation it gives HCl and C<sub>2</sub>H<sub>5</sub>Cl.

**Eso-CHLORO-ETHYL-PHENYL METHYL KETONE** C<sub>2</sub>H<sub>5</sub>EtCl·CO·CH<sub>3</sub>. Formed, together with the two chloro-phthalic acids, by oxidising chloro-di-ethyl-benzene with chromic mixture (Istrati, A. Ch. [6] 6, 421). Liquid; not attacked by boiling alcoholic KOH, but converted into chloro-ethyl-benzoic acid by potash-fusion.

**CHLORO-TETRA-ETHYL-PHOSPHONIUM CHLORIDE** (ClCH<sub>2</sub>·CH<sub>2</sub>)<sub>2</sub>PEt<sub>2</sub>Cl. From PEt<sub>2</sub> and ethylene chloride in the cold (Hofmann, A. Suppl. 1, 276). Needles. Moist Ag<sub>2</sub>O converts it into an oxy-ethyl base CH<sub>2</sub>(OH)·CH<sub>2</sub>·PEt<sub>2</sub>OH.

**Salt.**—(C<sub>2</sub>H<sub>5</sub>Cl·PEt<sub>2</sub>Cl)<sub>2</sub>·PtCl<sub>4</sub>. Orange needles.

**CHLORO-ETHYL-PROPYL-GLYOXALINE**

C<sub>2</sub>H<sub>5</sub>·ClN<sub>2</sub>. Chlor-oxal-propylamine (236° cor.). V.D. = 5.65 (obs.). S.G.  $\mu^2$  1.09. From di-propyl oxamide by PCl<sub>5</sub>. Oil. V. sl. sol. water, miscible with alcohol, ether, or CHCl<sub>3</sub>. On reduction with HI it gives ethyl-propyl-glyoxaline (Wallach a. Schulze, B. 13, 516; 14, 423; A. 214, 312).

**Salts.**—(B<sup>+</sup>HCl)<sub>2</sub>·PtCl<sub>4</sub>.—B<sup>+</sup>HI.—B<sup>+</sup>AgNO<sub>3</sub>. Needles.

(Py. 3, 2). **CHLORO-ETHYL-QUINOLINE**

C<sub>2</sub>H<sub>5</sub>·ClN i.e. C<sub>2</sub>H<sub>5</sub>  $\begin{matrix} \text{CH}=\text{C}(\text{C}_2\text{H}_5) \\ | \\ \text{N}=\text{CCl} \end{matrix}$  [73°].

Prepared by the action of PCl<sub>5</sub> on ethyl-hydro-carbostyryl (Baeyer a. Jackson, B. 13, 120). Insol. water, v. sol. other solvents. Volatile with steam. Weak base.—(B<sup>+</sup>HCl)<sub>2</sub>·PtCl<sub>4</sub>. V. sol. alcohol, decomposed by water.

**Chloro-ethyl(?) -isoquinoline**  $C_{11}H_{10}NCl$ . [ $\alpha$ . 80°]. Formed by boiling the di-chloro-derivative [166°] with HI and P. Colourless crystals. By heating with HI and P to 200° it is completely dechlorinated (Gabriel, *B.* 20, 1206).

**Di-chloro-ethyl(?) -isoquinoline**  $C_{11}H_8NCl_2$ , probably  $C_6H_5$   $\begin{array}{c} O(C_6H_5) : CCl \\ | \\ OCl \end{array}$   $\rightarrow$  N [166°]. Formed by heating the imide of phenyl-di-methyl-carboxylic acid  $C_6H_5$   $\begin{array}{c} CM_2 : CO \\ | \\ CO : NH \end{array}$  with  $POCl_3$ ; if the product

is a derivative of ethyl-isoquinoline an isomeric change must have occurred during the reaction. Long colourless needles. By HI and P it is first reduced to the mono-chloro-derivative [80°] and then to the ethyl(?) -isoquinoline [65°] (Gabriel, *B.* 20, 1206).

#### DI-CHLORO-DI-ETHYL SULPHIDE

•  $(CH_3CH_2Cl)_2S$ . (217°). Formed by the action of PCl on  $S(CH_3CH_2OH)_2$ , obtained from glycol chlorhydrin and  $K_2S$  (V. Meyer, *B.* 19, 3259; 20, 1729). Oil. Very poisonous and violently inflames the skin (difference from di-ethyl sulphide).

**Tetra-chloro-di-ethyl sulphide**  $(C_2H_5Cl)_2S$ . (167°–172°). S.G. 1.547. A yellow oil formed by passing chlorine into di-ethyl sulphide, which is at first kept cool and in the shade (Riche, *A.* 92, 858). They appear also to be formed  $(C_2H_5Cl)_4S$  (189°–192°),  $(C_2H_5Cl)_2S$  (217°–222°) and  $(C_2Cl_5)_2S$  (?).

**Di-chloro-di-ethyl di-sulphide**  $(CH_3CH_2Cl)_2S_2$ . S.G. 1.346. From ethylene and  $Cl_2S_2$  at 100° (Guthrie, *A.* 119, 91; 121, 108). Pale yellow oil. Alcoholic KOH gives oily  $(CH_3OH.CH_2)_2S$ .  $HNO_3$  forms  $CH_3Cl.CH_2.SO_3H$  (Springer, Lecroquer, *Bl.* [2] 48, 629).

**Tetra-chloro-di-ethyl di-sulphide**  $(C_2H_5Cl)_4S_2$ . S.G. 1.599. Formed by passing ethylene through boiling  $S_2Cl_2$  (G.). Oil.

• **CHLORO-ETHYL SULPHOCYANIDE**  $Cl.C_2H_4.CNS$ . (203°). Formed by heating  $C_2H_5Br$  (100 g.), KCN (66 g.) and alcohol (250 c.c.) with inverted condenser. The product is filtered, distilled to 150° and the residue in the retort cooled in a freezing mixture.  $C_2H_5(CNS)$ , now crystallises out. The liquid portion is distilled (J. W. James, *C. J.* 35, 807, *J. pr.* [2] 20, 352; 31, 411). Formed in the same way from ethylene chloro-bromide (107°–109°) (James, *C. J.* 43, 39; 47, 365).

**Properties.**—Oil. Smells like mustard oil. Burns with violet flame. Soluble in alcohol and ether. Dissolves in hot water, but separates again on cooling.

**Reactions.**—1. Fuming  $HNO_3$  converts it into chloro-ethane sulphonic acid,  $Cl.C_2H_4.SO_3H$ . Ammonia, of course, will convert this into taurine. —2. Alcoholic potassic sulphocyanide converts it into  $C_2H_5(SCN)_2$ . —3. With aqueous  $Na_2SO_3$  in sunlight it forms  $C_2H_5(SCN)(SO_2Na)$ .

**DI-CHLORO-(a)-ETHYL-THIOPHENE**  $C_6H_4(C_2H_4)Cl_2S$  (286° cor.). A liquid formed by passing chlorine into cooled 'a'-ethyl-thiophene (Bonz, *B.* 18, 551).

**DI-CHLORO-ETHYL-TOLUENE (?)**.  $C_9H_7Cl_2$  (865°). Formed, together with propylene and chlorinated cresol by distillation of penta-chloro-thymol (Lallemand, *C. R.* 43, 875).

#### DI-CHLORO-EUXANTHIC ACID o. EUXANTHIC ACID.

**DI-CHLORO-FLUORENE**  $C_{12}H_6Cl_2$ . [126°]. Formed by passing chlorine into fluorene (from coal-tar) in chloroform (Hodgkinson & Matthews, *C. J.* 43, 170). Colourless plates. Oxidised by chromic mixture to di-chloro-di-phenylene ketone [158°].

**Tri-chloro-fluorene**  $C_{12}H_3Cl_3$ . [147°]. Formed by leading chlorine into a  $CS_2$  solution of fluorene for a long time (Holm, *B.* 16, 1082). White plates. Sl. sol. alcohol and ether.

**Penta-chloro-fluorene di-chloride**  $C_{12}H_2Cl_7$ . [104°]. From di-chloro-fluorene in chloroform by chlorine (H. a. M.). Long needles.  $CrO_3$  converts it into a yellow ketone (?) [104°]. Alcoholic KOH converts it into a red body (?  $C_{12}H_2Cl_6$ ) which is insol. alcohol, but crystallises from chloroform, petroleum or acetic acid [ $\alpha$ . 110°]. It is not attacked by  $HNO_3$  or  $CrO_3$ .

#### CHLORO-FLUORESCIN

$CO < \begin{array}{c} C_6H_4Cl \\ -O- \end{array} > C \begin{array}{c} C_6H_4(OH) \\ C_6H_4(OH) \end{array} O$ . Formed by heating chloro-phthalic anhydride [97°] with resorcin. V. sl. sol. water and  $CHCl_3$ . When freshly prepared it is sol. alcohol and ether, but it changes on keeping into an insoluble crystalline form; v. sol. acetic acid; insol.  $C_6H_6$ ; sol. aqueous KHO, and  $K_2CO_3$  forming a deep red solution, which when diluted shows a fluorescence like that of fluorescein (Graebe & Rée, *C. J.* 49, 530).

#### Di-chloro-fluorescein. Hydrate.

$C_{20}H_{12}Cl_2O_{10} \cdot (C_6H_4(OH)_2)_2$ . Formed by heating (8)-di-chloro-phthalic anhydride [151°] with resorcin at 200°. Loses aq when heated. Alkalis form a red solution with green fluorescence (Le Royer, *A.* 238, 357).

#### Tetra-chloro-fluorescein

$C_6Cl_4.C_2O_2.(C_6H_4OH)_2O$ . Formed by heating resorcin with tetra-chloro-phthalic anhydride (Graebe, *A.* 238, 333). Addition of acids to its solution in NaOH pps. the hydrate or ortho-compound, which at 180° is dehydrated. Insol. ether.

#### Diacetyl derivative

$C_6Cl_4.C_2O_2.(C_6H_4OAc)_2O$ . **Hydrate**  $C_6Cl_4.C_2O_2.(C_6H_4(OH)_2)_2$ . Ppd. by adding acids to a solution of the fluorescein in aqueous NaOH. Orange needles (from ether); insol. water, sl. sol. alcohol. Its alkaline solution is red with strong green fluorescence like fluorescein. At 180° it gives off  $H_2O$ .

#### Chloride $C_6Cl_4.C_2O_2.(C_6H_4Cl)_2O$ . [259°].

**CHLOROFORM  $CHCl_3$ . Tri-chloro-methane.** Mol. w. 119.5. [ $-70^\circ$ ] (Berthelot, *Bl.* [2] 29, 3). (80–9°) at 754.3 mm. (Schiff, *M.* 220, 95); (61.4°) (Thorpe); (62°) (Perkin, *C. J.* 45, 530). S.G. 1.4839;  $d_{20}^{20}$  1.4081;  $d_{20}^{20}$  1.5009;  $d_{20}^{20}$  1.4849. C.E. (11.8 to 60.9) .00138 (Schiff); (0°–10°) .001248 (Thorpe); (0°–50°) .0013368 (T.); see also Grimaldi, *G.* 17, 18. S. 987 at 0°; .775 at 55° (Chancel & Permentier, *C. R.* 106, 577). V.D. 4.12 (for 4.12). H.F.p. 24110 (Th.). H.F.v. 23530. M.M. 5.559 at 15.8°. S.H. 233 (Schüller, *P. Suppl.* 5, 116, 192).  $\mu$  1.451 (Forbes, *P. M.* [3] 35, 94). S.V. 84.6 (Schiff); 85.6 (Ramsay); 84.5 (Thorpe). Capillarity: Swan, *C. J.* 1, 174; *P. M.* [3] 33, 36. Compressibility: Grassi, *A. Ch.* [3] 81, 437.

**Formation.**—1. By the action of bleaching

powder on dilute alcohol (Soubeiran, *A. Ch.* [2] 48, 181; Soubeiran a. Mialhé, *A.* 71, 225) or on acetone (Liebig, *A.* 1, 198).—2. By the action of chlorine on marsh-gas in daylight, and ultimately in sunlight (Regnault, *A. Ch.* [2] 71, 380).—3. By passing a mixture of chlorine and methyl chloride through animal charcoal at 250°–350° (Damoiseau, *C. R.* 92, 42).—4. By the action of aqueous potash on chloral (Liebig, *A.* 1, 199).—5. By the action of nascent hydrogen on  $\text{CCl}_4$ .—6. By boiling tri-chloro-acetic acid with aqueous alkalis (Dumas, *A. Ch.* [2] 56, 115; *A.* 32, 113).—7. From iodoform and  $\text{PCl}_5$  (Gautier, *Bull.* [3] 13, 316).—8. From  $\text{CCl}_4$ , zinc, and dilute  $\text{H}_2\text{SO}_4$  (Geuther, *A.* 107, 212).

**Preparation.**—1. By mixing chloral with dilute caustic soda.—2. Bleaching powder (40 pts.), water (100 to 150 pts.), alcohol (4 to 10 pts.), and slaked lime (4 to 10 pts.) are distilled together. The distillate separates into two layers, the lower one being chloroform. This is freed from chlorine by shaking with potash, dried over  $\text{CaCl}_2$ , and rectified (Kessler, *J. Ph.* [3] 13, 162).

**Theory of the process.**—The bleaching powder is supposed first to convert the alcohol into chloral (*q. v.*), and the lime which is present (or formed) would then split this up into calcium formate and chloroform:  $8\text{CaO} \cdot \text{Cl}_2 + 2\text{C}_2\text{H}_5\text{O} = 2\text{C}_2\text{Cl}_3\text{HO} + 5\text{CaCl}_2 + 3\text{CaO} + 5\text{H}_2\text{O} = 2\text{CCl}_3\text{H} + \text{Ca}(\text{CHO})_2 + 5\text{CaCl}_2 + 2\text{CaO} + 4\text{H}_2\text{O}$ .

When alcohol of various strengths is poured on bleaching powder the distillate, which sometimes explodes after shaking well with water, gives an oil which can be separated by fractionating into the following portions:—

Fraction	1 pt. alcohol mixed with pts. of water					
	0	1	2	4	8	
60°–70°	2.4	3.4	50.5	89.1	98.1	per-centage composition of oil.
70°–80°	9.8	12.4	31.2	7.7	1.9	
80°–100°	12.3	31.6	12.2	3.1	—	
100°–150°	21.0	27.5	—	—	—	
150°–160°	50.6	21.0	—	—	—	
160°–180°	4.2	—	—	—	—	

The amount of chloro-acetal (150°–160°) is therefore greatly diminished by diluting the alcohol (Goldberg, *J. pr.* 132, 111). The yield of chloroform is never more than equal in weight to the weight of the alcohol used, this is less than one molecule of chloroform from two molecules of alcohol. Chloroform cannot be prepared from pure methyl alcohol by means of bleaching powder, although it is formed from commercial methyl alcohol (Belohoubek, *A.* 165, 349). Chlorinated compounds are formed by the action of bleaching powder on isopropyl, isobutyl, and isomyl alcohols; so that the alcohol used to prepare chloroform should not contain fusel oil (J. Regnault a. E. Hardy, *J. Ph.* [4] 30, 405).

**Properties.**—Characteristic odour and sweet taste, almost insoluble in water. When pure it is not turned brown by  $\text{H}_2\text{SO}_4$ . Chloroform reduces Fehling's solution, thus:  $\text{CHCl}_3 + 2\text{CuO} + 5\text{KHO} = \text{Cu}_2\text{O} + 3\text{KCl} + \text{K}_2\text{CO}_3 + 3\text{H}_2\text{O}$  (Baudrimont, *J. Ph.* [4] 9, 410). It dissolves fats and resins. A solution of iodine in chloroform is violet, but bromine forms a red solution. It is anæsthetic

(James Simpson, *A.* 65, 121) and antiseptic (Robin, *C. R.* 30, 52; Augendre, *C. R.* 31, 679). When a mixture of chloroform and water is kept at 0° for a long time with frequent shaking a hydrate  $\text{CHCl}_3 \cdot 18\text{aq}$  separates in long laminae. It is lighter than chloroform but heavier than water, and melts at 1.6° (Chancel a. Parmentier, *C. R.* 100, 27; cf. Sajohelyi a. Ballo, *B.* 4, 160).

**Detection.**—Chloroform may be distinguished from most other similar chlorinated hydrocarbons by boiling it with alcoholic potash and a primary amine (*e.g.* aniline), when the characteristic disgusting odour of the carbamines will be noticed (Hofmann, *B.* 3, 769). When the vapour of chloroform is passed through a red-hot tube chlorine is liberated, and will turn paper moistened with starch and potassium iodide blue (Ragzsky, *J. pr.* 46, 170; Luedeking, *Am.* 8, 858). Chloroform gives a reddish-purple colour (? rosolic acid) when poured upon the hot residue obtained by evaporating an alcoholic solution of phenol mixed with caustic potash (Guarascchi, *G.* 3, 401).

**Impurities.**—Chloroform that is to be used for surgical operations should not give any brown colour when shaken with  $\text{H}_2\text{SO}_4$  (Gregory, *Pr. E.* 1850, 391; cf. Vulpus, *Ar. Ph.* [3] 13, 37; 25, 998). The presence of alcohol causes opalescence when chloroform is mixed with water (Mialhé, *J. Chim. Méd.* [3] 4, 279), and a green colour with chromic mixture (Cottell, *J. Ph.* [3] 13, 359). The reduction of potassium permanganate may also be used as a rough index of the amount of alcohol, aldehyde, and other oxidisable substances present in chloroform (Jolles, *Chem. Zeit.* 11, 786).

**Estimation.**—By treating a chloroform solution with alcoholic potash the chlorine is obtained as chloride. The conditions for getting a theoretical yield have been determined by De Saint-Martin (*C. R.* 106, 492–496; cf. Chancel a. Parmentier, *C. R.* 106, 577).

**Reactions.**—1.  $\text{CrO}_3$  mixture gives  $\text{COCl}_2$ .—2. Zinc and dilute  $\text{H}_2\text{SO}_4$  convert it into  $\text{CH}_2\text{Cl}_2$  (Geuther, *A.* 107, 212; Richardson a. Williams, *C. N.* 18, 60).—3. Zinc dust converts it in presence of ammonia into methane (Perkin, *C. N.* 18, 106).—4. Boiled with alcoholic potash it forms potassium chloride and formate, thus:  $\text{CHCl}_3 + 4\text{KHO} = 3\text{KCl} + \text{CHO} \cdot \text{K} + 2\text{H}_2\text{O}$ .—5. With *sodic ethylate* it gives orthoformic ether,  $\text{CH}(\text{OEt})_3$  (Williamson a. Kay, *C. J.* 7, 224).—6. Mixed with ammonia and passed through a red-hot tube it reacts thus:  $\text{CHCl}_3 + \text{NH}_3 = \text{CNH} + 3\text{HCl}$ . Aqueous ammonia at 220° forms carbonic oxide, ammonium formate, and ammoniac chloride, thus:  $2\text{CHCl}_3 + 7\text{NH}_3 + 3\text{H}_2\text{O} = \text{C}_2\text{H}_4 + 6\text{NH}_4\text{Cl} + \text{HCO} \cdot \text{NH}_4$  (André, *C. R.* 102, 553).—7. Water at 220° forms  $\text{CO}$ , formic acid, and  $\text{HCl}$ .—8. Alcoholic  $\text{K}_2\text{S}$  forms potassium thioformate  $\text{H} \cdot \text{CO} \cdot \text{SK}$  (Nicol, *Tr. E.* 29, 681).—9. Aniline at 190° gives di-phenyl-form-amine  $\text{C}_6\text{H}_5\text{NH} \cdot \text{CH} \cdot \text{N} \cdot \text{C}_6\text{H}_5$  (Hofmann, *Pr.* 9, 229).—10. Bromine at 200° gives  $\text{CBrCl}_3$  (Paternò, *G.* 1, 593; Friedel a. Silva, *Bl.* [2] 17, 587).—11. With bromine (3 pts.) and iodine (1 pt.) at 150° it gives  $\text{CBr}_2\text{Cl}$  [70°] and  $\text{CBr}$ , [76°] (Bolas a. Groves, *C. J.* 24, 770).—12.  $\text{HNO}_3$  containing  $\text{NO}_2$  forms at 100° a small quantity of chloropierin (Mills, *C. J.* 24, 641).—13. Conc.  $\text{HIAq}$  at 125° gives  $\text{CH}_2\text{I}_2$  (Lieben, *Z.* [2] 4, 719).  $\text{PH}_3\text{I}$  and  $\text{ZnO}$  give  $\text{CH}_3\text{Cl}$  (Hofmann, *B.* 6, 801).—14. When passed over red-hot copper

some acetylene is formed (Berthelot, *C. R.* 50, 805).—16. *Potassium amalgam* also forms acetylene (Kletzinsky, *Z.* [2] 2, 127).—16.  $\text{K}_2\text{SO}_4$  at  $170^\circ$  forms  $\text{CH}_3(\text{SO}_3\text{K})_2$  and  $\text{CH}(\text{SO}_3\text{K})_2$  (Strecker, *Z.* [2] 4, 214).—17. *Sodium* acting on chloroform containing alcohol forms chloroethulmic acid  $\text{C}_2\text{H}_5\text{ClO}_2$  (Hardy, *A. Ch.* [3] 66, 840; *C. R.* 54, 470; cf. Kern, *C. N.* 31, 121).—18. The *copper-zinc couple* does not act on pure chloroform; in presence of alcohol at  $60^\circ$  methane is evolved, together with a small quantity of acetylene; in presence of water methane is evolved even at  $12^\circ$  (Gladstone & Tribe, *C. J.* 28, 508).—19.  $\text{SbCl}_5$  at  $100^\circ$  forms  $\text{CCl}_4$  (Lösner, *J. pr.* [2] 13, 418).—20. Electric sparks decompose chloroform forming  $\text{HCl}$  and  $\text{C}_2\text{Cl}_4$ ; in presence of air  $\text{COCl}_2$  is formed (J. Regnault, *J. Ph.* [5] 5, 504).—21. Potash added to a mixture of *acetone* (1 mol.) and chloroform (1 mol.) forms acetone-chloroform or oxy-isobutyro-trichloride  $(\text{CH}_3)_2\text{C}(\text{OH})\text{CCl}_3$ . There is also formed a liquid isomeric, possibly  $\text{CHCl}_2\text{CMe}_2\text{OCl}$  ( $170^\circ$ ). It is a strong poison and yields with benzene and  $\text{AlCl}_3$  chloro-di-phenyl-*tert*-butyl alcohol (289°); while with  $\text{PCl}_5$  it yields  $\text{C}_4\text{H}_9\text{ClO}$  ( $151^\circ$ ) (Willgerodt & Genieser, *J. pr.* [2] 37, 362). Potash (8 mols.) acting on chloroform (1 mol.) and acetone (2 mols.) forms  $\text{C}_4\text{H}_9\text{O}_3$  i.e.  $\text{CMe}_2(\text{O.CMe}_2\text{CO}_2\text{H})_2$ ; an acid which, like acetone-chloroform (*q. v.*), is converted into oxy-isobutyric acid by heating with water (Willgerodt, *B.* 20, 2445; *Bl.* [2] 39, 157; Engel, *Bl.* [2] 47, 499; *C. R.* 104, 688).—22. With  $\text{SO}_2$  it forms carbonic oxide,  $\text{ClSO}_2\text{H}$  and  $\text{Cl}_2\text{S}_2\text{O}_3$  (Armstrong, *Z.* 1870, 247).

**Combination.**—With aqueous  $\text{H}_2\text{S}$  at  $0^\circ$  it forms a crystalline compound  $\text{CHCl}_2\cdot 2\text{H}_2\text{S} \cdot 23\text{aq}$  (Loir, *C. R.* 34, 547; *J.* 1862, 560; Forcrand, *A. Ch.* [5] 28, 12).

#### CHLORO-FORMIC ACID $\cdot \text{ClCO}_2\text{OH}$ .

**Methyl ether.**  $\text{ClCO}_2\text{Me}$ . ( $71^\circ$  cor.). S.G. 1.236 (Roese, *A.* 205, 228). Formed by the action of  $\text{COCl}_2$  on methyl alcohol (Dumas, *A.* 10, 277; *A. Ch.* 58, 52; Meyer & Wüster, *B.* 6, 965). Formed also by the action of chlorine on gaseous methyl formate (Hentschel, *J. pr.* [2] 36, 211). **Preparation.**—To avoid formation of methyl carbonate proceed thus: Phosgene is freed from chlorine by passing through a flask full of pieces of antimony and powdered glass and placed in the water bath. The gas is passed into a few c.c. of chloro-formate of methyl at  $0^\circ$ . Methyl alcohol is added in small portions at a time, waiting each time until the phosgene goes through unabsorbed. Altogether not more than 150 c.c. of methyl alcohol should be used (A. Klepl, *J. pr.* [2] 26, 447). **Properties.**—Heavy oil; readily decomposed by boiling with water. Gives the tri-chloro-methyl ether when chlorine acts on it in sunlight. Intermediate compounds are  $\text{C}_2\text{H}_5\text{Cl}_2\text{O}$  and  $\text{C}_2\text{H}_5\text{Cl}_3\text{O}$ . The compound  $\text{C}_2\text{H}_5\text{Cl}_2\text{O}$  ( $109^\circ$  cor.) is a very pungent oil, S.G. 1.4741;  $d_4^{20}$  1.4786. It is decomposed by water into formic aldehyde,  $2\text{CO}_2$ , and  $\text{CO}$ ; while aniline forms  $\text{C}_6\text{H}_5\text{Cl}_2(\text{NPhH})\text{O}$  ( $45^\circ$ ); and fusion with  $\text{NaOAc}$  yields methylene diacetate ( $166^\circ$ ). The other compound,  $\text{C}_2\text{H}_5\text{Cl}_3\text{O}$  or  $\text{C}_2\text{H}_5\text{Cl}_4\text{O}$  ( $181^\circ$  cor.), S.G. 1.52, is a liquid, slowly decomposed by boiling water into  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{HCl}$ , and formic aldehyde (Hentschel, *J. pr.* [2] 36, 468).

**Tri-chloro-methyl ether**  $\text{CCl}_3\text{A}$ . ( $128^\circ$

cor.). S.G. 1.1653. V.D.  $94.3$  (calc. 99). Formed by chlorinating methyl formate in sunlight. Liquid; inflames the skin. Above  $300^\circ$  it changes into the isomeric  $\text{COCl}_2$ ; this change takes place slowly even on boiling. At a dull red heat it splits up into  $\text{CCl}_4$  and  $\text{CO}_2$ .  $\text{Al}_2\text{Cl}_6$  decomposes it in the same way (Hentschel, *J. pr.* [2] 36, 99, 305). **Reactions.**—1. Like  $\text{COCl}_2$ , it acts on  $\text{NaOAc}$  forming  $\text{NaCl}$ ,  $\text{CO}_2$ , and  $\text{Ac}_2\text{O}$ .—2.  $\text{MeOH}$  forms an oil, possibly  $\text{CCl}_3\text{O.CO.O.Me}$ ; it boils at  $164^\circ$  being split up into  $\text{COCl}_2$  and  $\text{Cl.CO.Me}$ .—3. Dry and aqueous ammonia forms urea but not tri-chloro-acetamide.—4. Aniline forms di-phenyl-urea and phenyl cyanate. —5. Benzene and  $\text{AlCl}_3$  give  $(\text{C}_6\text{H}_5)_2\text{CCl}$ .—6. Phenol gives  $\text{C}_6\text{H}_5\text{O.CO.Cl}$ .

**Ethyl ether**  $\text{ClCO}_2\text{Et}$ . Mol. w. 108. ( $94^\circ$ ). S.G. 1.139. V.D. 8.82. **Preparation.**—By passing  $\text{COCl}_2$  into well-cooled alcohol (Dumas, *A. Ch.* [2] 54, 226; Cloez, *A. Ch.* [3] 17, 303; Cahours, *A. Ch.* [3] 19, 346; Klepl, *J. pr.* [2] 26, 468; Wilm & Wischin, *A.* 147, 150); or by dropping alcohol into liquid  $\text{COCl}_2$  standing in a freezing-mixture (Hentschel, *B.* 18, 1177). **Properties.**—Pungent liquid; decomposed by hot, but not by cold, water. **Reactions.**—1. With alcohol it forms carbonic ether, reacting thus:  $\text{ClCO}_2\text{Et} + \text{HOEt} = \text{EtO.CO}_2\text{Et} + \text{HCl}$ .—2. With sodium it reacts in this way:  $2\text{ClCO}_2\text{Et} + \text{Na} = 2\text{NaCl} + \text{CO} + \text{CO}_2\text{Et}_2$ .—3. With  $\text{ZnMe}_2$  it reacts in the following manner:  $2\text{ClCO}_2\text{Et} + \text{ZnMe}_2 = \text{ZnCl}_2 + 2\text{CO}_2 + 2\text{C}_2\text{H}_5 + 2\text{CH}_4$  (Bulterov, *Z.* 1863, 484).—4. With ammonia it forms carbamic ether,  $\text{NH}_2\text{CO}_2\text{Et}$ .—5.  $\text{AlCl}_3$  splits it up into  $\text{CO}_2$  and  $\text{EtCl}$ .—6. Benzene and  $\text{AlCl}_3$  give ethyl-benzene (Rennie, *C. J.* 41, 33).—7.  $\text{ZnCl}_2$  gives  $\text{CO}_2$ ,  $\text{EtCl}$ ,  $\text{HCl}$ , and ethylene (Ulsch, *A.* 226, 281).—8. Sodium amalgam converts it into formic acid (Geuther, *A.* 205, 225).—9.  $\text{NaOCl}_2\text{H}_3$  gives  $(\text{C}_2\text{H}_5\text{O})\text{CO}(\text{OEt})_2$  (Fatiannoff, *Z.* 1864, 77).—10.  $\text{Na}_2\text{S}$  gives  $\text{S}(\text{CO}_2\text{Et})_2$  (V. Meyer, *B.* 2, 297).—11. Potassium cyanate forms the following crystalline bodies: (a)  $\text{C}_2\text{H}_5\text{N}_3\text{O}_2$  or  $\text{C}_2\text{H}_5\text{O}(\text{CO}_2\text{Et})_2$  ( $119^\circ$ ); (b)  $\text{C}_2\text{H}_5\text{N}_3\text{O}_2$  or  $\text{C}_2\text{H}_5\text{O}_2\text{Et}(\text{CO}_2\text{Et})_2$  ( $123^\circ$ ); (c)  $\text{C}_2\text{H}_5\text{N}_3\text{O}_2$  or  $\text{C}_2\text{H}_5\text{O}_2\text{Et}(\text{CO}_2\text{Et})_2$  ( $107^\circ$ ); (d)  $\text{NH}(\text{CO}_2\text{Et})_2$  ( $50^\circ$ ); and (e)  $\text{C}_2\text{H}_5\text{N}_3\text{O}_2$  (Wurts & Henninger, *C. R.* 100, 1419; *Bl.* [2] 44, 26).—12. With  $\text{KNCS}$  in presence of alcohol it forms carbonic ether and allophanic ether (Wilm, *A.* 192, 243):  $2\text{ClCO}_2\text{Et} + 2\text{KNCS} + 3\text{HOEt} = 2\text{KCl} + 2\text{Et}_2\text{CO} + \text{C}_2\text{H}_5\text{N}_3\text{O}_2\text{Et}$ .—13. With thio-urea it forms  $\text{NH}_2\text{CS.NHCO}_2\text{Et.HCl}$  ( $117^\circ$ ) (Pawlewski, *B.* 21, 401).—14. With di-phenyl-thio-urea it forms di-phenyl-thio-allophanic acid  $\text{NHPh.CS.NPh.CO}_2\text{Et}$ .—15. With phenyl-thio-urea it forms phenyl-allophanic acid  $\text{NHPh.CS.NH.CO}_2\text{Et}$ .—16. With acetyl-phenyl-thio-urea it forms  $\alpha$ -phenyl-thio-allophanic acid  $\text{NH}_2\text{CS.NPh.CO}_2\text{Et}$ .—17. Cyanethine forms cyanethine carboxylic acid (E. v. Meyer & Schöne, *J. pr.* [2] 30, 123).—18. Quinoline forms ethyl-quinoline:  $\text{C}_6\text{H}_5\text{N} + \text{ClCO}_2\text{Et} = \text{C}_6\text{H}_5\text{Et.NHCl} + \text{CO}_2$  (M. A. S.).

**Chloro-ethyl ether**  $\text{ClCO}_2\text{CH}_2\text{CH}_2\text{Cl}$ . ( $150^\circ$ – $160^\circ$ ). From glycolic chlorhydrin and  $\text{COCl}_2$  in the cold (J. Nemirowsky, *J. pr.* [2] 31, 178). The product is mixed with  $\text{K}_2\text{CO}_3$  and extracted with ether. Colourless, fuming, pungent liquid, insol. water, sol. alcohol and ether. **Reactions.**—1. Not decomposed by boiling water. 2. Converted by boiling dilute potash into glycol,

## CHLORO-FORMIC ACID.

potassium chloride, and potassium carbonate.—

3. Converted by ammonia into the carbamate of chloro-ethyl, as follows:  $\text{Cl.CO.O.C}_2\text{H}_4\text{Cl} + 2\text{NH}_3 \rightarrow \text{NH}_2\text{HCl} + \text{H}_2\text{N.CO.O.C}_2\text{H}_4\text{Cl}$ .—4. With aniline it reacts, forming the corresponding compound  $\text{NPhH.CO.O.C}_2\text{H}_4\text{Cl}$  (phenyl-carbamie acid).

*Propyl ether*  $\text{ClCO}_2\text{Pr}$ . (115° cor.). S.G. 1.09. Liquid; more stable than methyl ether (Roese, A. 205, 229).

*Isopropyl ether*  $\text{ClCO}_2\text{Pr}$ . (95°). S.G. 1.144 (Spica, G. 17, 168). Gives with  $\text{NH}_3$  isopropyl carbamate  $\text{NH}_2\text{CO}_2\text{Pr}$  [37°].

*Isobutyl ether*  $\text{ClCO}_2\text{C}_4\text{H}_9$ . (129° cor.). S.G. 1.053 (Rosen, cf. Myllius, B. 5, 972). Ammonia converts it into isobutyl carbamate  $\text{NH}_2\text{CO}_2\text{C}_4\text{H}_9$  [55°].

*Amyl ether*  $\text{ClCO}_2\text{C}_5\text{H}_{11}$ . (153°) (S.); (154° cor.) (R.). S.G. 1.032. From  $\text{COCl}_2$  and amyl alcohol (Schöne, J. pr. [2] 32, 246).

*Phenyl ether*  $\text{ClCO}_2\text{C}_6\text{H}_5$ . (187°). From the tri-chloro-methyl ether and  $\text{NaOPh}$  (Hentschel, J. pr. [2] 36, 316).

*Amide*  $\text{Cl.CO.NH}_2$ . [50°]. (62°). Formed by passing dry  $\text{COCl}_2$  into  $\text{NH}_3$  at 400° (Gattermann a. Schmidt, B. 20, 858). Flat needles, with unpleasant odour. Changes on keeping into cyamelide with evolution of  $\text{HCl}$ . Decomposed by water into  $\text{CO}_2$  and  $\text{NH}_4\text{Cl}$ . With toluene and  $\text{AlCl}_3$  it gives the amide of *p*-toluic acid; other aromatic hydrocarbons and phenol ethers act similarly. Amines yield alkyl-ureas. Aqueous  $\text{NaOH}$  forms cyanic acid. Alcohols in small quantities form allophanic ethers, in excess they give carbamic ethers.

*Methylamide*  $\text{Cl.CO.NHMe}$  'Methyl-urea-chloride'. [90°]; (94°); colourless plates. Obtained by passing carbonyl chloride  $\text{COCl}_2$  over dry methylamine hydrochloride heated to 140°. Distilled over lime it yields methyl cyanate  $\text{OC.NMe}$ . Decomposed by water.

*Ethylamide*  $\text{Cl.CO.NHEt}$  'Ethyl-urea-chloride'. (32°); colourless liquid. Obtained by passing  $\text{COCl}_2$  over dry ethylamine hydrochloride heated to 250°–270°. Distilled over lime it yields ethyl cyanate  $\text{OC.NEt}$ . On conversion into vapour it dissociates into ethyl cyanate and  $\text{HCl}$ , which recombine on cooling. In most of its reactions it gives the same products as ethyl cyanate (Gattermann a. Schmidt, B. 20, 118; A. 244, 84).

*Di-methyl-amide*  $\text{Cl.CO.NMe}_2$ . Colourless liquid. Sol.  $\text{C}_2\text{H}_5$  ether, and  $\text{CS}_2$ . Prepared by the action of carbonyl chloride ( $\text{COCl}_2$ ) on dimethylamine. Is slowly decomposed by water into  $\text{CO}_2$  and  $\text{NHMe}_2\text{HCl}$  (Michler a. Escherich, B. 12, 1162).

**CHLORO-FORMYL-TRICARBOXYLIC ACID**  
v. CHLORO-METHANE-TRICARBOXYLIC ACID.

**CHLORO-FUMARIC ACID**  $\text{C}_2\text{HCl}(\text{CO}_2\text{H})_2$ . [191°].

**Preparation.**—1. Chlorine is passed to saturation into succinyl chloride. Methyl alcohol is added to the product as long as  $\text{HCl}$  escapes. The liquid is then boiled. On cooling, methyl chloro-fumarate, [102°], separates. The filtrate is poured into water, when a further quantity of this body is thrown down.  $\text{HCl}$  at 140° decomposes the ether forming the acid (Kauder, J. pr. [2] 81, 24).—2. Tartaric acid (50 g.) and  $\text{PCl}_5$  (275 g.) are heated with inverted condenser. The product is distilled to 130° and the residue

mixed with water. The solution is shaken with ether and the ether evaporated (Perkin a. Duppa, A. 115, 105; 129, 373; C. J. Proc. 4, 75).

**Properties.**—Clumps, from alcohol and benzene. V. sol. water, alcohol, and ether, s. sol. benzene and ligroin. May be sublimed unaltered.

**Constitution.**—Perkin considers it to be a derivative of fumaric acid because it is very soluble in water. The fact that it sublimes without forming an anhydride would indicate that it is a derivative of maleic acid (Kauder).

**Reactions.**—1. *Sodium amalgam* forms succinic acid (Perkin, A. 129, 375).—2. Dissolved in cold water and the equivalent of aniline added it gives a crystalline pp. of the acid aniline salt,  $\text{CO}_2\text{H.CH.CCl}(\text{CO}_2\text{H}).\text{NH}_2.\text{Ph}$ . [178°]. An aqueous solution may be kept for weeks without undergoing any change. On boiling the aqueous solution, it behaves like the corresponding bromo-fumarate, although less readily (Michael, Am. 9, 180).

**Salts.**—**KHA'**. Transparent prisms.—**BaA'** 8aq. Clumps.—**AgA'**.

**Methyl ether.**  $\text{Me.A}'$ . (224°).

**Ethyl ether.**  $\text{Et.A}'$ . (245°). S.G. 22 1.178. From tartaric ether and  $\text{PCl}_5$  (Henry, A. 156, 178; Claus, A. 191, 80).

**Amic ether**  $\text{C}_2\text{HCl}(\text{CO}_2\text{Et})(\text{CONH}_2)$ . [102°]. From chlorofumaric ether and alcoholic  $\text{NH}_3$  (Claus a. Voeller, B. 14, 150). Tables.

**Imide**  $\text{C}_2\text{HClO.NH}$ . [131°]. Large colourless plates. Sol. water, alcohol and ether. Formed by chlorination of succinimide (Ciamician a. Silber, B. 16, 2394).

**Chloro-fumaric acid**  $\text{C}_2\text{HCl}(\text{CO}_2\text{H})_2$ . [173°]. (c. 190°). White pp. consisting of microscopic needles. V. sol. alcohol, water, and ether. Formed by the combination of acetylene-di-carboxylic acid with  $\text{HCl}$ .

**Salts.**—**A'K<sub>2</sub>**: large sparingly soluble prisms.—**A'Ag<sub>2</sub>** aq: fine crystalline pp.—**A'Pb** 2aq: amorphous pp. becoming crystalline (Baudrowski, B. 15, 2695).

V. also CHLORO-MALEIC ACID.

**TETRACHLORO-GALLICIN**  $\text{C}_2\text{H}_2\text{Cl}_4\text{O}_2$ . From tetra-chloro-phthalic anhydride and pyrogallol at 200° (Graebe, A. 238, 387). At 180° it gives off 2aq becoming  $\text{C}_2\text{H}_2\text{Cl}_4\text{O}_2$ .

**CHLOROGENINE** v. ALSTONINE.

**β-CHLORO-GLUTACONIC ACID**

$\text{HO}_2\text{C.CH.CCl}(\text{CH}_2\text{CO}_2\text{H})$ . [129°]. Formed by the action of  $\text{PCl}_5$  (16 pts.) upon acetone-di-carboxylic ether  $\text{CO}(\text{CH}_2\text{CO}_2\text{Et})_2$  (5 pts.) at 100°, and saponification of the ether with conc.  $\text{HCl}$ ; yield: 50–60 p.c. of the theoretical. The reaction is probably due to the intermediate formation of  $\text{CCl}_2(\text{CH}_2\text{CO}_2\text{Et})_2$ . White needles (chloroform) or plates (hot benzene). V. sol. water, alcohol, and ether, less in chloroform, insol. cold benzene. By zinc-dust and acetic acid it is reduced to glutaconic acid [132°]; by sodium amalgam to glutaric acid. By alcoholic  $\text{KOH}$  it is converted into glutinic acid  $\text{HO}_2\text{C.CH}_2\text{CH}_2\text{CO}_2\text{H}$  (Burton a. Peckmann, B. 20, 145).

**DI-CHLORO-GLUTAZINE** v. DI-CHLORO-DI-OXY-AMIDO-PYRIDINE.

**TRI-CHLORO-ISOGLYCERIC ACID** v. TRI-CHLORO-PYRUVIC ACID.

**DI-CHLORO-GLYCOCOLL** v. DI-CHLORO-AMIDO-ACETIC ACID.

**DI-CHLORO-GLYCOLLIC ACID.** The dialkyl ethers  $\text{CCL}_2(\text{OR})\text{CO}_2\text{R}'$  of this acid are the primary products of the action of  $\text{PCl}_5$  upon oxalic ethers. On distillation under ordinary atmospheric pressure they split off alkyl chlorides, and are converted into the chloroglyoxylic ethers  $\text{Cl.CO.CO}_2\text{R}'$  (Anschütz, B. 19, 2158).

**Di-n-propyl ether**  $\text{CCL}_2(\text{OPr})\text{CO}_2\text{Pr}$ : (111° at 12mm.); colourless liquid. Formed by the action of  $\text{ePCl}_5$  upon mono-propyl oxalate  $\text{C}_2\text{O}_2(\text{OH})(\text{OPr})$ .

**Di-isoamyl ether**  $\text{CCL}_2(\text{OC}_4\text{H}_9)\text{CO}_2\text{C}_4\text{H}_9$ : (152° at 13mm.); colourless liquid. Formed by the action of  $\text{PCl}_5$  upon mono-isoamyl oxalate (Anschütz a. Schönfeld, B. 19, 1443).

**DI-CHLORO-GLYCOLLO-NITRILE**  
 $\text{CCL}_2(\text{OH})\text{CN}$ .

**Methyl derivative**  $\text{CCL}_2(\text{OMe})\text{CN}$ . (149°). S.G. 1.33. From di-chloro-acetonitrile and  $\text{NaOMe}$  (Bauer, A. 229, 168). Pleasant smelling liquid, nearly insol. water, but slowly decomposed by it. V. sol. alcohol, ether, and light petroleum. Changes on keeping into a solid isomeride.

**Ethyl derivative**  $\text{CCL}_2(\text{OEt})\text{CN}$ . (161°). S.G. 1.339. V.D. 153-24. Polymerises forming a white solid. [171°].

**Propyl derivative**  $\text{CCL}_2(\text{OPr})\text{CN}$ . (183°). S.G. 1.238. V.D. 174.

**Isobutyl derivative**  $\text{CCL}_2(\text{OC}_4\text{H}_9)\text{CN}$ . (196°). S.G. 1.23. V.D. 123.

These bodies combine with  $\text{PtCl}_2$ , forming compounds such as  $\text{CCL}_2(\text{OEt})\text{CNPtCl}_2$  (Bauer, A. 229, 182).

They are acted upon by dry  $\text{HBr}$  with formation of tri-chloro-aceto-nitrile, probably as a result of these reactions:

- (i.)  $\text{CCL}_2(\text{OMe})\text{CN} + \text{HBr} = \text{MeBr} + \text{CCL}_2(\text{OH})\text{CN}$ .
- (ii.)  $\text{CCL}_2(\text{OH})\text{CN} + \text{HCl} = \text{Cl.CO.CN}$ .
- (iii.)  $\text{CCL}_2(\text{OEt})\text{CN} + \text{HCl} = \text{CCL}_2\text{CO.NH}_2$

(Bauer, A. 229, 192). So also dilute  $\text{H}_2\text{SO}_4$  converts  $\text{CCL}_2(\text{OMe})\text{CN}$  into  $\text{CCL}_2\text{CO}_2\text{Me}$  and  $\text{CCL}_2(\text{OEt})\text{CN}$  into  $\text{CCL}_2\text{CO}_2\text{Et}$ .

**CHLORO-GLYOXIM**  $\text{C}_2\text{H}_3\text{ClO}_2\text{N}$ , i.e.  $\text{CCl}(\text{NOH})\text{CH}(\text{NOH})$ . [151°]. Formed by the action of hydroxylamine on chloral-hydrate (Nägeli, B. 16, 499). Glistening prismatic needles. Sol. water and alcohol.

**CHLORO-GLYOXYLIC ETHER**  $\text{Cl.CO.CO}_2\text{Et}$ . **Ethoxy-oxalyl chloride**. (131°). S.G. 1.216. V.D. 4-68 (calc. 4-71). Prepared by distilling oxalic ether with  $\text{PCl}_5$  (V.v. Richter, B. 10, 2228; C. C. 1878, 446; cf. Henry, B. 4, 599).

**Properties.**—Fuming liquid; decomposed by water with formation of oxalic acid. Alcohol gives oxalic ether. Alcoholic  $\text{NH}_3$  gives oxamic ether. Aniline forms  $\text{CO}_2\text{Et.CO.NPhH}$ .

**Reactions.**—1. **Zinc ethyl**, followed by water, forms oxy-hexoic ether  $\text{C}_6\text{H}_5(\text{OH})\text{CO}_2\text{Et}$  (Henry, B. 5, 949).—2. With **urea** it gives ethyl oxalurate,  $\text{NH}_2\text{CO.NH.CO.CO}_2\text{Et}$  (Henry, B. 4, 599; Salomon, B. 9, 376).—3. With  $\text{HgPh}_2$  it gives phenyl-glyoxylic acid (Claisen a. Morley, B. 11, 1596).—4. With **di-methyl-aniline** it gives di-methyl-amido-phenyl-glyoxylic acid.—5. With **di-phenyl-thiourea** dissolved in benzene it reacts vigorously, giving off  $\text{CO}_2$  and ethyl chloride and forming aniline and a compound which is probably thio-carbanilido-thio-oxanilide  $\text{NPhH.CS.NPh.CO.CS.NPhH}$  (v. Stojentin, J. pr.

[2] 32, 2). This body melts at [231°]. It dissolves in ether, sparingly in alcohol, not at all in water. It exhibits the following reactions: (a) Warmed with alcoholic  $\text{AgNO}_3$ , it forms  $\text{Ag}_2\text{S}$  and di-

phenyl-parabanic acid, [204°],  $\text{CO} \begin{matrix} \text{NPh} - \text{CO} \\ \text{NPh} - \text{CO} \end{matrix}$ . (b) Forms a red solution in aniline, which when warmed with dry alcohol and  $\text{AgNO}_3$ , forms oxalyl-tri-phenyl-guanidine,  $\text{C}(\text{NPh}) \begin{matrix} \text{NPh.CO} \\ \text{NPh.CO} \end{matrix}$  [230°].

(c) Fuming  $\text{HNO}_3$  forms a compound  $\text{C}_{13}\text{H}_9\text{N}_3\text{SO}_3$ . It melts at [235°], is insol. ether, benzene,  $\text{CS}_2$ , and light petroleum, and is readily decomposed by aqueous  $\text{NaOH}$ , p-nitraniline being formed.

(d) Alcoholic  $\text{NH}_3$  converts it into  $\text{C}_4\text{H}_9\text{N}_3\text{O}_3$ , a body which crystallises from alcohol in white needles, [220°], and which is itself converted by fuming  $\text{HNO}_3$  into another body,  $\text{C}_{13}\text{H}_9\text{N}_3\text{O}_3$ , sparingly soluble in water or alcohol, [235°].—6. With **phenyl thiourea**, dissolved in boiling benzene, it acts thus:  $2\text{NH}(\text{CS.NPh})_2\text{C}_2\text{O}_2 + \text{NH}_3 + \text{EtCl} + \text{H}_2\text{O}$ . The product is oxalyl-di-phenyl-di-thio-biuret. It forms slender needles (from alcohol) [215°].—7. When warmed with **phenyl-urea** it reacts as follows:  $\text{NPhH.CO.NH}_2 + \text{Cl.CO.CO}_2\text{Et} = \text{NPhH.CO.NH.CO}_2\text{Et} + \text{CO} + \text{HCl}$ , and also in the following way:  $\text{NPhH.CO.NH}_2 + \text{Cl.CO.CO}_2\text{Et} = \text{NPh} \begin{matrix} \text{CO} \\ \text{C}_2\text{O}_2 \end{matrix} \text{NH} + \text{EtCl} + \text{H}_2\text{O}$ . The chief products are, therefore, phenyl-allophanic ether, which forms needles (from alcohol), [120°], and phenyl-parabanic acid, which forms plates (from alcohol), [208°].—8. With **di-phenyl-urea** it forms di-phenyl-parabanic acid, [204°]:  $\text{NPhH.CO.NPhH} + \text{Cl.CO.CO}_2\text{Et} = \text{NPh} \begin{matrix} \text{CO} \\ \text{C}_2\text{O}_2 \end{matrix} \text{NPh} + \text{EtCl} + \text{H}_2\text{O}$ .—9. With **tri-phenyl-guanidine** it forms carbonyl-tri-phenyl-guanidine:

$(\text{NPhH})_3\text{C}:\text{NPh} + 2\text{Cl.CO.CO}_2\text{Et} = \text{NPh}:\text{C} \begin{matrix} \text{NPh} \\ \text{NPh} \end{matrix} \text{CO}_2\text{HCl} + \text{HCl} + \text{CO} + \text{Et}_2\text{C}_2\text{O}_2$ . The hydrochloride of this base forms concentric needles (from alcohol), [190°]; its nitrate,  $\text{B}^+\text{HNO}_3$ , forms octahedra (from alcohol), [185°]. By means of fuming nitric acid white needles of the formula  $\text{C}_{13}\text{H}_9\text{N}_3\text{O}_3$  may be got (M. v. Stojentin, J. pr. [2] 32, 1).

**CHLORO-GUANIDINE**  $\text{CH}_3\text{CIN}$ . From guanidine carbonate and chlorine (Kamenski, B. 11, 1602). Pale yellow crystalline powder. De-tonates about 147°.

**CHLORO-HEPTANE** v. **HEPTYL CHLORIDE**.

**Di-chloro-heptane**  $\text{C}_7\text{H}_{14}\text{Cl}_2$ , i.e.  $\text{Pr.CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{Cl}$ . **Heptylidene chloride**. (191° cor.). From ananthol and  $\text{PCl}_5$  (Limprihit, A. 103, 80). Converted by  $\text{Na}$  into heptylene. Alcoholic  $\text{KOH}$  gives chloro-heptylene.

**Di-chloro-heptane**  $\text{C}_7\text{H}_{14}\text{Cl}_2$ , i.e.  $\text{Pr.CCl}_2$  (181°). From di-n-propyl ketone and  $\text{PCl}_5$  (Tavildaroff, B. 9, 1442).

**Di-chloro-heptane**  $\text{Pr.CCl}_2$ . From di-isopropyl ketone and  $\text{PCl}_5$  (Henry, B. 8, 400). Splits up into  $\text{HCl}$  and  $\text{C}_7\text{H}_{14}\text{Cl}$  on distillation. Alcoholic  $\text{KOH}$  gives  $\text{C}_7\text{H}_{14}$ , (78°).

**CHLORO-HEPTENOIC ACID**  $\text{C}_7\text{H}_7\text{ClO}_2$ . From propyl-aceto-acetic ether and  $\text{PCl}_5$  (Demarçay, B. 10, 1178). Oil.

Chloro-heptenoic acid  $C_7H_9ClO_2$ . From isopropyl-aceto-acetic acid and  $PCl_5$  (D.). Oil.  
**CHLORO-HEPTYL ALCOHOL**  $C_7H_{15}ClO$ . (207°). S.G.  $\pm$  1.014. From octylene and  $HClO$  (De Clermont, Z. 1870, 411).

**CHLORO-HEXANE** v. **HEXYL CHLORIDE**.

Di-chloro-hexane  $C_6H_{12}Cl_2$ , i.e.

$CH_3CHClCH_2CH_2CHClCH_3$ . (170°-180°). From diallyl and fuming  $HCl$ aq (Wurtz, A. Ch. [4] 3, 161).

Di-chloro-hexane  $C_6H_{12}Cl_2$ . (c. 182°). S.G.  $\pm$  1.087. From the hexane of petroleum by chlorination (Cahours, A. Ch. [4] 1, 5).

Di-chloro-hexane  $C_6H_{12}Cl_2$ . (160°). Formed by chlorination of *diisopropyl* (Schorlemmer, A. 144, 187; Silva, B. 6, 36; 7, 953).

Di-chloro-hexane  $C_6H_{12}Cl_2$ , i.e.  $(CH_3)_2CCl.CCl(CH_3)_2$ . [160°]. From pinacene and  $POCl_3$  (Friedel, A. Silva, B. 6, 35). Crystalline.

Di-chloro-hexane  $(CH_3)_2CCl.CCl(CH_3)_2$ . [151°]. From pinacoline and  $PCl_5$  (Favorsky, J. pr. [2] 37, 393). Very volatile crystals. Gfcs with alcoholic potash  $CMe_2C_2CH$ .

Di-chloro-hexane  $C_6H_{12}Cl_2$ , i.e.  $OH_2CHClCHClCH_2CH_2CH_3$ . (c. 164°). S.G.  $\pm$  1.053. From chloro-ethyl-propyl-carbinol and  $PCl_5$  (Henry, Bl. [2] 41, 363). Alcoholic KOH gives  $C_6H_{11}Cl$  (122°).

Tri-chloro-hexane  $C_6H_9Cl_3$ . (c. 217°). S.G.  $\pm$  1.198. Formed by chlorinating *n*-hexane (Cahours, J. 1863, 525).

Hexa-chloro-hexane  $C_6H_6Cl_6$ . (c. 288°). S.G.  $\pm$  1.598. From *n*-hexane and  $Cl_2$  (C.).

**CHLORO-HEXENOIC ACID** v. **CHLORO-ETHYL CROTONIC ACID**.

Chloro-hexenoic acid  $C_6H_7ClO_2$ . [64°]. From di-methyl-aceto-acetic ether and  $PCl_5$  (D.).

**CHLORO-HEXYL ALCOHOL**  $C_6H_{13}ClO$ . *Allyl-chloro-propyl carbinol*. (c. 185°). S.G.  $\pm$  1.032.  $R_D$  58.3. From epichlorhydrin (150 g.), allyl iodide (273 g.), and zinc at 0°; the product being treated with water (Lopatkin, J. pr. [2] 30, 390). Oil. Oxidation gives chloro-oxy-valeric acid.

*Acetyl derivative*  $C_6H_{11}ClOAc$ . (c. 205°). S.G.  $\pm$  1.085;  $\pm$  1.048.  $R_D$  75.1.

Chloro-hexenyl alcohol  $C_6H_{11}ClO$ , i.e.

$CH_2 \begin{smallmatrix} CH \\ CHMe \end{smallmatrix} > CClCH_2OH$  (?). *Chloro-methyl-tetra-methylene-carbinol*. (c. 167°). From the following di-chloro-hexenyl alcohol by treatment with iron and acetic acid (Natterer, M. 5, 579). Liquid, sl. sol. water. Does not combine with Br. Gives with  $PCl_5$  a liquid  $C_6H_{11}Cl_2$  (100° at 20 mm.).

Di-chloro-hexenyl alcohol  $C_6H_{11}Cl_2O$ , i.e.  $CH_2 \begin{smallmatrix} CH \\ CH(CH_2Cl) \end{smallmatrix} > CClCH_2OH$  (?). (c. 117°) at 20 mm. From  $\gamma$ -di-chloro-crotonic aldehyde by successive treatment with  $ZnEt_2$  and water (Natterer, M. 5, 567). Thick liquid; v. sl. sol. water. Does not combine with Br.

*Acetyl derivative*  $C_6H_{11}ClOAc$ . (123°) at 20 mm. Converted by  $AgOAc$  at 110° into  $C_6H_9Cl(OAc)_2$  (140° at 20 mm.).

**CHLORO-HEXINENE** v. **HEXINYL CHLORIDE**.

Tetra-chloro-hexinene  $C_6H_4Cl_4$ . Formed by the action of  $PCl_5$  on mannite or dulcite (Bell, B. 12, 1273).

**CHLORO-HEXOIC ACID**  $C_6H_9ClO_2$ , i.e.  $CEt_2Cl.CO_2H$ . *Chloro-caproic acid*.

*Ethyl ether EtA'*. From  $PCl_5$  and the oxy-acid (derived from oxalic ether) (Markownikoff, B. 6, 1175). On distillation it gives  $HCl$  and hexenoic ether; sodium amalgam gives hexoic (di-ethyl-acetic) acid.

$\gamma$ -Chloro-isohexoic acid

$Me.CCl.CH_2.CH_2.CO_2H$ .

*Ethyl ether A'Et*: (88° at 12 mm.). Formed by saturating an absolute alcoholic solution of isocapro lactone (the lactone of oxy-hexoic acid) with  $HCl$ . On distillation it evolves  $HCl$  and yields pyroterebic ether (Brodt, B. 19, 514).

Tri-chloro-hexoic acid  $C_6H_5Cl_3O_2$ . [64°]. Formed by oxidation of the corresponding aldehyde by  $HNO_3$  (Pinner, B. 10, 1052). Zinc and  $HCl$  convert it into hexenoic acid.

**TRI-CHLORO-HEXOIC ALDEHYDE**

$C_6H_5Cl_3O$ . *Hexyl-chloral*. (213°). Occurs among the products of the chlorination of aldehyde (Pinner, B. 10, 1052). Potash splits it up into formic acid,  $C_5H_9Cl_2$ , and  $HCl$ .

**CHLORO-HEXYL ALCOHOL**  $C_6H_{13}ClO$ , i.e.  $CH_3CH_2CH_2CHClCH(OH)CH_3$ . *Methylchlorobutyl carbinol*. (170°). S.G.  $\pm$  1.018. From hexylene and  $HOCl$  (Domac, M. 2, 319). Iron and  $HOAc$  give *sec*-hexyl alcohol.

Chloro-hexyl alcohol  $C_6H_{13}ClO$ , i.e.  $CH_3CH_2CH_2CH(OH)CHClCH_3$  (?). *Hexylene chlorhydrin*. (171°). S.G.  $\pm$  1.014. From hexylene oxide and  $HCl$  (Henry, C. R. 97, 260). Oil, with sweetish taste.

*Acetyl derivative*  $C_6H_{11}ClOAc$ . (189°). S.G.  $\pm$  1.04.

*8*-Chloro-*n*-hexyl-alcohol

$CH_3CHClCH_2CH_2CH_2CH_2OH$  (?). *Hexylene 8-chlorohydrin*. Formed by heating the glycol with  $HCl$  (Lapp, B. 18, 3283). Colourless liquid of peculiar smell. Heavier than water, in which it is insoluble. By further heating with  $HCl$  it is converted into the di-chloride.

Chloro-hexyl alcohol  $C_6H_{13}ClO$ , i.e.  $CMe_2Cl.CMe_2.OH$ . [55°]. From  $CMe_2.CMe_2$  and  $HOCl$  (Eltekoff, J. R. 14, 390). Needles, smelling of camphor. Aqueous KOH forms pinacene; solid KOH gives hexylene oxide.

Di-chloro-hexyl alcohol  $C_6H_{11}Cl_2O$ . (208°). S.G.  $\pm$  1.4. From hexenyl alcohol and chlorine (Destrem, A. Ch. [5] 27, 58).

**CHLORO-HEXYLENE** v. **HEXYNYL CHLORIDE**.

Di-chloro-hexylene  $C_6H_8Cl_2$ , i.e.  $CH_2.CCl_2.CH_2.CH_2.CH=CH_2$ . *Allyl-chloracetot*. (150°). From methyl butenyl ketone and  $PCl_5$  (Henry, C. R. 87, 171). Heavy oil. Hot water reconverts it into the ketone. Alcoholic KOH gives  $C_6H_9Cl$ .

Di-chloro-hexylene  $C_6H_8Cl_2$ . From mesityl oxide and  $PCl_5$ . Smells like turpentine and resinifies in the air. Distillation over lime converts it into  $C_6H_9Cl$  (180°) (Baeyer, A. 140, 298).

Penta-chloro-hexylene  $C_6H_5Cl_5$ . [102°]. From quercite by treatment with  $HCl$ . Needles (Prunier, A. Ch. [5] 15, 1).

**m-CHLORO-HIPPURIC ACID**  $C_6H_7ClNO_2$ , i.e. [3:1]  $C_6H_4Cl.CO.NH.CH_2.CO_2H$ .

From hippuric acid,  $KClO_3$ , and  $HCl$  (Otto, A. 122, 129). Found in the urine after taking *m*-chloro-benzoic acid (Gräbe a. Schultzen, A. 142, 346). Viscid mass, sol. boiling water, mixes with alcohol and ether. Its alkaline solution turns

brown in air. Boiling conc. HCl gives glycocoll and *m*-chloro-benzoic acid.

Salts.—NaHA': 3aq: stellate groups of needles.—CaA': scales (from alcohol).—PbA': [100°].

Di-chloro-hippuric acid  $C_6H_4Cl_2NO_2$ , *i.s.* [1:2:4]  $C_6H_4Cl_2CO.NH.CH_2.CO.H$ . Formed together with the preceding by chlorinating hippuric acid with HCl and  $KClO_3$  (O.). Soft, semi-crystalline mass; less sol. water than the preceding acid. Conc. HCl splits it up into glycocoll and (1, 2, 4)-di-chloro-benzoic acid.

Salts.—NaA' aq: soft warty crystals.—CaA', 5aq (from hot water).—CaA', 9aq.—CaA', 10aq (from cold water).—BaA', 3aq.—PbA', 4aq.—(PbA'), PbO.—AgA': cauliflower-like masses (from hot water).

Ethyl ether EtA'. Oil.

CHLORHYDRIN  $\nu$  GLYCERIN.

Dichlorhydrin  $\nu$  DI-CHLORO-PROPYL ALCOHOL and Epichlorhydrin.

Trichlorhydrin  $\nu$  TRI-CHLORO-PROPANE.

CHLORO-HYDRACRYLIC ACID  $\nu$  CHLORO-OXY-PROPIONIC ACID.

CHLORO-HYDRO-ATROPIC ACID  $\nu$  CHLORO-PHENYL-PROPIONIC ACID.

CHLORO-HYDRO-CINNAMIC ACID  $\nu$  CHLORO-PHENYL-PROPIONIC ACID.

DI-CHLORO-HYDRO-CERULIGNON  $\nu$ .

Tetra-methyl-di-chloro-HEXA-OXY-DIPHENYL

CHLORO-HYDRONAPHTHOQUINONE

$C_{16}H_8Cl_2O_2$ , *i.s.*  $C_{16}H_8Cl_2(OH)_2$  [117]. From chloro-( $\beta$ )-naphthoquinone in acetic acid by passing in  $SO_2$  (Zincke, B. 19, 2498). Needles (from water).

Di-chloro-hydronephthoquinone  $C_{16}H_8Cl_2O_2$ , *i.s.*  $C_{16}H_8Cl_2(OH)_2$  [125°]. From di-chloro-( $\beta$ )-naphthoquinone and  $SO_2$  (Zincke, B. 19, 2500). Slender needles.

Di-chloro-( $\alpha$ )-hydronaphthoquinone  $C_{16}H_8Cl_2(OH)_2$  [135° uncor.]. Formed by shaking an ethereal solution of di-chloro-( $\alpha$ )-naphthoquinone with aqueous SnCl<sub>2</sub> till decolourised. Long colourless needles. V. sol. alcohol, ether, &c., insol. water. By air oxidation it is converted into the quinhydrone  $C_{20}H_{10}Cl_2O_4$ , which forms long violet-brown needles [250° uncor.] (Claus, B. 19, 1144; cf. Gräbe, A. 149, 6).

Di-acetyl derivative  $C_{16}H_8Cl_2(OAc)_2$  [236°].

CHLORO-HYDROQUINONE  $C_6H_4Cl(OH)_2$  [106°]. (263°). Prepared by boiling quinone with HCl (Levy a. Schultz, B. 13, 1427; A. 210, 137; cf. Wöhler, A. 51, 155; Wiechellhaus, B. 12, 1504). Also from chloroquinone and  $SO_2$  (Städeler, A. 69, 307). Monoclinic crystals, *abc*:*a* 2.77:1.231;  $\beta$  62° 3'. V. e. sol. water and alcohol, sl. sol. chloroform. On oxidation it gives chloroquinone. Heated with phthalic anhydride it produces a chlorinated quinizarine which is soluble in caustic soda with a blue colour. Combines with aniline with formation of  $C_6H_4Cl(OH)_2.2NH_4Ph$  [92°] which crystallises from hot water in glittering plates (Niemeyer, A. 228, 322). With *p*-toluidine it forms a compound melting at 90°. These compounds are not decomposed by crystallising from hot benzene.

Di-acetyl derivative  $C_6H_4Cl(OAc)_2$

[72°] (L. a. S.); [99°] (Scheid, A. 218, 216). Transparent prisms. Sol. alcohol.

Di-benzoyl derivative  $C_6H_4Cl(OBz)_2$  [130°]. Long needles. Easily soluble in hot alcohol, sparingly in cold.

( $\alpha$ )-Di-chloro-hydroquinone  $C_6H_4Cl_2(OH)_2$  [2:5:4:1]. [166°] (L. a. S.); [172°] (Kraft, B. 10, 800). Prepared by boiling chloro-quinone with HCl, or by passing dry HCl into a solution of chloroquinone in chloroform (Levy a. Schultz, B. 13, 1428; A. 210, 148). Formed also by reducing ( $\alpha$ )-di-chloro-quinone [159°] with aqueous  $SO_2$  (Städeler, A. 69, 312). Long needles (from boiling water). May be sublimed. On oxidation it gives ( $\alpha$ )-dichloro-quinone. Combines with aniline forming  $C_6H_4Cl_2(OH)_2.2NH_4Ph$  [113°], which crystallises in needles (from water), tables, or prisms (from benzene). The compound with *p*-toluidine melts at 115° (Niemeyer, A. 228, 328).

Di-acetyl derivative  $C_6H_4Cl_2(OAc)_2$  [141°]. Formed by the action of acetyl chloride on quinone or chloro-quinone. Monoclinic crystals (Schulz, B. 15, 653; A. 210, 148) *abc*:*a* 2.9:1.1:1.13;  $\beta$  72° 40'.

Di-benzoyl derivatives  $C_6H_4Cl_2(OBz)_2$  [185°]. Woolly needles, sol. benzene, insol. water.

( $\beta$ )-Di-chloro-hydro-quinone  $C_6H_4Cl_2(OH)_2$  [2:6:4:1]. [158°]. Formed by reduction of the corresponding quinone [120°] (Faust, A. 149, 155). Yellowish laminae (from dilute alcohol). Forns with *p*-toluidine a compound melting at 73°.

Di-acetyl derivative  $C_6H_4Cl_2(OAc)_2$  [67°]; fine needles.

Di-benzoyl derivative  $C_6H_4Cl_2(OBz)_2$  [103°]; colourless needles (Levy, B. 16, 1445).

Di-methyl ether  $C_6H_4Cl_2(OMe)_2$  [126°]. Formed by chlorinating di-methyl-hydroquinone (Habermann, B. 11, 1034). Small needles; may be sublimed.

Di-isobutyl ether  $C_6H_4Cl_2(OCH_2Pr)_2$  (Schubert, M. 3, 682).

Tri-chloro-hydroquinone

$C_6H_3Cl_3(OH)_2$  [134°]. Prepared, together with tetrachlorohydroquinone, by boiling ( $\alpha$ )- or ( $\beta$ )-dichloroquinone with HCl, and separated from tetra-chloro-hydroquinone by solution in water (Levy a. Schultz, B. 13, 1429; A. 210, 154). Formed also by reducing tri-chloro-quinone with  $SO_2$  (Städeler, A. 69, 321; Stenhouse, A. Suppl. 6, 214; Gräbe, A. 146, 25), and by oxidising benzene with  $KClO_3$  and  $H_2SO_4$  (Kraft, B. 10, 797; Carius, A. 142, 129). Flattened prisms. Its alkaline solutions turn brown in the air, ultimately forming di-chloro-di-oxy-quinone (chloranilic acid). It forms two compounds with aniline:  $C_6H_3Cl_3(OH)_2.NH_4Ph$  [60°], crystallising in small needles, and  $C_6H_3Cl_3(OH)_2.2NH_4Ph$  [67°], crystallising in trimetric tables. With phthalic anhydride it does not produce chlorinated quinizarine.

Di-acetyl derivative  $C_6H_3Cl_3(OAc)_2$  [153°]. Needles.

Di-benzoyl derivative  $C_6H_3Cl_3(OBz)_2$  [174°]. Needles.

Di-ethyl ether  $C_6H_3Cl_3(OEt)_2$  [68-5°]. Long needles.

Tetra-chloro-hydroquinone

$C_6Cl_4(OH)_2$  [232°] (Sutkowski, B. 19, 2316).

Prepared by boiling ( $\beta$ )-dichloro-quinone or tri-chloro-quinone with HCl (Levy a. Schultz, *B.* 13, 1429; *A.* 210, 255), or by passing HCl into a solution of tri-chloro-quinone in acetic acid (Niemeyer, *A.* 228, 324). Formed also by boiling tetra-chloro-quinone with  $\text{SnCl}_4$  with HClAq, with HBrAq, or with aqueous  $\text{SO}_2$ . Monoclinic pyramids;  $a:b:c = 3.0:1.2:58$ ;  $\beta = 76^\circ 34'$ . May be sublimed. Insol. water, v. sl. sol. benzene, v. sol. alcohol and ether. Reduces silver solution.  $\text{PCl}_5$  converts it into  $\text{C}_6\text{Cl}_4$ . A conc. solution in hot potash deposits, on cooling, prisms of  $\text{C}_6\text{Cl}_4(\text{OK})_2$ . A solution of this salt exposed to air forms  $\text{C}_6\text{Cl}_4\text{O}_2(\text{OK})_2$ . Combines with aniline, forming  $\text{C}_6\text{Cl}_4(\text{OH})_2\text{NH}_2\text{Ph}$  [115°].

**Di-acetyl derivative**  $\text{C}_6\text{Cl}_4(\text{OAc})_2$ . [245°].

**Di-benzoyl derivative**  $\text{C}_6\text{Cl}_4(\text{OBz})_2$ . [233°]. Sol. benzene, sl. sol. alcohol.

**Di-methyl ether**  $\text{C}_6\text{Cl}_4(\text{OMe})_2$ . [154°]. From di-methyl-hydroquinone and  $\text{C}_6\text{Cl}_4$  (Haber-mann, *B.* 11, 1035). Needles.

**Di-ethyl ether**  $\text{C}_6\text{Cl}_4(\text{OEt})_2$ . [112°]. From tetra-chloro-hydroquinone, KOH, EtI, and alcohol at  $140^\circ$  (Gräbe, *A.* 146, 19). Needles.

**Methyl ethyl ether**  $\text{C}_6\text{Cl}_4(\text{OMe})(\text{OEt})$ . [101°]. From  $\text{C}_6\text{H}_4(\text{OMe})(\text{OEt})$  and  $\text{Cl}$  (Fiala, *M.* 6, 912).

**Di-isobutyl ether**  $\text{C}_6\text{Cl}_4(\text{OCH}_2\text{Pr})_2$  (Schubert, *M.* 3, 632).

**Di-*p*-CHLORO-HYDROQUINONE-DI-CARBOXYLIC ETHER** v. **Di-*p*-CHLORO-DI-*p*-OXY-TEREPHTHALIC ETHER**.

**DI-CHLORO-HYDROQUINONE DI-SULPHONIC ACID**

$\text{C}_6\text{H}_2\text{Cl}_2\text{S}_2\text{O}_6$  i.e.  $\text{C}_6\text{Cl}_2(\text{OH})_2(\text{SO}_3\text{H})_2$ . From tetra-chloro-quinone and aqueous  $\text{KHSO}_4$  (Hesse, *A.* 114, 324; Greiff, *C. O.* 1863, 1044). The free acid is unstable. It gives an indigo-blue colour with  $\text{FeCl}_3$ . Alkaline solutions are oxidised by air to euthiochronic acid— $\text{KA}'\text{aq.}-(\text{NH}_4)\text{A}'\text{aq.}$

**Tri-chloro-hydroquinone sulphonic acid**  $\text{C}_6\text{H}_3\text{Cl}_3\text{SO}_3$  i.e.  $\text{C}_6\text{Cl}_3(\text{OH})(\text{SO}_3\text{H})$ . Formed, together with euthiochronic acid, by dissolving tri-chloro-quinone in warm aqueous  $\text{K}_2\text{SO}_5$  (Gräbe, *A.* 146, 55). Deliquescent needles.  $\text{FeCl}_3$  gives a blue colour.— $\text{KA}'\text{aq.}$  Alkaline solutions are oxidised in air to  $\text{C}_6\text{Cl}_3\text{OK}(\text{O})(\text{SO}_3\text{K})$ .

**CHLORO-HYDRO-THYMOQUINONE**

$\text{C}_{10}\text{H}_7\text{ClO}$ , i.e.  $\text{C}_6\text{HCl}(\text{C}_4\text{H}_5)(\text{OH})$ , [2:6:3:4:1]. [70°]. From thymoquinone and conc. aqueous HCl at  $0^\circ$  (Schniter, *B.* 20, 1317). Silky needles.

**Di-acetyl derivative**  $\text{C}_{10}\text{H}_5\text{Cl}(\text{OAc})_2$ . [88°]. Formed by the action of acetyl chloride on thymoquinone. Large crystals.

**Di-benzoyl derivative** [118°]. Colourless needles (Schulz, *B.* 15, 657).

**Di-chloro-hydrothymoquinone**

**Di-benzoyl derivative**  $\text{C}_{10}\text{H}_5\text{Cl}_2(\text{OBz})_2$ . [191°]. Formed by the action of benzoyl chloride on thymoquinone (Schulz, *B.* 15, 656). Sparingly soluble white needles.

**CHLORO-HYDROTOLUQUINONE.**

$\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}(\text{OH})_2$  [1:3or4:2:5]. [115° uncor.]. Formed by reduction of chloro-toluquinone [90°] with  $\text{SO}_2$ . Long colourless needles. Sublimable and volatile with steam (Claus a. Schweitzer, *B.* 19, 929).

**Chloro-hydro-toluquinone**  $\text{C}_6\text{H}_3\text{MeCl}(\text{OH})_2$ . [175°]. Obtained by the action of cold conc. HCl upon toluquinone. White plates or needles. V. sol. alcohol, ether, and hot water, sl. sol. ligroin (Schniter, *B.* 20, 2283).

**Di-chloro-hydro-toluquinone**

$\text{C}_6\text{HMeCl}_2(\text{OH})_2$ . [121°]. Formed by the action of HCl upon chloro-toluquinone. Not volatile with steam (Schniter, *B.* 20, 2288). Formed also by reducing di-chloro-toluquinone obtained from di-chlorinated *o*-cresol [54°] (Claus a. Schweitzer, *B.* 19, 937; cf. Stuthworth, *A.* 163, 274). Feathery crystals (from water). May be sublimed.

**Di-chloro-hydrotoluquinone**

$\text{C}_6\text{H}(\text{CH}_3)\text{Cl}_2(\text{OH})_2$ . [171° uncor.]. Formed by reduction of di-chloro-toluquinone [108°] (from di-chloro-*m*-cresol) with  $\text{SO}_2$ . Colourless needles. V. a. sol. alcohol, ether, &c., sol. hot water, sl. sol. cold (Claus a. Schweitzer, *B.* 19, 931).

**Acetyl derivative**  $\text{C}_6\text{HMeCl}_2(\text{OAc})_2$ . [124°] (Southworth).

**Tri-chloro-hydrotoluquinone**  $\text{C}_6\text{MeCl}_3(\text{OH})_2$ . [212°]. From tri-chloro-toluquinone and aqueous  $\text{SO}_2$  at  $100^\circ$  (Southworth; Borgmann, *A.* 152, 251; Hayduck, *A.* 172, 211; Claus a. Riemann, *B.* 16, 1603). Needles. Volatile with steam. Turns green in moist air.

**Di-acetyl derivative**  $\text{C}_6\text{MeCl}_3(\text{OAc})_2$ . [114°].

**Di-ethyl ether**  $\text{C}_6\text{MeCl}_3(\text{OEt})_2$ . [107°].

**Tetra-chloro-hydrotoluquinone**  $\text{C}_6\text{H}_2\text{Cl}_4\text{O}_2$ . From tetra-chloro-toluquinone and  $\text{SO}_2$  (Bräuninger, *A.* 185, 353). Needles (by sublimation).

**CHLORO-HYDROTOLUQUINONE DI-SULPHONIC ACID**  $\text{C}_6\text{MeCl}(\text{OH})_2(\text{SO}_3\text{H})_2$ . From tri-chloro-toluquinone and conc. aqueous  $\text{KHSO}_4$  (Borgmann, *A.* 152, 255).— $\text{KA}'$ : laminæ.

**CHLORO-HYDROXYLOQUINONE**

$\text{C}_6\text{HClMe}_2(\text{OH})_2$  [x:1:4:2:5]. [147°]. Formed, together with the di-chloro-compound, by treating xyloquinone (phlorthe) with conc. HCl (Carstanjen, *J. pr.* [2] 23, 421). Needles.  $\text{FeCl}_3$  colours its aqueous solution violet.

**Di-chloro-hydroxyloquinone**  $\text{C}_6\text{Cl}_2\text{Me}_2(\text{OH})_2$ . [180°]. Formed as above (C.) or by reducing di-chloro-xyloquinone with aqueous  $\text{SO}_2$  (Rad, *A.* 151, 164). Coloured violet by  $\text{FeCl}_3$ .

**DI-CHLORO-ICOSYLENE**  $\text{C}_{20}\text{H}_8\text{Cl}_2$ . S.G. 24 1.013. From  $\text{C}_{20}\text{H}_{10}$  and  $\text{Cl}$  (Lippmann a. Hawliczek, *B.* 12, 69).

**CHLOROIMIDO-CARBONIC ACID**  $\text{ClN:C}(\text{OH})_2$ .

**Methyl ether**  $\text{ClN:C}(\text{OMe})_2$ . [20°]. Formed by leading chlorine into a cooled solution of 80 pts. NaOH and 80 pts. KCN (96-98 p.c.) in 150 pts. of methyl alcohol. White crystalline solid. Its reactions are the same as those of the ethyl ether.

**Ethyl ether**  $\text{ClN:C}(\text{OEt})_2$ . [39°]. Formed by leading chlorine into a cooled solution of 60 pts. NaOH and 80 pts. KCN in 200 pts. of ethyl alcohol; the yield is 50 pts. of the pure product. Large colourless prisms. V. sol. alcohol and ether, insol. water. Rotates on water. Decomposes on distillation. Heated with aqueous  $\text{H}_2\text{S}$  it yields carbonic ether  $\text{NH}_4\text{Cl}$  and S. By dilute acids it is split up into carbonic ether, chloride of nitrogen and  $\text{NH}_3$ . From HI it liberates iodine. By warming with a solution of potassium arsenite it is reduced to imido-carbonic ether  $\text{HN:C}(\text{OEt})_2$  (Sandmeyer, *B.* 19, 862).

**TETRA-CHLORO-INDIGO**  $C_{16}H_2Cl_4N_2O_2$ . Very analogous to ordinary indigo. Obtained by the action of acetone and NaOH on di-chloro-nitrobenzoic aldehyde (Gnehm, B. 17, 752).

**DI-CHLORO-INDOLE**  $C_8H_5Cl_2N$  i.e.

$H_2\langle\begin{smallmatrix} CCl \\ NH \end{smallmatrix}\rangle CCl$ . [104°]. *Chloro-oxindole-halide*. From oxindole and  $PCl_5$ . Crystalline mass smelling like fœces. Colourless laminae (from hot water), v. e. sol. alcohol, ether, and benzene. Sol. alkalis. Can be methylated (Baeyer, B. 12, 446; 15, 786).

**DI-CHLORO-INDONAPHTHOQUINONE**

$H_2\langle\begin{smallmatrix} CO \\ CO \end{smallmatrix}\rangle CCl_2$ . [125°].

**Formation.**—Tetrachloro-(8)-naphthoquinone is dissolved in  $Na_2CO_3$  aq. HOAc is added and afterwards HCl and chromic acid, the mixture being gently warmed (Zincke, B. 21, 499).

**Properties.**—Plates (from dilute alcohol or HOAc).

**DI-CHLORO-ODHYDRIN**. **DI-CHLORO-iodo-PROPANE.**

**α- or β-CHLORO-iodo-ACRYLIC ACID**

$CH_2Cl.CCl.CO_2H$  or  $CHCl.CCl.CO_2H$ . [72°]. Formed by boiling propiolic acid with an ethereal solution of  $ClI$  (Stolz, B. 19, 538). Pearly crystals. Easily soluble in all solvents.

**Chloro-di-iodo-acrylic acid**  $C_3H_2O_2Cl_2$  i.e.  $Cl.CCl.CO_2H(?)$ . [143°]. Formed by boiling iodo-propionic acid with an ethereal solution of  $ClI$  (Stolz, B. 19, 538). Colourless glistening plates. Sparingly soluble in ligroin and cold water, more easily in alcohol and ether.

**o-CHLORO-iodo-BENZENE**  $C_6H_4ClI$  [2:1]. (above 233°) (Körner); (230°) (B. a. K.). S.G. 2:1.928. From o-chloro-aniline by displacing  $NH_2$  by  $I$  through the diazo-reaction (Körner, G. 4, 343; Beilstein a. Kurbatoff, A. 176, 33).

**p-Chloro-iodo-benzene**  $C_6H_4ClI$  [4:1]. [56°]. (227°). From p-chloro-aniline by displacing  $NH_2$  by  $I$ ; or from p-iodo-aniline by displacing  $NH_2$  by  $Cl$ .

**CHLOR-iodo-BENZOIC ACID**

$C_6H_4Cl.CO_2H$  [210°]. Formed by the action of an alcoholic solution of iodine upon chloro-salicylic acid [173°] (Smith a. Knerr, Am. 8, 95). Curved needles. Sol. boiling water.

**Salts.**—BaA'. Arborescent crystals.

**CHLORO-iodo-ETHANE**  $C_2H_4ClI$  i.e.  $CH_2Cl.CH_2I$ . *Ethylene chloro-iodide*. (140°) (Thorpe, C. J. 37, 189). S.G. 2:2.151 (Simpson); 2:2.164 (Th.). Formed by the action of  $ICl$  on ethylene or ethylene iodide (Maxwell Simpson, Pr. 11, 590; A. 125, 101; 127, 373; Suppl. 6, 254).

**Reactions.**—1. Alcoholic KOH gives  $C_2H_4Cl_2$ . 2. Moist  $Ag_2O$  gives glycol. — 3. Zinc and  $H_2SO_4$  gives ethylene. — 4. Silver forms ethylene and ethylene chloride (Friedel a. Silva, B. [2] 17, 242). — 5. Conc. HI forms, on heating,  $C_2H_6$  and  $C_2H_4I_2$ . — 6. Ammonia forms ethylene-diamine (Engel, B. [2] 48, 96).

**Chloro-iodo-ethane**  $CH_2Cl.CH_2I$ . *Ethylidene chloroiodide*. (118°). S.G. 2:2.054.

**Formation.**—Iodine (26 g.) is suspended in water (120 g.) and saturated with chlorine in the cold. The chloride of iodine is then shaken with ethylidene iodide, the product washed with dilute KOH and distilled.

**Preparation.**— $Al_2I_3$  (8 g.) is dissolved in  $CS_2$  (24 g.) and slowly added to ethylidene chloride (6 g.) dissolved in  $CS_2$  (6 g.) and kept at 0° The product is treated as above (Maxwell Simpson, Pr. 27, 424).

**Di-chloro-iodo-ethane**  $C_2H_4Cl_2I$ . (172°). S.G. 2:2.219. From  $C_2H_4Cl$  and  $ICl$  (Henry, C. R. 98, 518). Alcoholic KOH gives  $CH_2=CCl_2$  (37°).

**CHLORO-iodo-ETHYLENE**  $C_2H_2ClI$ . *Acetylene chloro-iodide*. (119° i. V.) (Plimpton); (115°) (Sabanejeff). S.G. 2:2.230 (P.); 2:2.154 (S.); 192:2.118 (S.). Formed by passing acetylene into a solution of  $ICl$  in HCl (Plimpton, C. J. 41, 392) or in ether (McGowan, P. E. 9, 589).

**Preparation.**—Chlorine is passed into water (6 pts.) containing iodine (1 pt.). The liquid is poured off from undissolved iodine, and acetylene is then passed in (Sabanejeff, A. 216, 264).

**Reactions.**—1. Zinc and alcohol gives off acetylene. — 2. Alcoholic  $AgNO_3$  forms needles of a double compound. — 3. Heated with 50 vols. of water at 150°, it is dissolved in 6 days the products being  $HI$ ,  $C_2H_5Cl$  and chloro-ethylene oxide  $C_2H_4ClO$  (g. v.). — 4. Alcoholic KOH gives off a gas that decomposes in air (chloro- or iodo-acetylene).

**Chloro-iodo-ethylene**  $CH_2=CClI$ . (101°). S.G. 2:2.143. From chloro-bromo-iodo-ethane and alcoholic KOH (Henry, C. R. 98, 741). Oil; turns purple in air and light, absorbing oxygen.

**DI-CHLORO-TETRA-iodo-FLUORESCEN.**

**Hydrate.**  $C_{20}H_{12}Cl_4I_4O_6$ . Formed by adding a solution of iodine in dilute KOH to an alkaline solution of di-chloro-fluorescein and acidifying (Le Royer, A. 238, 359). The alkaline salts are used as dyes ('Rosa Bengale').

**CHLORO-iodo-METHANE**  $CH_3ClI$ . (109°). S.G. 2:2.49. From  $HI$ ,  $CH_3Cl$  and  $I_2$  (Sakurai, C. J. 41, 362).

**Di-chloro-iodo-methane**  $CHCl_2I$ . (131°). S.G. 2:2.454. *Chloroiodoform*. A liquid formed by the action of  $HI$ ,  $Cl$ , or  $PCl_5$  on iodoform (Serullas, A. Ch. [2] 25, 314; 39, 225; Mitscherlich, P. 11, 164; Bouchardat, A. 22, 229; Schlagdenhaufen, J. Ph. [3] 30, 401; Borodin, A. 126, 239).

**Di-chloro-di-iodo-methane**  $CCl_2I_2$ . [85°]. From  $CHI_3$  and  $HgCl_2$  (Borodin, A. 126, 239). From  $CH_2Cl_2$  and  $IBr$  (Böland, A. 240, 234). Glittering scales, with pungent odour. Turned brown by light, alcohol, and ether.

**CHLORO-iodo-METHYL-PYRIDINE**

$C_5H_7ClIN$ . [111°]. *Chloro-iodo-picoline*. From chloro-(α)-picoline, [21°], by digesting with  $I$  and NaOH. Prisms, apparently trimetric (Ost, J. pr. [2] 27, 257).

**CHLORO-iodo-NITRO-BENZENE**

$C_6H_4Cl(NO_2)$  [13:4] [63°]. From the corresponding chloro-nitro-aniline [123°] by displacing  $NH_2$  by  $I$  through the diazo-reaction (Körner, G. 4, 831). Prisms (from ether-alcohol); volatile with steam; sl. sol. cold alcohol.

**Chloro-iodo-nitro-benzene**  $C_6H_4Cl(NO_2)$  [14:3]. [63°]. From chloro-nitro-aniline [116°] by the diazo-reaction (K.). Spherical groups of needles (from hot alcohol).

**CHLORO-iodo-o-oxy-BENZOIC ACID**

$C_6H_3(OH)Cl(CO_2H)$  [2:5:1]. *Chlor-iodo-salicylic acid*. [224°]. Prepared by heating chloro-salicylic acid with iodine and  $HgO$  in alcoholic solution (Smith a. Knerr, Am. 8, 96). Colour-

less needles (from dilute alcohol). V. sl. sol. hot water. Gives a violet colour with  $\text{FeCl}_3$ .

**Salts.**— $\text{NaA}'$  2aq: pink needles; m. sol. water.— $\text{NaA}'$  2aq: flat needles.— $\text{CaA}'$  5aq: pink needles; sol. water.— $\text{MgA}'$  6aq: pink leaflets; sol. hot water.— $\text{ZnA}'$  3aq: white needles; v. sol. hot water.

**Methyl ether**  $\text{MeA}'$ . [130°]. Flat needles.

**Ethyl ether**  $\text{EtA}'$ . White plates. V. sol. hot alcohol.

**TRI-CHLORO-IODO-PHENOL**  $\text{C}_6\text{HCl}_3\text{I(OH)}$ . [80°]. From tri-chloro-ortho-phenol by diazo-reaction (Lampert, *J. pr.* [2] 83, 391). White needles (from alcohol).

**Ethyl derivative**  $\text{C}_6\text{HCl}_3\text{I(OEt)}$ . [61°].

**CHLORO-IODO-PROPANE**  $\text{C}_3\text{H}_4\text{ClI}$  i.e.  $\text{CH}_2\text{CHClCH}_2\text{I}$ . (149°). S.G.  $\frac{1}{4}$  1.933;  $\frac{25}{4}$  1.889. From propylene and aqueous  $\text{ICl}$  (Maxwell Simpson, *Pr.* 12, 278; Friedel & Silva, *A. Ch.* [2] 17, 535). Converted by  $\text{HgCl}_2$  at 100° into propylene chloride.  $\text{HI}$  at 100° gives isopropyl iodide and isopropyl chloride (Sorokin, *J.* 3, 326; Silva, *C. R.* 93, 739). Alcoholic  $\text{KOH}$  gives  $\text{CH}_2\text{CClCH}_2\text{K}$ .

**Chloro-iodo-propane**  $\text{CH}_2\text{CClCH}_2\text{I}$ . *Chloro-iodo-acetol*. (c. 120°) at 10 mm. S.G.  $\frac{1}{4}$  1.821. From  $\text{CH}_2\text{CClCH}_2\text{I}$  and  $\text{HI}$  (Oppenheim, *A. Suppl.* 6, 359). Decomposed by distillation under atmospheric pressure. Moist  $\text{Ag}_2\text{O}$  gives acetone.

**Di-chloro-iodo-propane**  $\text{C}_3\text{H}_2\text{Cl}_2\text{I}$ . *Di-chloro-iodhydrin*. (c. 208°). From  $\text{C}_3\text{H}_4\text{ClI(OH)}$  and  $\text{PCl}_5$  (Henry, *B.* 4, 701).

**CHLORO-IODO-PROPYL ALCOHOL**

$\text{C}_3\text{H}_4\text{ClI(OH)}$ . *Glycerin chloriodhydrin*. (226°). S.G.  $\frac{1}{4}$  2.06. From epiodhydrin and  $\text{HCl}$ ; or from epichlorhydrin and  $\text{HI}$  (Reboul, *A. Suppl.* 1, 225). Conc.  $\text{KOH}$ aq gives epichlorhydrin.

**CHLORO-IODO-PROPYLAMINE**

$\text{C}_3\text{H}_4\text{ClI(NH}_2\text{)}$ . From allylamine hydrochloride and  $\text{ICl}$  (Henry, *B.* 8, 399).— $\text{B}'$   $\text{H}_2\text{PtCl}_6$ .

**CHLORO-IODO-PROPYLENE**  $\text{C}_3\text{H}_3\text{ClI}$  i.e.  $\text{CH}_2\text{CClCH=CH}_2$ . (c. 150°). S.G.  $\frac{1}{4}$  1.913. From di-chloro-propylene and  $\text{CaI}_2$  at 100° (v. Romburgh, *R. T. C.* 1, 233). Combines with mercury. Heated with  $\text{KOH}$  or  $\text{Ag}_2\text{O}$  it yields  $\alpha$ -chloro-allyl alcohol.  $\text{AgNO}_3$  gives  $\alpha$ -chloro-allyl nitrate.

**Chloro-iodo-propylene**  $\text{C}_3\text{H}_3\text{ClI}$  i.e.  $\text{CHClCH=CH}_2$ . (162°). S.G.  $\frac{1}{4}$  1.97. Colourless liquid, with irritating odour and sharp taste. Prepared by heating dry  $\text{CaI}_2$  with  $\text{CHClCH}_2\text{CH}_2\text{Cl}$  at 100°, or by heating dry  $\text{KI}$  or  $\text{CaI}_2$  in excess with allylidene chloride at 100° for 24 hours. Combines with  $\text{Hg}$  forming white plates, very soluble in alcohol. With  $\text{KOH}$  it yields  $\beta$ -chloro-allyl alcohol (P. v. Romburgh, *R. T. C.* 1, 233).

(a) **CHLORO-IODO-TOLUENE**  $\text{C}_7\text{H}_4\text{ClI}$ . (243°). S.G.  $\frac{1}{4}$  1.716. From (a)-chloro-nitro-toluene by reduction and displacement of  $\text{NH}_4$  by  $\text{I}$  through the diazo-reaction (Wroblewsky, *Z.* [2] 6, 164; *A.* 168, 210). Liquid.

(b) **Chloro-iodo-toluene**  $\text{C}_7\text{H}_4\text{ClI}$ . [10°]. (240°). S.G.  $\frac{1}{4}$  1.770. From (b)-chloro-nitro-toluene (W.). **Chloro-iodo-toluene**  $\text{C}_7\text{H}_4\text{ClI}$ . (240°). S.G.  $\frac{1}{4}$  1.702. From chlorinated *o*-toluidine (Beilstein & Kuhlberg, *A.* 168, 82).

**CHLORO-ISATIN** v. **ISATIN**.

**CHLORO-ISATOIC ACID**  $\text{C}_7\text{H}_4\text{ClNO}_2$  i.e.  $\text{C}_6\text{H}_3\text{Cl}(\text{CO})_2\text{CO}_2\text{H}$ . [265°–268°]. From chloro-

isatin (10 g.),  $\text{CrO}_3$  (20 g.), and  $\text{HOAc}$  (120 g.) (Dorsch, *J. pr.* [2] 83, 49). Pearly plates (from alcohol-acetone). Insol. water, ether, and benzene. Boiling conc.  $\text{HCl}$  gives  $\text{CO}_2$  and chloro-*o*-amido-benzoic acid. Ammonia gives  $\text{CO}_2$  and chloro-benzamide.

**Di-chloro-isatoic acid**  $\text{C}_6\text{H}_2\text{Cl}_2(\text{CO})_2\text{CO}_2\text{H}$ .

[256°]. From di-chloro-isatin (10 g.),  $\text{CrO}_3$  (15 g.), and  $\text{HOAc}$  (60 g.) (D.). Yellow prisms (from alcohol-acetone).

**CHLORO-LACTIC ACID** v. **CHLORO-OXY-PROPIONIC ACID**.

**CHLORO-LEVULIC ACID** v. **CHLORO-ACETYL-PROPIONIC ACID**.

**CHLORO-LUTIDINE** v. **CHLORO-DI-METHYL-PYRIDINE**.

**CHLORO-MALEIC ACID**  $\text{C}_4\text{HCl(COOH)}_2$ . [172°]. The acid so called by Perkin and Duppé is probably chloro-fumaric acid (q. v.).

**Formation.**—Among the products of the action of  $\text{ClOH}$  on benzene (Carius, *A.* 142, 139; 155, 217; cf. Kekulé & Strecker, *A.* 223, 183).

**Salts.**— $\text{KHA}'$  aq.— $\text{BaA}'$  5aq. Crusts.

**Anhydride**  $\text{C}_4\text{HCl(CO)}_2\text{O}$ . [0°] and [34.5°]. Formed by heating a mixture of chloro-fumaric acid and its chloride (Perkin, *C. J. Proc.* 4, 76). Dimorphous.

**Di-chloro-maleic acid**  $\text{C}_4\text{Cl}_2(\text{CO}_2\text{H})_2$ .

**Preparation.**—The chloride  $\text{C}_4\text{Cl}_2(\text{C}_2\text{Cl}_2\text{O})$  (see below) warmed with conc.  $\text{H}_2\text{SO}_4$  dissolves with evolution of  $\text{HCl}$ . The crystals which separate (anhydride) are dissolved in water (becoming hydrated), the solution is extracted with ether, and the ethereal extract evaporated and placed over  $\text{H}_2\text{SO}_4$ . Hygroscopic crystals of the acid are formed. On sublimation they split up into  $\text{H}_2\text{O}$  and the anhydride,  $\text{C}_4\text{Cl}_2(\text{CO})_2\text{O}$ . The acid may also be obtained by boiling its imide with potash.

**Properties.**—Hygroscopic crystals. Changes over  $\text{H}_2\text{SO}_4$  into the anhydride. Also by boiling with ligroin (40°), in which the anhydride dissolves, but the acid does not.

**Salt.**— $\text{AgA}'$ . Silky needles. Explodes when heated.

**Methyl ether.**— $\text{MeA}'$ . (225°).

**Anhydride**  $\text{C}_4\text{Cl}_2(\text{CO})_2\text{O}$ . [120°]. Laminæ; may be sublimed. Slowly dissolves in water, changing to the acid.

**Tetrachlorinated derivative of the anhydride**  $\text{C}_4\text{Cl}_6(\text{CO})_2\text{O}$ .

(b) Solid: [41°] (209°). V.D. ( $H=1$ ) 254 (Theory 277). ( $\text{C}_4\text{Cl}_6(\text{CCl}_2)_2\text{O}$ ).

(a) Liquid: (194°–214°). V.D. ( $H=1$ ) 236 ( $\text{C}_4\text{Cl}_6(\text{CCl}_2)_2\text{COCl}$ ).

**Preparation.**—By heating a mixture of  $\text{POCl}_3$  (24 g.), succinyl chloride (8 g.) and  $\text{PCl}_5$  (45 g.) in sealed tubes at 230°. The product is distilled and the fraction 125°–215° is treated with water. The heavy oil which separates is distilled with steam. It is chiefly liquid chloride. To get the solid isomeric, the liquid is heated with  $\text{PCl}_5$  at 250°, the product poured into water and distilled with steam. The oily distillate is dried over  $\text{CaCl}_2$  and distilled. The distillate deposits plates of the solid chloride, which may be recrystallised from alcohol of 90 per cent. (Käuder, *J. pr.* [2] 81, 2, 7).

**Reactions.**—1. Warm conc.  $\text{H}_2\text{SO}_4$  converts both the solid and the liquid chloride into di-

chloro-maleic anhydride.—2. The vapour undergoes dissociation when heated strongly, hence the V.D. is rather low.—3. Water and dilute NaOH have hardly any action on the chlorides. The liquid chloride is readily decomposed by alcoholic NaOH, forming di-chloro-maleic acid.—4. Sodium amalgam reduces it in alcoholic solution to succinic acid, di-chloro-maleic anhydride being also formed.—5. The liquid chloride is violently attacked by ammonia. The solid chloride is not attacked by alcoholic ammonia below 130°. Ethylamine and aniline attack the liquid, but not the solid chloride.—6. Neither chloride is attacked by Cl or Br.—7. PCl<sub>5</sub> at 250° converts the liquid into the solid chloride, but breaks both up thus:

*Imide* C<sub>2</sub>Cl<sub>2</sub>O.NH<sub>2</sub>. Formed by chlorination of succinimide at 150° or by boiling per-chloro-pyrrocoll ortho-bromide with dilute acetic acid (Ciamician a. Silber, B. 16, 2393; 17, 553; G. 14, 31). Trimetric crystals, *a:b:c* = .9922:1:1.5934. V. sol. hot water, alcohol, and ether. Heated with PCl<sub>5</sub> at 200° for 24 hours it is converted into the per-chloride C<sub>2</sub>Cl<sub>4</sub>N, which is reduced by zinc-dust and HCl to tri-chloro-pyrrol. By heating with water it yields (α)-di-chloro-acrylic acid, CO<sub>2</sub>, and NH<sub>3</sub>.

*Perchlorinated imide* C<sub>2</sub>Cl<sub>4</sub>N. [70°–73°]. (144° at 20 mm.). White wax-like solid. V. sol. alcohol, ether, and acetic acid, nearly insol. water. Formed by heating di-chloro-maleimide with PCl<sub>5</sub> at 200° for 24 hours. Zinc-dust and acetic or hydrochloric acid reduce it to tetra-chloro-pyrrol (Ciamician a. Silber, B. 17, 554).

*Phenyl-imide* C<sub>2</sub>Cl<sub>2</sub><CO>NPh. [201°].

Silvery plates. Got by action of PCl<sub>5</sub> on phenyl-succinimide (v. Succinimide). HCl decomposes it into aniline and di-chloro-maleic acid.

**CHLOROMALONIC ACID** C<sub>2</sub>H<sub>2</sub>ClO<sub>4</sub>, i.e. CHCl(CO<sub>2</sub>H)<sub>2</sub>. [133°]. Formed by saponification of the ether by cold alcoholic KOH (Conrad a. Guthzeit, B. 15, 605). Prisms. Sol. water, alcohol, and ether. Heated to 180° it loses CO<sub>2</sub> and gives chloro-acetic acid.—A'Ag: white crystalline pp.

*Diethyl ether* A'Et<sub>2</sub>. [222°]. S.G. 1.185. Prepared by the action of chlorine on malonic ether. On saponification with KOH it gives tartaric acid (Conrad a. Bischoff, B. 13, 600; A. 209, 218). The sodium derivative reacts with [2:1] C<sub>2</sub>H<sub>5</sub>(CH<sub>2</sub>Br)<sub>2</sub> with production of C<sub>2</sub>H<sub>5</sub>(CH<sub>2</sub>CCl(CO<sub>2</sub>Et))<sub>2</sub>, whence alcoholic KOH gives C<sub>2</sub>H<sub>5</sub>(CH(CO<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub>H))<sub>2</sub> (Perkin, C. J. 53, 14).

*Amide* CHCl(CONH<sub>2</sub>)<sub>2</sub>. [170°]. Tables, v. sol. hot water and alcohol.

**CHLORO-MECONIC ACID** v. MECONIC ACID.

**CHLORO-MEYLENE** v. CHLORO-PENTINENE.

**CHLORO-TRIMESIC ACID** C<sub>2</sub>H<sub>2</sub>Cl(CO<sub>2</sub>H)<sub>3</sub>. [278°]. From oxy-trimesic acid and PCl<sub>5</sub> (Ost, J. pr. [2] 15, 303). Needles or tables (from water) (containing aq.)—BaA''', 7aq: m. sol. hot water.

**CHLORO-MESITYLENE** C<sub>6</sub>H<sub>3</sub>Cl(CH<sub>3</sub>)<sub>2</sub>. [205°]. Formed, together with di- and tri-chloro-mesitylene by passing chlorine into cold mesitylene (Fittig a. Hoogewerf, A. 150, 323; Z. [2] 5, 168). Fuming HNO<sub>3</sub> forms a di-nitro-derivative [177°].

**α-Chloro-mesitylene** C<sub>6</sub>H<sub>3</sub>(CH<sub>3</sub>)<sub>2</sub>CH<sub>2</sub>Cl. [215°–220°]. Obtained by chlorinating mesitylene at 215° (Robinet, C. R. 96, 500). NaOAc gives C<sub>6</sub>H<sub>3</sub>(CH<sub>3</sub>)<sub>2</sub>CH<sub>2</sub>OAc. [242°].

**Di-chloro-mesitylene** C<sub>6</sub>H<sub>3</sub>(CH<sub>3</sub>)<sub>2</sub>. [59°]. [244°]. Formed by chlorinating cold mesitylene (F. a. H.). Prisms (from alcohol). Volatile with steam.

**α-Di-chloro-mesitylene** C<sub>6</sub>H<sub>3</sub>(CH<sub>3</sub>)<sub>2</sub>(CH<sub>2</sub>Cl)<sub>2</sub>. [41°]. [260°]. Formed by chlorinating mesitylene at 215° (R.). Needles.

**Tri-chloro-mesitylene** C<sub>6</sub>Cl<sub>3</sub>(CH<sub>3</sub>)<sub>2</sub>. [205°] (F. a. H.); [208°] (Kurbatoff, J. R. 1888 [1] 129). [280°]. From cold mesitylene and excess of Cl (Kane, P. 44, 474; F. a. H.). From o-di-chloro-benzene, AlCl<sub>3</sub>, and MeCl at 100° (Friedel a. Crafts, A. Ch. [6] 10, 411). Slender needles (from alcohol). Not attacked by oxidising agents. HI (S.G. 1.9) heated with it forms mesitylene.

**ω-Tri-chloro-mesitylene** C<sub>6</sub>H<sub>3</sub>(CH<sub>2</sub>Cl)<sub>3</sub>. (c. 280°). Prepared by heating the corresponding alcohol with HCl and fractionating the crude product *in vacuo*. Has not been obtained pure. Heavy oil. Boiled with water and PbCO<sub>3</sub> it regenerates C<sub>6</sub>H<sub>3</sub>(CH<sub>2</sub>OH)<sub>3</sub> (Colson, A. Ch. [6] 6, 97).

#### CHLORO-MESITYLENIC ACID

C<sub>6</sub>H<sub>3</sub>Cl(CH<sub>3</sub>)<sub>2</sub>(CO<sub>2</sub>H) [4:3:5:1]. From chloro-mesitylene and dilute HNO<sub>3</sub> (Fittig a. Hoogewerf, A. 150, 325). Monoclinic prisms (from alcohol). Turns brown above 200° without melting. Sl. sol. boiling water.—BaA', 4aq.—CaA', 5aq: tufts of flattened needles.

**CHLORO-METHACRYLIC ACID** C<sub>2</sub>H<sub>2</sub>ClO<sub>4</sub>. [59°]. From tri-chloro-isobutyric acid, HCl, and zinc-dust (Gottlieb, J. pr. [2] 12, 19). Formed also by heating an aqueous solution of sodium citra-di-chloro-pyrotartrate; or by passing chlorine into an aqueous solution of sodium citraconate (Swarts, J. 1873, 583; Morawski, J. pr. [2] 12, 363; Stz. W. [2] 74, 89). Needles, volatile with steam.

**Salts.**—KA' aq.—AgA'.—CaA', 3aq.—BaA', 4aq.—PbA', aq.—CuA'(OH).

*Ethyl ether* EtA'. [157°].

**Di-chloro-methacrylic acid** C<sub>2</sub>H<sub>2</sub>Cl<sub>2</sub>O<sub>4</sub>. [64°]. [216°]. Formed by the action of alkalis on tri-chloro-isobutyric acid (Gottlieb, J. pr. [2] 12, 8; Morawski, C. C. 1877, 131). Slender prisms; may be sublimed. Attacks the skin. Sodium amalgam forms isobutyric acid.—NaA' aq.—KA' aq.—AgA'.—CaA', 2aq.—PbA', aq. [100°].—CuA'.

**CHLORO-METHANE** v. METHYL CHLORIDE.

**Di-chloro-methane** v. METHYLENE CHLORIDE.

**Tri-chloro-methane** v. CHLOROFORM.

**Tetra-chloro-methane** v. CARBON-TETRA-CHLORIDE, vol. i. p. 688.

**CHLORO-METHANE-TRICARBOXYLIC ETHER** CCl(CO<sub>2</sub>Et)<sub>3</sub>. [210°] at 140 mm. Prepared by chlorination of methane-tricarboxylic ether. By saponification it yields oxy-methane-tricarboxylic acid (carboxytartaric acid) (Conrad, B. 14, 619).

**TRI-CHLORO-METHANE SULPHINIC ACID**

\*CCl<sub>3</sub>.SO<sub>2</sub>H. From tri-chloro-methane sulphochloride and alcoholic KCN or H<sub>2</sub>S (Löw, Z. 1869, 82, 614; Rathke, A. 161, 149). Unstable needles.—Salts.—KA'. Its solution gives with Bra characteristics pp. of CCl<sub>3</sub>.SO<sub>2</sub>Br. Boiling water converts it into HCl(SO<sub>2</sub>K). HNO<sub>3</sub> gives

less needles (from dilute alcohol). V. sl. sol. hot water. Gives a violet colour with  $\text{FeCl}_3$ .

**Salts.**— $\text{NaA}'$  2aq: pink needles; m. sol. water. —  $\text{NaA}'$  2aq: flat needles. —  $\text{CaA}'$  5aq: pink needles; sol. water. —  $\text{MgA}'$  6aq: pink leaflets; sol. hot water. —  $\text{ZnA}'$  3aq: white needles; v. sol. hot water.

**Methyl ether**  $\text{MeA}'$ . [130°]. Flat needles.

**Ethyl ether**  $\text{EtA}'$ . White plates. V. sol. hot alcohol.

**TRI-CHLORO-IODO-PHENOL**  $\text{C}_6\text{HCl}_3\text{I}(\text{OH})$ . [80°]. From tri-chloro-ortho-phenol by diazo-reaction (Lampert, *J. pr.* [2] 83, 391). White needles (from alcohol).

**Ethyl derivative**  $\text{C}_6\text{HCl}_3\text{I}(\text{OEt})$ . [61°].

**CHLORO-IODO-PROPANE**  $\text{C}_3\text{H}_5\text{ClI}$  i.e.  $\text{CH}_3\text{CHClCH}_2\text{I}$ . (149°). S.G.  $\frac{1}{4}$  1.933;  $\frac{25}{4}$  1.889. From propylene and aqueous  $\text{ICl}$  (Maxwell Simpson, *Pr.* 12, 278; Friedel & Silva, *A. Ch.* [2] 17, 535). Converted by  $\text{HgCl}_2$  at 100° into propylene chloride.  $\text{HI}$  at 100° gives isopropyl iodide and isopropyl chloride (Sorokin, *J.* 3, 326; Silva, *C. R.* 93, 739). Alcoholic  $\text{KOH}$  gives  $\text{CH}_3\text{CCl}_2\text{CH}_2\text{I}$ .

**Chloro-iodo-propane**  $\text{CH}_3\text{CClI}_2\text{CH}_3$ . *Chloro-iodo-acetol*. (c. 120°) at 10 mm. S.G.  $\frac{1}{4}$  1.821. From  $\text{CH}_3\text{CCl}_2\text{CH}_3$  and  $\text{HI}$  (Oppenheim, *A. Suppl.* 6, 359). Decomposed by distillation under atmospheric pressure. Moist  $\text{Ag}_2\text{O}$  gives acetone.

**Di-chloro-iodo-propane**  $\text{C}_3\text{H}_4\text{Cl}_2\text{I}$ . *Di-chloro-iodhydrin*. (c. 208°). From  $\text{C}_3\text{H}_5\text{ClI}(\text{OH})$  and  $\text{PCl}_5$  (Henry, *B.* 4, 701).

**CHLORO-IODO-PROPYL ALCOHOL**

$\text{C}_3\text{H}_5\text{ClI}(\text{OH})$ . *Glycerin chloriodhydrin*. (226°). S.G.  $\frac{1}{4}$  2.06. From epiodhydrin and  $\text{HCl}$ ; or from epichlorhydrin and  $\text{HI}$  (Reboul, *A. Suppl.* 1, 225). Conc.  $\text{KOH}$ aq gives epichlorhydrin.

**CHLORO-IODO-PROPYLAMINE**

$\text{C}_3\text{H}_5\text{ClI}(\text{NH}_2)$ . From allylamine hydrochloride and  $\text{ICl}$  (Henry, *B.* 8, 399). —  $\text{B}'\text{H}_2\text{PtCl}_4$ .

**CHLORO-IODO-PROPYLENE**  $\text{C}_3\text{H}_4\text{ClI}$  i.e.  $\text{CH}_2\text{CClCH}_2\text{I}$ . (c. 150°). S.G.  $\frac{1}{4}$  1.913. From di-chloro-propylene and  $\text{CaI}_2$  at 100° (v. Romburgh, *R. T. C.* 1, 233). Combines with mercury. Heated with  $\text{KOH}$  or  $\text{Ag}_2\text{O}$  it yields  $\alpha$ -chloro-allyl alcohol.  $\text{AgNO}_3$  gives  $\alpha$ -chloro-allyl nitrate.

**Chloro-iodo-propylene**  $\text{C}_3\text{H}_4\text{Cl}_2$  i.e.  $\text{CHClCHClCH}_2\text{I}$ . (162°). S.G.  $\frac{1}{4}$  1.97. Colourless liquid, with irritating odour and sharp taste. Prepared by heating dry  $\text{CaI}_2$  with  $\text{CHClCHClCH}_2\text{Cl}$  at 100°, or by heating dry  $\text{KI}$  or  $\text{CaI}_2$  in excess with allylidene chloride at 100° for 24 hours. Combines with  $\text{Hg}$  forming white plates, very soluble in alcohol. With  $\text{KOH}$  it yields  $\beta$ -chloro-allyl alcohol (P. v. Romburgh, *R. T. C.* 1, 233).

(a) **CHLORO-IODO-TOLUENE**  $\text{C}_7\text{H}_5\text{ClI}$ . (243°). S.G.  $\frac{1}{4}$  1.716. From (a)-chloro-nitro-toluene by reduction and displacement of  $\text{NH}_4$  by  $\text{I}$  through the diazo-reaction (Wroblewsky, *Z.* [2] 6, 164; *A.* 168, 210). Liquid.

(b) **Chloro-iodo-toluene**  $\text{C}_7\text{H}_5\text{ClI}$ . [10°]. (240°). S.G.  $\frac{1}{4}$  1.770. From (b)-chloro-nitro-toluene (W.). **Chloro-iodo-toluene**  $\text{C}_7\text{H}_5\text{ClI}$ . (240°). S.G.  $\frac{1}{4}$  1.702. From chlorinated *o*-toluidine (Beilstein & Kuhlberg, *A.* 168, 82).

**CHLORO-ISATIN** v. **ISATIN**.

**CHLORO-ISATOIC ACID**  $\text{C}_7\text{H}_4\text{ClNO}_2$  i.e.  $\text{C}_6\text{H}_3\text{Cl}(\text{CO})_2\text{CO}_2\text{H}$ . [265°–268°]. From chloro-

isatin (10 g.),  $\text{CrO}_3$  (20 g.), and  $\text{HOAc}$  (120 g.) (Dorsch, *J. pr.* [2] 83, 49). Pearly plates (from alcohol-acetone). Insol. water, ether, and benzene. Boiling conc.  $\text{HCl}$  gives  $\text{CO}_2$  and chloro-*o*-amido-benzoic acid. Ammonia gives  $\text{CO}_2$  and chloro-benzamide.

**Di-chloro-isatoic acid**  $\text{C}_6\text{H}_2\text{Cl}_2(\text{CO})_2\text{CO}_2\text{H}$ .

[256°]. From di-chloro-isatin (10 g.),  $\text{CrO}_3$  (15 g.), and  $\text{HOAc}$  (60 g.) (D.). Yellow prisms (from alcohol-acetone).

**CHLORO-LACTIC ACID** v. **CHLORO-OXY-PROPIONIC ACID**.

**CHLORO-LEVULIC ACID** v. **CHLORO-ACETYL-PROPIONIC ACID**.

**CHLORO-LUTIDINE** v. **CHLORO-DI-METHYL-PYRIDINE**.

**CHLORO-MALEIC ACID**  $\text{C}_4\text{HCl}(\text{CO}_2\text{H})_2$ . [172°]. The acid so called by Perkin and Duppé is probably chloro-fumaric acid (q. v.).

**Formation.**—Among the products of the action of  $\text{ClOH}$  on benzene (Carius, *A.* 142, 139; 155, 217; cf. Kekulé & Strecker, *A.* 223, 183).

**Salts.**— $\text{KHA}'$  aq. —  $\text{BaA}'$  5aq. Crusts.

**Anhydride**  $\text{C}_4\text{HCl}(\text{CO})_2\text{O}$ . [0°] and [34.5°]. Formed by heating a mixture of chloro-fumaric acid and its chloride (Perkin, *C. J. Proc.* 4, 76). Dimorphous.

**Di-chloro-maleic acid**  $\text{C}_4\text{Cl}_2(\text{CO}_2\text{H})_2$ .

**Preparation.**—The chloride  $\text{C}_4\text{Cl}_2(\text{C}_2\text{Cl}_2\text{O})$  (see below) warmed with conc.  $\text{H}_2\text{SO}_4$  dissolves with evolution of  $\text{HCl}$ . The crystals which separate (anhydride) are dissolved in water (becoming hydrated), the solution is extracted with ether, and the ethereal extract evaporated and placed over  $\text{H}_2\text{SO}_4$ . Hygroscopic crystals of the acid are formed. On sublimation they split up into  $\text{H}_2\text{O}$  and the anhydride,  $\text{C}_4\text{Cl}_2(\text{CO})_2\text{O}$ . The acid may also be obtained by boiling its imide with potash.

**Properties.**—Hygroscopic crystals. Changes over  $\text{H}_2\text{SO}_4$  into the anhydride. "Also by boiling with ligroin (40°), in which the anhydride dissolves, but the acid does not.

**Salt.**— $\text{AgA}'$ . Silky needles. Explodes when heated.

**Methyl ether.**— $\text{MeA}'$ . (225°).

**Anhydride**  $\text{C}_4\text{Cl}_2(\text{CO})_2\text{O}$ . [120°]. Laminæ; may be sublimed. Slowly dissolves in water, changing to the acid.

**Tetrachlorinated derivative of the anhydride**  $\text{C}_4\text{Cl}_6(\text{CO})_2\text{O}$ .

(b) Solid: [41°] (209°). V.D. ( $H=1$ ) 254 (Theory 277). ( $\text{C}_4\text{Cl}_6(\text{CCl}_2)_2\text{O}$ ).

(a) Liquid: (194°–214°). V.D. ( $H=1$ ) 236 ( $\text{C}_4\text{Cl}_6(\text{CCl}_2)_2\text{COCl}$ ).

**Preparation.**—By heating a mixture of  $\text{POCl}_3$  (24 g.), succinyl chloride (8 g.) and  $\text{PCl}_5$  (45 g.) in sealed tubes at 230°. The product is distilled and the fraction 125°–215° is treated with water. The heavy oil which separates is distilled with steam. It is chiefly liquid chloride. To get the solid isomeric, the liquid is heated with  $\text{PCl}_5$  at 250°, the product poured into water and distilled with steam. The oily distillate is dried over  $\text{CaCl}_2$  and distilled. The distillate deposits plates of the solid chloride, which may be recrystallised from alcohol of 90 per cent. (Käuder, *J. pr.* [2] 81, 2, 7).

**Reactions.**—1. Warm conc.  $\text{H}_2\text{SO}_4$  converts both the solid and the liquid chloride into di-

[116°]: needles, sol. alcohol, HOAc, and ether. On heating with *alkalis* chloroform is split off, and methyl-amido-benzoic aldehyde is formed.

Salt.—B'HCl: thick prisms, v. sol. hot, v. l. sol. cold, water.

Tri-chloro-di-methyl-*p*-amido-phenyl ethyl alcohol  $\text{CCl}_3\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{NMe}_2$ . [111°]. White lates. Obtained by adding 5 pts. of powdered  $\text{m-Cl}_3$  to a cooled mixture of 10 pts. of chloral hydrate and 40 pts. of dimethylaniline, and allowing the mixture to stand at about 50° for 24 ours; yield 7 pts. By boiling with aqueous or alcoholic KOH it is decomposed into chloroform and di-methyl-*p*-amido-benzaldehyde (73°).—HCl. Sparingly soluble colourless needles (Kessneck, *A* 18, 1516).

***p*-CHLORO-TETRA-METHYL-*p*-DI-AMIDO-DI-PHENYL-METHANE**

$\text{H}_2\text{C}(\text{CH}(\text{C}_6\text{H}_4\text{NMe}_2))_2$ . [143°]. Obtained by sating together di-methyl-aniline and *p*-chloro-benzaldehyde in presence of  $\text{ZnCl}_2$  (Kaeswurm, *B* 19, 742). Small colourless concentric needles. ol. benzene, alcohol and ether, sparingly in grain, insol. water. On oxidation it gives the urbinol base which forms colourless crystals (46°), easily sol. benzene and ether, of which the inc double chloride is a bluish-green dyestuff.

Salts.—B'HCl.PtCl<sub>5</sub>: easily sol. yellow crystalline pp. The chloride and sulphate are easily soluble colourless salts.

*Ecto*-Di-chloro- $\alpha$ -methyl-di-amido-di-phenyl-methane  $\text{CCl}_2(\text{C}_6\text{H}_4\text{NMe}_2)_2$ . From  $\text{CS}(\text{C}_6\text{H}_4\text{NMe}_2)_2$  and  $\text{BzCl}$  in  $\text{CS}_2$  (Baither, *B* 20, 3289). Converted by water into the ketone  $\text{CO}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ .

***o*-CHLORO-METHYL-*o*-AMIDO-STYRENE**  
 $\text{H}_2\text{C}(\text{NHMe})\text{CH}(\text{CHCl})$ . Formed by methylation of chloro-amido-styrene (Lipp, *B* 17, 2509). liquid. V. sol. alcohol and ether, nearly insol. water. Volatile with steam. Heated with sodium ethylate at 130°-140° it is converted

***p*-DI-CHLORO-METHYL-AMINE v. METHYL-MINE.**

**CHLORO-METHYL-ANILINE**  $\text{C}_6\text{H}_4\text{ClNMe}$  i.e.  $\text{H}_2\text{C}(\text{Cl})\text{NHMe}$ . (240°). Formed by treating  $\text{Me}(\text{CHO})\text{C}_6\text{H}_4\text{ClCO}_2\text{H}$  with conc. HCl (La Roche a. Bodewig, *B* 18, 430). Liquid.—B'HCl: [164°].

*m*-Chloro-methyl-aniline [3:1]  $\text{C}_6\text{H}_4\text{ClNHMe}$ . *Acetyl derivative*  $\text{C}_6\text{H}_4\text{ClNHMeAc}$ . [93°]. From *m*-chloro-di-methyl-aniline and AcBr (Staedel, *B* 19, 1948). Tables, v.e. sol. benzene.

*p*-Chloro-methyl-aniline *Nitrosamine*.  $\text{H}_2\text{C}(\text{Cl})\text{NHMe.NO}$ . [51°]. From *p*-chloro-di-methyl-aniline and nitrous acid (Koch, *B* 20, 1459).

*o*-Chloro-di-methyl-aniline  $\text{C}_6\text{H}_3\text{Cl}(\text{NMe})_2$  [1:2]. 206°. Formed by heating *o*-chloroaniline hydrobromide (1.5 mol.) with methyl alcohol rather more than 2 mols. for 10 hours at 145°. Colourless fluid. The hydrochloride forms microscopic needles, the ferrocyanide white crystals, insol. water.—B'H<sub>2</sub>Cl<sub>2</sub>PtCl<sub>5</sub> (Heidberg, *B* 20, 149).

*m*-Chloro-di-methyl-aniline [3:1]  $\text{C}_6\text{H}_4\text{ClNMe}_2$ . 232°. From *m*-chloro-aniline hydrobromide (a little over 2 mols.) and MeOH (1 mol.) by heating for 8 hours at 145° (Baur a. Staedel, *B* 16,

32). AcBr decomposes it in the cold, displacing Me by Ac, and forming  $\text{C}_6\text{H}_4\text{ClNMeAc}$  (Staedel, *B* 19, 1948).—B'HBz: red plates.—B'HCi: slender needles.—B'H<sub>2</sub>Cl<sub>2</sub>PtCl<sub>5</sub>: slender yellow needles.

*p*-Chloro-di-methyl-aniline  $\text{C}_6\text{H}_4\text{ClNMe}_2$  [1:4]. [36°]. (230°). Prepared by the action of  $\text{Cu}_2\text{Cl}_2$  upon the diazo compound of *u*-di-methyl-*p*-phenylenediamine. Large flat glistening needles. Sol. alcohol, ether, and benzene, insol. water. The ferrocyanide forms microscopic prisms.—B'H<sub>2</sub>Cl<sub>2</sub>PtCl<sub>5</sub>: golden-yellow prisms (Heidberg, *B* 20, 151).

Di-chloro-di-methyl-aniline  $\text{C}_6\text{H}_3\text{Cl}_2\text{NMe}_2$ . (234°). From dimethylaniline and Cl or SO<sub>2</sub>Cl<sub>2</sub> (Krell, *B* 5, 878; Wenghöfer, *J. pr.* [2] 16, 462). Liquid.—B'H<sub>2</sub>Cl<sub>2</sub>PtCl<sub>5</sub>.

Tri-chloro-di-methyl-aniline  $\text{C}_6\text{H}_3\text{Cl}_3\text{NMe}_2$ . [32°]. (257°). From di-methyl-aniline and Cl (K.).—B'HCi.—B'H<sub>2</sub>Cl<sub>2</sub>PtCl<sub>5</sub>.

**CHLORO-METHYL-BENZENE v. CHLORO-TOLUENE.**

Chloro-di-methyl-benzene v. CHLORO-XYLENE.

Chloro-tri-methyl-benzene v. CHLORO-METHYLENE and CHLORO- $\psi$ -CUMENE.

Chloro-tetra-methyl-benzene v. CHLORO-DURENE.

Hexa-chlor-hexa-methyl-benzene  $\text{C}_6\text{H}_2\text{Cl}_6$ . [269°]. S.G. 1.5 1.609. Probably  $\text{C}_6(\text{CH}_2\text{Cl})_6$ . Formed by the action of  $\text{PCl}_5$  upon  $\text{C}_6(\text{CH}_3)_6$ . Colourless, flattened prisms; commences to sublime at 269°; v. sl. sol. ether, or hot  $\text{CHCl}_3$ . In contact with boiling water, made slightly alkaline, it very slowly loses all its chlorine, giving a body of an alcoholic nature, [180°], v. sl. acids; which is sol. alcohol, sl. sol. ether, v. sl. sol. water (Colson, *Bl.* [2] 46, 197).

Hexa-chlor-hexa-methyl-benzene  $\text{C}_6\text{H}_2\text{Cl}_6$ . [147°].  $\text{C}_6(\text{CCl}_3)(\text{CH}_2\text{Cl})_2(\text{CH}_3)_2$ . Formed together with the preceding symmetrical isomeride by the action of  $\text{PCl}_5$  upon  $\text{C}_6(\text{CH}_3)_6$ . Colourless crystals; sol.  $\text{CHCl}_3$ . Boiling water, slightly alkaline, removes its chlorine. The product is an alcohol-acid, probably  $\text{C}_6(\text{CH}_2\text{OH})_2(\text{CH}_2)_2(\text{CO}_2\text{H})$  (Colson, *Bl.* [2] 46, 198).

**TRI-CHLORO-TRI-METHYL-CARBINYL CHLORIDE v. TETRA-CHLORO-ISOBUTANE.**

**TRI-CHLORO-DI-METHYL CARBONATE**  $\text{CO}(\text{OMe})(\text{OCCl}_3)$ . (91°) at 42 mm. Formed by acting on methyl alcohol with  $\text{ClCO}_2\text{CCl}_3$  (Hentschel, *J. pr.* [2] 36, 314).

Hexa-chloro-di-methyl-carbonate  $\text{CO}(\text{OCCl}_3)_2$ . [79°]. Distils undecomposed. Colourless crystals. Prepared by the action of Cl on methyl carbonate (Councler, *B* 13, 1698).

**CHLORO-METHYL-*pseudo*-CARBO-STYRIL v. CHLORO-OXY-METHYL-QUINOLINE.**

**$\beta$ -CHLORO- $\alpha$ -METHYL-CROTONIC ACID**  
 $\text{CH}_3\text{CCl}:\text{CMe.CO}_2\text{H}$ . (69-6°). Solidifies at 65° (210°). From methyl-aceto-acetic ether and  $\text{PCl}_5$  (Isbert, *A* 234, 188). Laminæ (from hot water).

Salts.— $\text{MgA}^+$ , 2aq.— $\text{ZnA}^+$  1½aq.

Reactions.—1. NaOEt forms the ethyl derivative of  $\beta$ -oxy- $\alpha$ -methyl-crotonic acid.—2. Conc. KOHAq forms methyl ethyl ketone and  $\text{CO}_2$ ; chloro-butylene is not formed as Demarcay asserts.

Ethyl ether EtA'. (173°).

**FER-CHLORO-TRI-METHYL-CYANIDINE**

v. Paranitride of Tri-CHLORO-ACETIC ACID

**CHLORO-TRIMETHYLENE GLYCOL** v. GLYCERIN (8)-CHLORHYDRIN.

**CHLORO-METHYL ETHER** v. CHLORO-DI-METHYL OXIDE.

**CHLORO-METHYL-ETHYL-GLYOXALINE**  $C_2H_4ClN_2$ . *Chloro-oxal-ethylene*. (218°). S.G. 1.142. From either di-ethyl-oxamide by  $PCl_5$  (Wallach, A. 184, 37; 214, 261). Symmetrical di-ethyl-oxamide gives a good yield, the unsymmetrical a bad yield.  $CONEt.HCONEtH$  gives, doubtless,  $NEt.CCl.CCl.NEt$  as intermediate product.  $CONEt.CONH_2$  should give  $CCl.NEt.CO.N$  as intermediate product, but this then changes to  $CCl.NEt.CCl.NEt$  by intra-molecular change. This view is supported by the production of chloro-oxal-ethylene by the action of  $PCl_5$  on di-ethyl-cxamo-nitrile,  $NEt_2.CO.N$ .

*Properties*.—Liquid, with narcotic odour, v. e. sol. alcohol, ether, ligroin, and  $CHCl_3$ . Changed by frequent distillation into an isomeric modification (220°–224°), insol. ligroin. Water at 290° decomposes it, giving  $NH_3$  and  $NH_4Et$ .

*Reactions*.—1. Br in  $CS_2$  or  $CHCl_3$  forms  $B'HBBr$ ,  $C_2H_4BrClN.Br.HBr$  [113°], forming red needles, and  $C_2H_4BrClN.Br_2$  [133°]. Both bodies are unstable, and give, when boiled with water, chloro-bromo-oxal-ethylene. — 2.  $KMnO_4$  gives oxalic acid. — 3. Dilute  $H_2SO_4$  at 240° forms  $NH_3$  and  $NEtH_2$ . — 4. Conc.  $H_2SO_4$  at 220° gives acetic acid. — 5. Distilled over lime it forms para-oxal-methylene. — 6. Na added to its solution in light petroleum forms di-oxal-ethylene,  $C_2H_4N_2$ . — 7. P and HI at 170° reduces it to oxal-ethylene.

*Salts*.— $B'H_2.PtCl_6$ .— $B'HI$  aq.— $B'H_2.ZnCl_2$ .  $B'HBBr$ .— $B'HCIN$  aq.— $B'HgCl_2$ .— $B'4HgCl_2$ .— $B'I_2$  [110°].— $B'AgNO_3$ .— $B'HC_2O_4$ .

*Methylo-iodide*  $B'MeI$ : [205°]; needles (from alcohol).

**CHLORO-METHYL-TRI-ETHYL-PHOSPHONIUM CHLORIDE**  $CH_3Cl.PEt_3Cl$ . From methylene chloride and  $PEt_3$  (Hofmann, *Pr.* 11, 290);  $CH_3(PEt_3Cl)_2$  being formed at the same time. Formed also by the action of water on the compound of  $PEt_3$  and  $CCl_4$ .— $(CH_3Cl.PEt_3Cl)_2.PtCl_6$ . Slightly soluble needles.

**CHLORO-METHYL-GLYOXALINE**  $C_2H_4ClN_2$ . *Chloro-oxal-methylene*. (205°). V.D. 4.1 (obs.). S.G. 1.247.

*Preparation*.—Pure di-methyl-oxamide (10 pts.) is mixed with  $PCl_5$  (83 pts.) in the cold. On warming  $HCl$  is evolved. The product is distilled under diminished pressure, and afterwards with steam, and is finally extracted by shaking with  $CHCl_3$  (Wallach, B. 14, 422; A. 214, 308).

*Properties*.—Liquid; reduced by HI to methyl-glyoxaline.

*Salts*.— $B'H_2.PtCl_6$ .

**CHLORO-METHYL-GLYOXIM** v. CHLORO-1,2-DINITROSO-ACETONE OXIM.

**DI-CHLORO-METHYL-INDOLE**

$C_8H_7\langle\begin{smallmatrix} C(Cl) \\ N(CH_3) \end{smallmatrix}\rangle CCl$  [59°]. Long needles. Insol. alkalis. Formed by methylation of chloro-oxindole-chloride (Baeyer, B. 15, 756).

**CHLORO-METHYL-(PSEUDO)-ISATIN**

$C_8H_7\langle\begin{smallmatrix} CO \\ NMe \end{smallmatrix}\rangle CO$ . [191°]. Long fine red needles. Sublimable. Formed, together with

the formyl derivative of chloro-methyl-amido-benzoic acid, by oxidation of the methyl-chloride of (B. 1or3)-chloro-quinoline with  $KMnO_4$  (La Coste a. Bodewig, B. 18, 429).

**TETRA-CHLORO-DI-METHYLE-DI-KETONE** (?)  $CHCl_2.CO.CO.CHCl_2$  [84°]. (202°). A product of the action of  $KClO_4$  and  $HCl$  on chloranilic acid (Levy a. Jedlicka, B. 21, 318). Large yellow fables (from ether). Pungent; sol. water. Forms a phenyl-hydrazido [186°];

**PER-CHLORO-METHYL-MERCAPTAN**  $CCl_3.SCl$  (?). *Tri-chloro-methyl-sulphur chloride*. *Thiocarbonyl tetrachloride*. (149° uncor.). S.G. 1.722 at 0°; 1.7019 at 11°; 1.6953 at 17½°.

*Formation*.—1. From methyl sulphocyanide and dry chlorine; the yield is 83 p.c. of the sulphocyanide (James, C. J. 51, 272).—2. From  $CS_2$  and chlorine (Rathke, A. 167, 180).—3. From  $CSCl_2$  and  $Cl_2$ .

*Preparation*.—By passing chlorine (5 mols.) into cooled dry  $CS_2$  (1 mol.) containing a trace of iodine; the product is freed from chloride of sulphur by treatment with water and distillation with steam, and is then fractionated *in vacuo*.

*Properties*.—Yellow oil, of very unpleasant strong smell. By long heating to its boiling-point it slowly decomposes, probably into  $CCl_4$  and S.

*Reactions*.—1. By treatment with chlorine in presence of iodine it yields  $CCl_4$  and  $S_2Cl_2$ .—2. *Alcohol* forms an oil, possibly  $CS_2Cl_2$ , and crystals of  $C_2H_4O_2$  (126°).—3. *Water* at 160° splits it up into  $CO_2$ ,  $HCl$ , and S. *Alkalis* act in the same way.—4. By heating with sulphur at 150°–160° it yields  $CS_2$ ,  $CCl_4$ ,  $CSCl_2$ , per-chloro-methyl tri-sulphide  $(CCl_3)_3S_2$ , and per-chloro-methyl di-sulphide  $(CCl_3)_2S_2$ , but the latter appears to be the primary product:  $2CCl_3.SCl + S_2 = (CCl_3)_2S_2 + S_2Cl_2$ . Per-chloro-methyl di-sulphide is also formed by heating per-chloro-methyl mercaptan with silver-powder, thus:  $2CCl_3.SCl + Ag_2 = (CCl_3)_2S_2 + 2AgCl$  (Klason, B. 20, 2376).—5. By  $SnCl_4$  it is reduced to  $CSCl_2$ .—6.  $HNO_3$  (S.G. 1.2) oxidises it to  $CCl_3.SO_2.Cl$ .—7.  $K_2SO_4$  gives  $C(SH)(SO_2.Cl)$ .—8. *Aniline* (2 mols.) forms  $CCl_3.S.NHPh$ ; an unstable oil converted by excess of aniline into di-amid-di-phenyl sulphide, di-phenyl-thio-urea, and tri-phenyl-guanidine; and converted by alcoholic  $KOH$  into  $CCl_3.S.NPh$  (?) [140°] (Rathke, A. 167, 211; B. 19, 395).—9. The analogous compound  $CCl_3.S.NHC_2H_5(CH_3)$  is formed by adding (2 mols. of) p-toluidine to its ethereal solution. This body is crystalline, and by boiling with alcohol it is decomposed into p-toluidine,  $CO$ , and  $H_2S$ ; alcoholic  $KOH$  splits off  $HCl$ , giving a body [138°], which probably has the constitution  $CCl_3.S.N.C_2H_5Me$  (Rathke, B. 19, 895).

**HEXA-CHLORO-METHYL-METHYLENE-DI-KETONE**  $(CCl_3.CO)_2CH_2$ ; (258°). (c. 192°) at 20 mm. Is the final substitution product obtained by the prolonged action of chlorine upon acetyl-acetone at 120°–130°, and in direct sunlight. Colourless liquid, decomposes when distilled under ordinary pressure. Treated with  $NaOH$  (1 mol.) it gives tri-chloro-acetone and sodium tri-chloro-acetate (Combs, A. Ch. [6] 12, 238).

**ω-CHLORO-(8)-METHYL-NAPHTHALENE**  $C_{10}H_7.CH_2Cl$  [47°]. (108° at 30 mm.). White

plating plates. Formed by passing chlorine into (β)-methyl-naphthalene heated to about 160° (Schulze, B. 17, 1529).

**CHLORO-DI-METHYL OXIDE**  $C_2H_4Cl_2O$  i.e.  $CH_3Cl.O.CH_3$ . (60°). From di-methyl oxide and Cl in daylight (Friedel, B. 2] 23, 161; 28, 171; J. R. 84, 247; Kleber, A. 246, 97). Decomposed by water into HCl, MeOH, and formic paraldehyde (trioxymethylene). Ammonia forms hexamethyleneamine. KOAc gives  $CH_3.O.CH_3.OAc$  (118°); which is decomposed by water.

**Di-chloro-di-methyl oxide**  $(CH_3Cl)_2O$ . (105°). V.D. 3.9 (calc. 4.0). S.G. 2 1.318. From  $Me_2O$  and Cl in daylight (Regnault, A. 34, 31; A. Ch. [2] 71, 398). Decomposed by boiling water into HCl, formic acid, and formic paraldehyde (Butlerow, Z. 1855, 618).

**Tetra-chloro-di-methyl oxide**  $(CHCl_2)_2O$ . (130°). V.D. 6.4 (calc. 6.5). S.G. 2 1.606. From  $Me_2O$  and Cl (Regnault, A. Ch. [2] 71, 396).

**Hexa-chloro-di-methyl oxide**  $(CCl_3)_2O$ . (100°). S.G. 1.597. From  $Me_2O$  and Cl in sunshine (Regnault). Decomposed on vaporisation, the V.D. being only 4.67.

**Tri-CHLORO-METHYL-PARACONIC ACID**

v. **Tri-CHLORO-OXY-ETHYL-SUCCINIC ACID**.  
**DI-CHLORO-DI-METHYL-p-PHENYLENE-DIAMINE**  $C_6H_4Cl_2(NMe_2)(NH_2)$  [5:2:4:1]. Formed, together with di-methyl-p-phenylene diamine and di-chloro-p-phenylene-diamine by boiling nitroso-di-methyl-aniline with HCl (1:2 S.G.). By  $K_2Cr_2O_7$  and  $H_2SO_4$  it is oxidised to di-chloro-quinone [159°]. By treatment with  $FeCl_3$  in presence of  $H_2S$  and  $ZnCl_2$  it yields di-chloro-methylene blue (Möhlau, B. 19, 2010).

**CHLORO-METHYL ISOPROPYL KETONE**  $C_6H_4ClO$  i.e.  $CH_3Cl.CO.Pr.$  (c. 120°). From petroleum pentane (?) or inactive amyl chloride by treatment with  $CrO_2Cl_2$  followed by water (Etard, C. R. 84, 127). Insol. water and aqueous KOH; reduces ammoniacal  $AgNO_3$ . Does not combine with  $NaHSO_4$ .

**TRI-CHLORO-METHYL-PURIN**

$C_6(CH_2Cl)_3N$  i.e.  $\begin{matrix} NCl.C.N \\ | \\ CCl.N.C.NMe \end{matrix} \begin{matrix} NCl.C.N \\ | \\ CCl \end{matrix} (?)$  [174°].

Small colourless crystals. Insol. alkalis. Formed by heating di-chloro-oxy-methyl-purin with  $PCl_5$  and  $POCl_3$  at 160° for eight hours. Heated with alcoholic NaOH it yields chloro-di-ethoxy-methyl-purin, which by HCl at 130° is converted into methyl-uric acid (Fischer, B. 17, 331, 1787).

**CHLORO-α-METHYL-PYRIDINE**  $C_6H_5ClN$ . **Chloro-(α)-picoline**. (21°) (165° uncor.). S.G. 2 1.146. Formed by reducing the mixture of penta- and hexachloro-picolines obtained by heating comenamic acid with  $PCl_5$ . The mixture is heated at 240° with a solution of HI in glacial acetic acid (Ost, J. pr. [2] 27, 278).

**Properties**.—Colourless prisms. Smells like pyridine. Nearly insoluble in water, insoluble in potash, soluble in alcohol and in ether.

**Salts**.— $B'H_2Cl$ . Prisms.— $\{B'HCl\}_2PtCl_4$ . Needles or prisms.

**Chloro-methyl-pyridine**  $C_6H_5ClN$ . (160°–170°). From potassium methyl-pyrrol and  $HCl$  (Ciamician a. Dennstedt, B. 14, 1162).— $B'H_2PtCl_4$ .

VOL. II.

**Hexa-chloro-methyl-pyridine**  $C_6HCl_5N(CCl_3)$ . [60°]. The chief product of the action of  $PCl_5$  (7 mols.) on comenamic (di-oxy-pyridine carboxylic acid at 290° (Ost, J. pr. [2] 27, 277). May be distilled with steam.

**Properties**.—Large oblique prisms, or plates (from alcohol). Insol. water, acids and bases.

**Chloro-di-methyl-pyridine**

$MeC-N-CMe$

$HC.CCl_3.CH$ . **Chloro-lutidine**. (178°). S.G. 1.105 at 17°.

Formed by heating oxy-di-methyl-pyridine (leitidone) with  $PCl_5$  at 140°; the yield is 50 p.c. Colourless oil. Sl. sol. water.

**Salts**.—The hydrochloride forms slender needles.— $B'H_2Cl.PtCl_4$ : orange crystalline pp.— $B'H_2Cl.HgCl_2$ : [155°], sl. sol. water. Chloro-di-methyl-pyridine suspended in water gives characteristic pps. with picric acid  $K_2Cr_2O_7$ ,  $CuSO_4$ , and  $AgNO_3$  (Conrad a. Epstein, B. 20, 161).

**Tri-chloro-di-methyl-pyridine**  $C_6H_2Cl_3N$ . Formed by chlorinating (β)-lutidine in presence of iodine (Greville Williams, C. N. 44, 308).— $B'H_2PtCl_4$ .

**CHLORO-DIMETHYL-PYRIDINE CARBOXYLIC ACID**

$MeC-N-CMe$

$HO_2C.C=C(Cl)C.CO_2H$ . **Chloro-lutidine-di-carboxylic acid**. [c. 224°].

Formed by the action of  $PCl_5$  upon oxy-di-methyl-pyridine-di-carboxylic acid (lutidone-di-carboxylic acid) at 140°. White prisms. Sol. hot water (Conrad a. Epstein, B. 20, 164).

**Penta-chloro-tri-methyl-pyridine-di-carboxylic ether**. **Di-chloride**. [150°]. From hydro-tri-methyl-pyridine-di-carboxylic ether by chlorination (Hantzsch, A. 215, 19). Woolly needles (from alcohol).

(Py. 3)-**CHLORO-(Py. 1)-METHYL-QUINO-**

**LINE**  $C_{10}H_7NCl$  i.e.  $O_6H_4 \begin{matrix} CMe:CH \\ | \\ N:CCl \end{matrix}$  [59°].

(296° cor.). From (Py. 3)-oxy-(Py. 1)-methyl-quinoline and  $PCl_5$  (Knorr, A. 236, 97). Mass of slender needles (from dilute alcohol); v. sl. sol. water, v. sol. alcohol and ether; volatile with steam.— $B'H_2PtCl_4$  2aq. Reduced by HI to (Py. 1)-methyl-quinoline. Water at 160° has no action: at 200° it converts it into oxy-methyl-quinoline.

(Py. 2)-**Chloro-(Py. 4)-methyl-quinoline**

$C_6H_4MeClN$  i.e.  $O_6H_4 \begin{matrix} CMe:CCl \\ | \\ N:CH \end{matrix}$  [54°]. From

skatole, chloroform, and alcoholic NaOH (Magnani, G. 17, 252). Delicate needles. Its picric acid compound melts at 208°, and its aurochloride at 164°.

**Chloro-methyl-quinoline**  $C_6H_4MeClN$  i.e.

$O_6H_4 \begin{matrix} CH:CCl \\ | \\ N:CMc \end{matrix}$  [71°]. From methyl-ketole,

chloroform, and alcoholic NaOH, thus:

$C_6H_4MeN + 2NaOH + CHCl_3$   
 $= C_6H_4MeClN + 2NaCl + 2H_2O$

(Magnani, G. 17, 249). White needles, insol. water, sol. alcohol and ether. The picric acid compound forms pale yellow needles [223°].

G

## (Py 1)-Chloro-(Py 3)-methyl-quinoline

$C_6H_4MeClN$  i.e.  $C_6H_4$   $\begin{matrix} \diagup CCl:CH \\ \diagdown N:CMc \end{matrix}$  . (7)-Chloro-quinaldine. [43°]. (270°). From  $PCl_5$  and oxy-methyl-quinoline, the product of condensation of aceto-acetic ether with aniline (Conrad a. Limpach, B. 20, 944). Water at 220° gives oxy-methyl-quinoline. HI in HOAc at 260° gives methyl-quinoline. The picric acid compound melts at 178°.  $B'_2H_4.PtCl_4$ .  $B'HBr$ .  
 (B. 4)-Chloro-(B. 1)-methyl-quinoline

$C_6H_4MeClN$  i.e.  $CH:CMc.C:CH:CH$  [49°].  
 $SH:CCl.C:N:CH$

From (6, 8, 1)-chloro-*m*-toluidine, nitro-benzene, glycerin, and  $H_2SO_4$  (Gattermann a. Kaiser, B. 18, 2603). Needles; v. sol. alcohol, ether, and benzene. HI in HOAc converts it at 250° into (B. 1)-methyl-quinoline. The picric acid compound melts at 172°.  $B'HCl.HgCl_2$ .  $B'_2H_4.FeCl_3$ .

## (Py 3)-Chloro-(Py 2,3)-di-methyl-quinoline

$C_6H_4$   $\begin{matrix} \diagup CMc:CMc \\ \diagdown N:CCl \end{matrix}$  . [131°]. From oxy-di-methyl-quinoline and  $PCl_5$  (Knorr, A. 245, 360). Crystals (from alcohol). Water at 200° forms again the di-methyl-carbostyryl.  $B'_2H_4.PtCl_4$  4aq.

(Py. 1)-Chloro-(Py. 3; B. 2,4)-tri-methyl-quinoline  $C_6H_4.NClMe$ . *o-p*-Di-methyl- $\gamma$ -chloro-quinaldine. [114°]. (298°). Formed by the action of  $PCl_5$  in presence of  $POCl_3$  on (Py. 1,3; B. 2,4)-Oxy-tri-methyl-quinoline (Conrad a. Limpach, B. 21, 527). Flat prisms (from ether). Sublimes easily. Almost insol. water, v. sol. dilute acids, alcohol, ether, and benzene. On heating with aniline the chlorine is replaced by  $NHPh$ .  $B'HCl$ .  $PtCl_4$ ; Needles; v. sl. sol. hot water.

## Di-chloro-(Py. 3)-methyl-quinoline

$C_6H_4Cl_2$   $\begin{matrix} \diagup CH:CH \\ \diagdown N:CMc \end{matrix}$  . Di-chloro-quinaldine. [46°]. (300°). Obtained by heating di-chloro-*o*-amido-benzaldehyde with sodium acetate and aqueous  $NaOH$  (Gnehm, B. 17, 755).

## Di-chloro-(B. 1)-methyl-quinoline

$C_6H_4.NMeCl_2$ . [275°]. Formed by dissolving (B. 1)-methyl-quinoline in boric acid and treating this with a solution of bleaching powder (Einhorn a. Lanch, A. 243, 361). Needles (from acetic ether).

## (Py. 1,2,3)-Tri-chloro-(B. 4)-methyl-quinoline

$C_6H_4(CH_3)$   $\begin{matrix} \diagup CCl:CCl \\ \diagdown N:CCl \end{matrix}$  . Tri-chloro-toluquinoline.

[112°]. Formed by heating (Py. 2,3,1)-di-chloro-oxy-(B. 4)-methyl-quinoline with  $PCl_5$  at 125°. Long colourless needles. Very volatile with steam. Peculiar smell (Righeimer a. Hoffmann, B. 18, 2985).

## (Py. 1,2,3)-Tri-chloro-(B. 2)-methyl-quinoline

$C_6H_4(CH_3)$   $\begin{matrix} \diagup CCl:CCl \\ \diagdown N:CCl \end{matrix}$  . Tri-chloro-toluquinoline.

[184°]. Formation.—1. By the action of  $PCl_5$  upon malon-phenyl-amio acid.—2. The acid malonate of *p*-toluidine (5 g.) is covered with benzene (50 g.) and  $PCl_5$  (25 g.) slowly added; after standing for some time the reaction is completed by heating to boiling.

**Properties.**—Long colourless needles. Sol. alcohol, ether, benzene, etc., insol. water. Volatile with steam. Peculiar smell. Weak base (Righeimer a. Hoffmann, B. 17, 740; 18, 2975, 2979).

## (Py. 2,4,1)-DI-CHLORO-2-METHYL-ISO-

QUINOLINE  $C_6H_4$   $\begin{matrix} \diagup CMc=CCl \\ \diagdown CCl=N \end{matrix}$  . [102°]. Formed by the action of  $POCl_3$  upon the imide\* of phenyl-methyl-acetic-*o*-carboxylic acid  $C_6H_4$   $\begin{matrix} \diagup CHMe.CO \\ \diagdown CO-NH \end{matrix}$  . Long flat needles (Gabriel, B. 20, 2504).

## DI-CHLORO-DI-METHYL-SUCCINIC ACID

$C_6H_4Cl_2O$  i.e.  $CO_2H.CClMe.CClMe.CO_2H$ . Di-chloro-adipic acid. [185°]. Formed, together with pyrocinchonic acid, by the action of 'molecular' silver upon *o*-di-chloro-propionic acid in benzene solution (Otto a. Beckurts, B. 18, 847). Small crystals. Sublimable. V. sol. water and alcohol, v. sl. sol. benzene.

**Reactions.**—By further action of 'molecular' silver it is converted into pyrocinchonic acid  $CO_2H.CMe.CMe.CO_2H$ . On reduction it gives as chief product di-methyl-succinic acid  $CO_2H.CHMe.CHMe.CO_2H$  [194°]. By the action of alcoholic  $KOH$ , or by heating the silver salt with water, chlorotiglic acid  $C_6H_4Cl(CO_2H)$  is formed of melting-point [69°].

Salts.— $A''Na_2$ ; plates.— $A''K_2$  2aq; plates.— $A''Ag_2$ ; white crystalline pp.

## PER-CHLORO-METHYL-DI-SULPHIDE

$(CCl_3)_2S_2$  (135° in *vacuo*). Obtained by the action of silver-powder upon per-chloro-methyl-mercaptan:  $2 CCl_3.SCl + Ag_2 = (CCl_3)_2S_2 + 2 AgCl$ . Also formed by heating per-chloro-methyl-mercaptan with sulphur. Thick yellowish oil, of slight turpentine-like smell. By distillation at the ordinary pressure it decomposes into  $CCl_3.SCl$ ,  $CCl_3Cl$ , and other products. By heating with sulphur at about 170° it yields per-chloro-methyl tri-sulphide  $(CCl_3)_3S_3$  (Klason, B. 20, 2379).

Per-chloro-methyl-tri-sulphide  $(CCl_3)_3S_3$  [57°]. (190° in *vacuo*). Formed by heating per-chloro-methyl di-sulphide with sulphur at 170° (Klason, B. 20, 2380); or by passing chlorine into  $CS_2$  containing iodine (Rathke, A. 167, 209). Flat prisms; v. e. sol. ether,  $CS_2$ , and warm alcohol. On distillation at the ordinary temperature it decomposes into  $CCl_3.SCl$ ,  $CCl_3Cl$ , S, and other products.

## TRI-CHLORO-METHYL-SULPHUR-CHLORIDE v. PER-CHLORO-METHYL-MERCAPTAN.

## CHLORO-METHYL-UREA.

Acetyl derivative  $C_6H_4Cl.NH.CO.NH.CO.CHCl$  i.e.  $CH_2Cl.NH.CO.NH.CO.CHCl$ . [180°]. From chloro-acetamide, Br, and aqueous  $KOH$  (Hofmann, B. 18, 2735). Decomposed by acids and alkalis into formic aldehyde and chloro-acetic acid.

## CHLORO-MUCONIC ACID v. MUCONIC ACID.

(d)-CHLORO-NAPHTHALENE  $C_{10}H_7Cl$  i.e.

$C_{10}H_7$   $\begin{matrix} \diagup CCl:CH \\ \diagdown CH:CH \end{matrix}$  . (261°) (F. a. S.); (268°) (Atterberg, Bl. [2] 28, 509). S.G. 1.20 (O.).

**Formation.**—1. By heating (a)-diazonaphthalene with a large excess of  $HCl$ ; the yield is

88 p.c. of the theoretical (Gasiorowski a. Wajss, *B. 18*, 1939).—2. By boiling naphthalene dichloride  $C_{10}H_6Cl_2$  with alcoholic KOH (Laurent, *A. 8*, 13; Faust a. Saame, *A. 160*, 68; *Z. 2* 5, 705).—3. By the action of  $PCl_5$  on (a)-nitro-naphthalene (De Koninck a. Marquart, *B. 5*, 21) or on naphthalene (a)-sulphonic acid (Carius, *A. 114*, 145). 4. From (a)-nitro-naphthalene and Cl (Atterberg, *B. 9*, 317, 927).

**Preparation.**—By chlorinating naphthalene, washing with alcoholic potash, and fractionating (Roux, *Bl. 2* 45, 515).

**Properties.**—Liquid, not solid at  $-17^\circ$ . In  $CS_2$  solution it is not much acted upon by  $Al_2Cl_6$ , but if (a)-chloro-naphthalene is warmed with 20 p.c. of its weight of  $Al_2Cl_6$ , some naphthalene and tarry matters are produced together with the (β)-compound. In this reaction, therefore, it behaves in a similar manner to (a)-bromonaphthalene. Picric acid compound [137°].

**Formation.**—1. By heating (β)-diazonaphthalene with a large excess of HCl; the yield is 45 p.c. of the theoretical (Gasiorowski a. Wajss, *B. 18*, 1940; cf. Liebermann a. Palm, *A. 183*, 270).—2. By the action of  $PCl_5$  on (β)-naphthol or on naphthalene (β)-sulphonic acid (Kumarenko, *B. 9*, 603; Clève, *Bl. 2* 25, 257).—3. From  $Hg(C_2H_5)_2$  and  $SOCl_2$  (Heumann a. Köchlin, *B. 16*, 1627).—4. By intra-molecular change from (a)-chloro-naphthalene (q.v.).

(1,2)-Di-chloro-naphthalene  $C_{10}H_6Cl_2$  [12] [35°]. Formed by dropping a solution of potassium nitrite (4 g.) in water (20 c.c.) into a boiling solution of (a)-chloro-(β)-naphthylamine hydrochloride (10 g.) and cuprous chloride (5 g.) in hydrochloric acid; yield—4 g. Also from (a)-chloro-(β)-naphthol and  $PCl_5$  and from chloro-(a)-naphthylamine (obtained by reduction of di-chloro-a-naphthylamine) by replacing  $NH_2$  by Cl. Monosymmetric tables,  $a:b:c = 1.5196:1:?$ ,  $B = 76^\circ 46'$  (Clève, *B. 20*, 1991). On nitration it yields di-chloro-di-nitro-naphthalene [170°].  $CrO_3$  forms di-chloro-naphthoquinone [181°].

(γ)- or (1,3)-Di-chloro-naphthalene  $C_{10}H_6Cl_2$  [48°]. From naphthalene (β)-sulphonic acid by nitration and treatment of the resulting (β)-nitro-naphthalene (β)-sulphonic acid with  $PCl_5$  (Clève, *Bl. 2* 29, 499). Also from (β)-naphthylamine (γ)-sulphonic acid by exchanging  $NH_2$  for Cl and treating the product with  $PCl_5$  (Forsling, *B. 20*, 2105). Also from (β')-naphthalene-di-sulphonic acid and  $PCl_5$  (Armstrong a. Wynne); and synthetically from methyl-phenyl-isocrotonic acid (Erdmann a. Kirchhoff). Oxidation by  $HNO_3$  gives chloro-phthalic acid and nitro-phthalic acids.

(δ) or (1,3)-Di-chloro-naphthalene

**Formation.**—1. From (β)-nitro-naphthalene (β)-sulphonic acid and  $PCl_5$  (Clève, *Bl. 2* 29, 415).—2. From di-chloro-(a)-naphthylamine [82°] by the diazo reaction.

**Properties.**—Flat glistening plates, or slender white needles; may be sublimed. By  $HNO_3$  it is oxidised to phthalic acid (Clève, *B. 20*, 449). The so-called 'α'-di-chloro-naphthalene [38°] is

a mixture of the θ and 'β' isomerides. It gives a sulphochloride [148°].

Di-chloro-naphthalene  $C_{10}H_6Cl_2$  [1.2]. [64°].

**Formation.**—1. From β-chloro-naphthalene sulphonic acid and  $PCl_5$  (Arnell, *Bl. 2* 45, 184; Armstrong a. Wynne, *C. J. Proc. 4*, 106).—2. From (β)-naphthol-(a')-sulphonic acid (Bayes's acid) by heating with  $PCl_5$  (Claus a. Volz, *B. 18*, 3157).—3. From (β)-naphthylamine-(a')-sulphonic acid (Badische acid) (Korsling).—4. From chloro-β-naphthol [101°] and  $PCl_5$  (C. a. V.).—5. From p-chloro-phenyl-paraconic acid (Erdmann a. Kirchhoff, *A. 247*, 379).

It gives a sulphochloride [119°].

(β') or (1,4)-Di-chloro-naphthalene

**Formation.**—1. By distillation of naphthalene tetrachloride (Krafft a. Becker, *B. 9*, 1089; Faust a. Saame, *A. 160*, 70).—2. From naphthalene and  $Cl_2O$  (Hermann, *A. 151*, 63).—3. From (a)-chloro-naphthalene in  $CHCl_3$  and Cl (Widmann, *Bn. II*, 139).—4. By the action of  $PCl_5$  on (a)-nitro-(a)-naphthol (Atterberg, *B. 9*, 1189), on bromo-naphthalene sulphonic acid (Jolin, *Bl. 2* 28, 516), or on chloro-naphthalene sulphonic acid, obtained from (a)-naphthylamine-p-sulphonic acid (Clève, *Bl. 2* 26, 242).

**Properties.**—Needles (from alcohol). Boiling dilute  $HNO_3$  forms di-chloro-phthalic acid.  $CrO_3$  in  $HOAc$  gives di-chloro-naphthoquinone [174°].

(ε) or Peri-Di-chloro-naphthalene  $C_{10}H_6Cl_2$ ,

Formed in small quantity on distilling 'β'-di-nitro-naphthalene with  $PCl_5$  (Atterberg, *B. 9*, 1732). Formed also by nitrating (γ)-di-chloro-naphthalene, reducing this to chloro-naphthylamine [91°] and displacing  $NH_2$  by Cl (Atterberg, *B. 10*, 548). Prisms.

(κ)-Di-chloro-naphthalene  $C_{10}H_6Cl_2$  [94° uncor.]. Formed by heating (a)-naphthol sulphonic acid with  $PCl_5$  (Claus a. Oeler, *B. 15*, 314). On moderate oxidation it gives (a)-naphthoquinone and by further oxidation phthalic acid.

(γ)-Di-chloro-naphthalene  $C_{10}H_6Cl_2$  [1.4°] (Ekstrand, *B. 18*, 2881). [107°]. Formed by the action of  $PCl_5$  on (a)-nitro-naphthalene, or better, on (a')-di-nitro-naphthalene (Atterberg, *B. 9*, 317, 1188, 1734), and on (a)-nitro-naphthalene (a)-sulphonic acid (Clève, *Bl. 2* 24, 506).

Also from (a)-naphthylamine sulphonic acid (Laurent's naphthalidinic acid) by diazotisation and distillation of the resulting diazo-naphthalene sulphonic acid with  $PCl_5$  (Erdmann, *B. 20*, 6185). Formed synthetically from o-chloro-phenyl-paraconic acid. Scales. Gives a nitro-derivatives [142°], and a di-nitro-derivative [246°]. Oxidation by  $HNO_3$  gives chloro-nitro-phthalic acid.  $CrO_3$  in  $HOAc$  gives α-chloro-phthalic acid [184°] (Guaracchi, *G. 17*, 119).

(θ)-Di-chloro-naphthalene  $C_{10}H_6Cl_2$  [114°]. From naphthalene-(a')-di-sulphonic acid and  $PCl_5$  (Clève, *Bl. 2* 26, 244). Large tables; v. sol. boiling alcohol. Dilute  $HNO_3$  gives chloro-phthalic acid. It is perhaps  $C_{10}H_6Cl_2$  [2.2°].

(ι)-Di-chloro-naphthalene  $C_{10}H_6Cl_2$  [120°]. From naphthalene tetrachloride (4 pts.) and

Ag<sub>2</sub>O (3 pts.) at 200° (Leeds a. Everhart, *Am.* 2, 211). Formed, in very small quantity, when C<sub>10</sub>H<sub>7</sub>Cl<sub>2</sub> is decomposed by alcoholic KOH (Widmann, *B.* 15, 2162). Very thin laminae; sl. sol. cold alcohol.

(e) or (2,3')? Di-chloro-naphthalene C<sub>10</sub>H<sub>6</sub>Cl<sub>2</sub>. [136°]. (285° uncor.).

**Formation.**—1. By distilling (β)-chloro-naphthalene-sulphonic chloride with PCl<sub>5</sub>; the chloro-naphthalene-sulphonic acid being obtained either by sulphonation of (β)-chloro-naphthalene or by the action of cuprous chloride upon the diazo-compound from the (β)-naphthylamine-sulphonic acid obtained from (β)-naphthol sulphonic acid and NH<sub>3</sub> (Forsling, *B.* 20, 81; Arnell, *Bl.* [2] 45, 184).—2. From naphthalene ('β')-disulphonic acid, and from (β)-naphthol (α)-sulphonic acid by distilling with PCl<sub>5</sub> (Clève, *Bl.* [2] 25, 244; Armstrong a. Graham, *C. J.* 39, 142; Claus a. Zimmermann, *B.* 14, 1483). Needles (by sublimation) or large monoclinic tables (from alcohol). Volatile with steam. Sol. ether, chloroform, and benzene, sl. sol. alcohol. On oxidation it gives chloro-phthalic acid C<sub>8</sub>H<sub>5</sub>Cl(CO<sub>2</sub>H)<sub>2</sub> (4:2:1) and ('β')-di-chloro-(α)-naphthoquinone [149°] (Claus a. Müller, *B.* 18, 3073).

(γ)-Tri-chloro-naphthalene C<sub>10</sub>H<sub>3</sub>Cl<sub>3</sub>. [56°]. Prepared by heating di-chloro-naphthalene (β)-sulphonic chloride with PCl<sub>5</sub> (Widmann, *B.* 12, 962). Fine white needles. Insol. water, sl. sol. hot alcohol, v. sol. benzene.

(e)-Tri-chloro-naphthalene C<sub>10</sub>H<sub>3</sub>Cl<sub>3</sub>. [65°]. From γ-di-chloro-naphthalene by nitration and treatment of the resulting C<sub>10</sub>H<sub>2</sub>Cl<sub>2</sub>(NO<sub>2</sub>) with PCl<sub>5</sub> (Clève, *Bl.* [2] 29, 500). Needles, v. sol. alcohol.

(θ)-Tri-chloro-naphthalene C<sub>10</sub>H<sub>3</sub>Cl<sub>3</sub>. [76°]. From nitro-naphthalene ('α')-di-sulphonic acid and PCl<sub>5</sub> at 225° (Alén, *Bn.* II, 140). Small needles (from HOAc). V. sol. alcohol, m. sol. boiling HOAc.

(α')-Tri-chloro-naphthalene C<sub>10</sub>H<sub>3</sub>Cl<sub>3</sub>. [82°]. **Formation.**—1. By the action of alcoholic KOH upon (α)-chloro-naphthalene-tetra-chloride (Faust a. Saame, *A.* 160, 71).—2. By heating (α)-naphthol-di-sulphonic chloride with PCl<sub>5</sub> (3 mols.) at 170°-180° (Claus a. Mielcke, *B.* 19, 1182).

**Properties.**—Colourless needles. V. sol. chloroform, ether, and hot alcohol. HNO<sub>3</sub> at 200° gives tri-chloro-nitro-phthalic acid (Widmann, *Bl.* [2] 28, 511).

(β')-Tri-chloro-naphthalene C<sub>10</sub>H<sub>3</sub>Cl<sub>3</sub>. [90° uncor.]. (above 360°).

**Formation.**—1. By heating di-chloro-(α)-naphthol [101°], or sodium (α)-naphthol (β)-sulphonate with PCl<sub>5</sub> at 130°-140° (Claus a. Knyrim, *B.* 18, 2926).—2. By chlorinating (α)-nitro-naphthalene (Atterberg, *B.* 9, 926).

**Properties.**—Needles (from alcohol). May be sublimed. Insol. water, v. sol. other solvents.

Ti-chloro-naphthalene C<sub>10</sub>H<sub>2</sub>Cl<sub>4</sub>. [90°]. Formed together with di-chloro-(β)-naphthol [125°], by heating sodium (β)-naphthol (β)-disulphonate with 5 mols. of PCl<sub>5</sub> at 210°.

**Properties.**—Fine white needles. Sublimable. V. sol. ether, benzene, etc., and hot alcohol, sl. sol. cold alcohol. Heated with nitric acid (S.G. 1.16), at 210° it yields a syrupy di-

chloro-phthalic acid. By CrO<sub>3</sub> it is oxidised to the same di-chloro-phthalic acid, together with a tri-chloro-(α)-naphthoquinone which gives an anilide C<sub>10</sub>H<sub>2</sub>Cl<sub>3</sub>(NHPh)O<sub>2</sub> which melts at [228°]. Hence it appears to be different from the tri-chloro-naphthylene of melting-point [90°] already known (Claus a. Schmidt, *B.* 19, 3174).

(γ)-Tri-chloro-naphthalene C<sub>10</sub>H<sub>3</sub>Cl<sub>3</sub>. [103°]. Long white needles. Prepared by distillation of dichloro-naphthalene-(α)-sulphonic chloride with PCl<sub>5</sub> (Widmann, *B.* 12, 2230). Formed also by chlorinating (α)-nitro-naphthalene (Atterberg, *B.* 9, 317). Prisms. By heating to 170° with HNO<sub>3</sub> (1:42) it gives di-nitro-di-chloro-phthalic acid.

(η)-Tri-chloro-naphthalene C<sub>10</sub>H<sub>3</sub>Cl<sub>3</sub>. [113°]. From nitro-naphthalene (β)-disulphonic chloride and PCl<sub>5</sub> at 190° (Alén, *Bn.* II, 140). Needles (from HOAc). V. sol. warm alcohol; v. s. sol. benzene. Volatile with steam.

(θ)-Tri-chloro-naphthalene C<sub>10</sub>H<sub>3</sub>Cl<sub>3</sub>. [131°]. Formed by the action of PCl<sub>5</sub> on ('β')-di-nitro-naphthalene, nitro-(γ)-di-chloro-naphthalene, ('α') chloro-di-nitro-naphthalene [106°], ('β')-chloro-di-nitro-naphthalene, and nitro-(β')-di-chloro-naphthalene (Atterberg, *B.* 9, 1187, 1733; Widmann, *Bl.* [2] 28, 511). Long needles. Oxidation gives di-chloro-phthalic acid.

(α')-Tetra-chloro-naphthalene C<sub>10</sub>H<sub>2</sub>Cl<sub>4</sub>. [180°]. Formed by the action of alcoholic KOH on the ('α')-di-chloro-naphthalene ('α')-tetra-chloride, obtained by chlorinating naphthalene (Faust a. Saame, *A.* 160, 72). Formed in the same way from ('β')-di-chloro-naphthalene tetra-chloride, and from ('β')-tri-chloro-naphthalene dichloride (Widmann, *Bl.* [2] 28, 511). Long needles. Oxidation gives di-chloro-phthalic acid.

Tetra-chloro-naphthalene C<sub>10</sub>H<sub>2</sub>Cl<sub>4</sub>, i.e.

C<sub>10</sub>H<sub>2</sub>  $\begin{matrix} \diagup \text{CCl:CCl} \\ | \\ \diagdown \text{CCl:CCl} \end{matrix}$  (?). [146° uncor.]. Formed by heating (α)-naphthol-tri-sulphonic chloride with PCl<sub>5</sub> (4 mols.) at 210°-260°. Sublimes in colourless feathery needles. Crystallises from toluene in long thin needles. V. spl. hot alcohol, ether, chloroform, &c., sl. sol. cold alcohol, insol. water. On oxidation with CrO<sub>3</sub> or HNO<sub>3</sub> it is converted into di-chloro-(α)-naphthoquinone [189°],

C<sub>10</sub>H<sub>2</sub>  $\begin{matrix} \diagup \text{CO:CCl} \\ | \\ \diagdown \text{CO:CCl} \end{matrix}$ , together with chlorinated phthalic acids (Claus a. Mielcke, *B.* 19, 1184).

Tetra-chloro-naphthalene C<sub>10</sub>H<sub>2</sub>Cl<sub>4</sub>. [141°]. Formed by the action of alcoholic KOH on (γ)-di-chloro-naphthalene tetra-chloride (85°), and on tri-chloro-naphthalene di-chloride [93°] (Atterberg a. Widmann, *B.* 10, 1842). Slender needles; sl. sol. alcohol. May be identical with the preceding.

(ζ)-Tetra-chloro-naphthalene C<sub>10</sub>H<sub>2</sub>Cl<sub>4</sub>. [160-5°]. Formed by acting on (γ)-di-chloro-di-nitro-naphthalene with PCl<sub>5</sub> (Alén, *Bl.* [2] 36, 435). Interlacing needles.

(γ)-Tetra-chloro-naphthalene C<sub>10</sub>H<sub>2</sub>Cl<sub>4</sub>. [176°]. Obtained by the action of alcoholic KOH on ('α')-di-chloro-naphthalene ('α')-tetra-chloride got by chlorinating naphthalene (Widmann, *B.* 10, 1724; *Bl.* [2] 28, 512). Flat needles, sl. sol. alcohol.

(e)-Tetra-chloro-naphthalene C<sub>10</sub>H<sub>2</sub>Cl<sub>4</sub>. [180°]. From di-nitro-(γ)-di-chloro-naphthalene by dis-

tiling with  $\text{PCl}_5$  (Atterberg a. Widmann, *B.* 10, 1843). Long needles; sl. sol. alcohol.

( $\beta$ )-Tetra-chloro-naphthalene  $\text{C}_{10}\text{H}_4\text{Cl}_4$ . [194°]. Formed by chlorinating nitro-naphthalene (Atterberg, *B.* 9, 318). Needles, v. sl. sol. alcohol.

Penta-chloro-naphthalene  $\text{C}_{10}\text{H}_3\text{Cl}_5$ , i.e.

( $\beta$ )-Penta-chloro-naphthalene  $\text{C}_{10}\text{H}_3\text{Cl}_5$ . [177°]. From nitro-( $\beta$ )-tetra-chloro-naphthalene and  $\text{PCl}_5$  (Atterberg a. Widmann, *B.* 10, 1843). Needles. Oxidises to tri-chloro-phthalic acid.

Hexa-chloro-naphthalene  $\text{C}_{10}\text{H}_2\text{Cl}_6$ . [143°]. Formed by chlorinating tri-chloro-naphthalene (Laurent). Six-sided columns; v. sl. sol. alcohol, m. sol. ether. May be oxidised to hexa-chloro-naphthoquinone.

[194° uncor.]. Formed by heating tetra-chloro-( $\alpha$ )-naphthoquinone (1 pt.) with  $\text{PCl}_5$  (2 pts.) for 6 or 8 hrs. at  $250^\circ$ . Small colourless needles. Sublimable. By heating with  $\text{HNO}_3$  (1.5 S.G.) it is oxidised to penta-chloro-( $\alpha$ )-naphthoquinone [217°], and tetra-chloro-phthalic acid [250°] (Claus a. Wenzlik, *B.* 19, 1165; cf. Claus a. Lippe, *B.* 16, 1019).

Per-chloro-naphthalene  $\text{C}_{10}\text{Cl}_8$ . [203° uncor.]. (403°). Formed by heating tetra-chloro-oxy-naphthoquinone [265°] penta-chloro-( $\alpha$ )-naphthoquinone [217°], or ( $\alpha$ )-naphthol-tri-sulphonic chloride, with  $\text{PCl}_5$  at  $250^\circ$ . Prepared by the protracted chlorination of naphthalene in presence of  $\text{SbCl}_5$  (Berthelot a. Jungfleisch, *Bl.* [2] 9, 446; *A. Ch.* [4] 15, 332). Colourless needles. Sublimable (Claus a. Wenzlik, *B.* 19, 1169; Claus a. Mielcke, *B.* 19, 1186). By heating with  $\text{SbCl}_5$  at  $290^\circ$  it is split up into  $\text{C}_6\text{H}_5$ ,  $\text{C}_2\text{Cl}_4$ , and  $\text{CCl}_4$  (Rouff, *B.* 9, 1048). It is partially converted into naphthalene by passing with hydrogen through a red-hot tube.

DI-CHLORO-NAPHTHALENE TETRA-BROMIDE  $\text{C}_{10}\text{H}_2\text{Cl}_2\text{Br}_4$ . [c.  $100^\circ$ ]. • From di-chloro-naphthalene and  $\text{Br}_2$ .

( $\alpha$ )-CHLORO-NAPHTHALENE TETRA-CHLORIDE  $\text{C}_{10}\text{H}_3\text{Cl}_5$ . [181°]. • Formed by the action of  $\text{Cl}$  on naphthalene (Faust a. Saame, *A.* 160, 67) or on ( $\alpha$ )-chloro-naphthalene (Widmann, *B.* 10, 1724; *Bl.* [2] 28, 509). Monoclinic prisms (from chloroform). Oxidation gives phthalic acid. Alcoholic  $\text{KOH}$  forms ( $\alpha'$ )-tri-chloro-naphthalene.

( $\beta$ )-Chloro-naphthalene tetra-chloride  $\text{C}_{10}\text{H}_3\text{Cl}_5$ . From ( $\beta$ )-chloro-naphthalene and  $\text{Cl}$  (W.). Oil.

Di-chloro-naphthalene tetra-chloride  $\text{C}_{10}\text{H}_2\text{Cl}_6$ . [85°]. From ( $\gamma$ )-di-chloro-naphthalene and  $\text{Cl}$  (Atterberg a. Widmann, *B.* 10, 1841). Prisms. Alcoholic  $\text{KOH}$  gives ( $\delta$ )-tetra-chloro-naphthalene.

Di-chloro-naphthalene tetra-chloride  $\text{C}_{10}\text{H}_2\text{Cl}_6$ . [172°]. Formed by the action of  $\text{Cl}$  on ( $\alpha'$ ) or ( $\beta'$ )-di-chloro-naphthalene (Widmann, *Bl.* [2] 28, 506). Monoclinic prisms (from  $\text{CHCl}_3$ ). V. e. sol.  $\text{HOAc}$  and benzene. Oxidation gives di-chloro-phthalic acid. Alcoholic  $\text{KOH}$  gives ( $\alpha'$ ) tetra-chloro-naphthalene.

Di-chloro-naphthalene tetra-chloride  $\text{C}_{10}\text{H}_2\text{Cl}_6$ . Formed, together with the preceding, by the union of  $\text{Cl}$  with ( $\alpha'$ )-di-chloro-naphthalene. Oil. Alcoholic  $\text{KOH}$  gives ( $\gamma$ )-tetra-chloro-naphthalene.

( $\alpha'$ )-Tri-chloro-naphthalene di-chloride  $\text{C}_{10}\text{H}_3\text{Cl}_5$ . [93°]. From ( $\gamma$ )-di-chloro-naphthalene and  $\text{Cl}$  (Atterberg a. Widmann, *B.* 10, 1842). Alcoholic  $\text{KOH}$  converts it into ( $\delta$ )-tetra-chloro-naphthalene.

( $\beta'$ )-Tri-chloro-naphthalene di-chloride  $\text{C}_{10}\text{H}_3\text{Cl}_5$ . [152°]. Formed, together with  $\text{C}_{10}\text{H}_3\text{Cl}_5\text{HOAc}$  [195°], by passing chlorine into a solution of ( $\alpha$ )-chloro-naphthalene in glacial  $\text{HOAc}$  (Widmann, *Bl.* [2] 28, 507). Short prisms, sl. sol. alcohol.

CHLORO-NAPHTHALENE SULPHINIC ACID  $\text{C}_{10}\text{H}_7\text{ClSO}_2\text{H}$ . Formed by the action of sodium amalgam on ( $\alpha$ )-chloro-naphthalene sulphonic bromide (?) [115°] obtained from bromo-naphthalene sulphonic acid by  $\text{PCl}_5$  (Gessner, *B.* 9, 1504). Slender needles (from alcohol). —  $\text{BaA}$ , 1.3 aq.

( $\alpha$ )-CHLORO-NAPHTHALENE ( $\alpha$ )-SULPHONIC ACID  $\text{C}_{10}\text{H}_7\text{ClSO}_2\text{H}$ , i.e.  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_3\text{H})$  [1.4°]. Obtained by heating ( $\alpha$ )-diazo-( $\alpha$ )-naphthalene-sulphonic acid with  $\text{HCl}$ . V. sol. colourless tables (containing 2 aq).

Salts.— $\text{A'K}$ : silvery needles.— $\text{A'Na}$ : thin scales.— $\text{A'Ag}$ : thin tablets, v. sl. sol. cold water.  $\text{A'Ba}$  aq: sparingly soluble powder.

*Ethyl ether*  $\text{A'Et}$ : [46°]; large monosymmetrical prisms,  $a:b:c = 1.6785:1.7, \beta = 68^\circ 58'$ .

*Chloride*  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_2\text{Cl})$ : [95°]; large crystals (from chloroform).

*Amide*  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_2\text{NH}_2)$ : [226°]; sparingly soluble silvery scales (Clève, *B.* 20, 72).

( $\alpha$ )-Chloro-naphthalene ( $\beta$ )-sulphonic acid  $\text{C}_{10}\text{H}_7\text{ClSO}_3$ , i.e.  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_3\text{H})$  [1.2 or 3°]. Obtained by the action of  $\text{Cu}_2\text{Cl}_2$  upon the diazo-compound of the naphthylamine sulphonic formed by reduction of the ( $\beta'$ )-nitro-naphthalene ( $\beta$ )-sulphonic acid (sparingly soluble  $\text{Ba}$  salt), which is one of the products of the nitration of naphthalene ( $\beta$ )-sulphonic acid.

*Properties*.—V. sol. colourless rhombic tables. When heated in a current of steam it yields ( $\alpha$ )-chloro-naphthalene.

Salts.— $\text{A'Ag}$ : thin glistening tables, sol. hot water, sl. sol. cold.— $\text{A'Ba}$  aq: sparingly sol. crystalline powder.

*Ethyl ether*  $\text{A'Et}$ : [111°]; monosymmetrical crystals,  $a:b:c = 4.307:1.7, \beta = 86^\circ 45'$ ; v. e. sol. hot alcohol.

*Chloride*  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_2\text{Cl})$ : [114°]; small scales.

*Amide*  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_2\text{NH}_2)$ : [216°]; thin plates (Clève, *B.* 20, 74).

( $\alpha$ )-Chloro-naphthalene  $p$ -sulphonic acid  $\text{C}_{10}\text{H}_7\text{ClSO}_3$ , i.e.  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_3\text{H})$  [1.4°].

*Formation*.—1. By sulphonation of ( $\alpha$ )-chloro-naphthalene (Zinin, *J. pr.* 33, 86).—2. From ( $\alpha$ )-naphthylamine- $p$ -sulphonic acid (naphthionic

## CHLORO-NAPHTHALENE SULPHONIC ACID.

acid) by the action of  $\text{Cu}_2\text{Cl}_2$  upon its diazo-compound.

**Properties.**—Silvery plates. Converted by Br into chloro-bromo-naphthalene [67°].

**Salts.**— $\text{KA}'$ . —  $\text{BaA}'$ . —  $\text{ZnA}'$ . 6aq. —  $\text{CuA}'$ . 7aq. —  $\text{AgA}'$  aq (Arnell, *Bn.* ii. 153).

**Ethyl ether EtA'**: [104°]; large thin monoclinic tables,  $a:b:c = 1.3281:1.1:1.262$ ,  $\beta = 80^\circ 59'$ .

**Chloride**  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_2\text{Cl})$ : [95°]; gives, with  $\text{PCl}_5$ , ( $\beta'$ )-di-chloro-naphthalene [68°] (Arnell, *Bl.* [2] 39, 62).

**Amide**  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_2\text{NH}_2)$ : [187°] (Cleve, *B.* 20, 73).

(a)-Chloro-naphthalene sulphonic acid  $\text{C}_{10}\text{H}_7\text{ClSO}_3\text{H}$ . Formed in small quantity, together with the preceding, by sulphonating chloro-naphthalene with  $\text{ClSO}_3\text{H}$  (Armstrong a. Williamson, *C. J. Proc.* 2, 234).

**Chloride**  $\text{C}_{10}\text{H}_7\text{Cl}_2\text{SO}_2\text{Cl}$ : [127°]; short thick prisms.

( $\beta$ )-Chloro-naphthalene sulphonic acid  $\text{C}_{10}\text{H}_7\text{Cl}(\text{SO}_3\text{H})$ . Sparingly sol. water.

**Formation.**—1. By sulphonation of ( $\beta$ )-chloro-naphthalene by  $\text{H}_2\text{SO}_4$  or  $\text{ClSO}_3\text{H}$  (Arnell, *Bl.* [2] 45, 184). It appears to be formed by isomeric change from the preceding by heating to 150° (Armstrong a. Wynne, *C. J. Proc.* 3, 22, 145).—2. By the action of cuprous chloride upon diazotised ( $\beta$ )-naphthylamine-sulphonic acid obtained by treatment of ( $\beta$ )-naphthol sulphonic acid with  $\text{NH}_3$ .

**Salts.**— $\text{BaA}'$ . —  $\text{KA}'$ .  $\frac{1}{2}$ aq.

**Chloride**  $\text{C}_{10}\text{H}_7\text{Cl}_2(\text{SO}_2\text{Cl})$ : [110°]; needles; by distillation with  $\text{PCl}_5$  it gives ( $\epsilon$ )-di-chloro-naphthalene [136°].

**Amide**  $\text{C}_{10}\text{H}_7\text{Cl}_2(\text{SO}_2\text{NH}_2)$ : [184°]; needles (Forsling, *B.* 20, 80).

( $\beta$ )-Chloro-naphthalene sulphonic acid  $\text{C}_{10}\text{H}_7\text{ClSO}_3\text{H}$  [2:3]?

**Formation.**—1. By heating ( $\beta$ )-chloro-naphthalene with fuming  $\text{H}_2\text{SO}_4$ , and separated from the preceding acid through the greater solubility of its lead salt (Arnell, *Bl.* [2] 45, 184).—2. By diazotising ( $\beta$ )-naphthylamine sulphonic acid, and boiling with conc.  $\text{HCl}$  (Forsling, *B.* 19, 1715).

**Properties.**—Trimetric scales. —  $\text{BaA}'$ . 4aq: laminae. —  $\text{KA}'$  aq: small scales.

**Chloride** [129°]. Converted by  $\text{PCl}_5$  into di-chloro-naphthalene [61.5°].

Di-chloro-naphthalene (a)-sulphonic acid  $\text{C}_{10}\text{H}_6\text{Cl}_2(\text{SO}_3\text{H})$ . Prepared by boiling the tetrachloride of (a)-naphthalene-sulphonic chloride with alcoholic  $\text{KOH}$  (Widmann, *B.* 12, 2223). Long flat needles. M. sol. cold water.

**Salts.**— $\text{AK}$  2aq: fine needles. —  $\text{A'Na}$  aq: long flat prisms. —  $\text{A'Ag}$  2aq: white needles. —  $\text{A'Ca}$  4aq: slightly soluble leaflets.

**Chloride** [145°]. Scales or needles. Sol. benzene and hot acetic acid. By distillation with  $\text{PCl}_5$  it gives ( $\gamma$ )-tri-chloro-naphthalene.

**Amide** [about 250°]. Flat feathery crystals.

Di-chloro-naphthalene ( $\beta$ )-sulphonic acid  $\text{C}_{10}\text{H}_6\text{Cl}_2(\text{SO}_3\text{H})$ . Prepared by boiling the tetrachloride of naphthalene-( $\beta$ )-sulphonic chloride ( $\text{C}_{10}\text{H}_5(\text{SO}_2\text{Cl})\text{Cl}$ ) with alcoholic  $\text{KOH}$  (Widmann, *B.* 12, 959). Readily sol. hot water, less in cold. Strong acid.

**Salts.**— $\text{AK}$  5aq: very fine needles. S. 2-5 at 16°. —  $\text{AK}$   $\frac{1}{2}$ aq. —  $\text{AK}$   $\frac{1}{2}$ aq: small prisms.—

$\text{A'Ag}$  aq: crystalline powder. —  $\text{A'Ba}$  4aq: fine sparingly soluble needles. —  $\text{A'Ca}$  2aq.

**Chloride** [133°]; fine white needles. Sol.  $\text{C}_6\text{H}_6$  and  $\text{CS}_2$ .

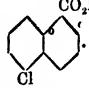

**Amide** [245°]; fine needles. Insol. water, sol. alcohol.

Tri- and Tetra-chloro-naphthalene sulphonic acids have been described by Laurent (*A.* 72, 299), but not sufficiently characterised.

**CHLORO-NAPHTHALIC ACID**, v. CHLOROXY-(a)-NAPHTHOQUINONE.

**CHLORO-NAPHTHOHYDROQUINONE** v. CHLORO-HYDRO-NAPHTHOQUINONE.

**CHLORO-(a)-NAPHTHOIC ACID**

$\text{C}_{10}\text{H}_7\text{Cl}(\text{CO}_2\text{H})$ , probably  [245°].

**Formation.**—1. By chlorination of (a)-naphthoic acid in acetic acid solution.—2. By the action of cuprous chloride upon the diazo-compound obtained from nitro-(a)-naphthoic acid [239°].—3. From the nitrile.

**Properties.**—Sublimes in white needles. By fuming  $\text{HNO}_3$  it is converted into chloro-nitro-(a)-naphthoic acid [225°] and chloro-di-nitro-naphthalene [175°] (Ekstrand, *B.* 17, 1604; 18, 2381).

**Salt.**— $\text{A'Ca}$  2aq: needles; S. 86.

**Ethyl ether A'Et**: [42°]; quadratic tables.

**Amide**  $\text{C}_{10}\text{H}_7\text{Cl}(\text{CONH}_2)$ . [239°]. Formed by boiling the nitrile with alcoholic  $\text{KOH}$  (Ekstrand, *Bn.* ii. 925).

**Nitrile**  $\text{C}_{10}\text{H}_6\text{Cl}_2\text{CN}$  [145°]. White needles. Formed by chlorination of (a)-naphthonitrile (Ekstrand, *B.* 17, 1604).

Chloro-( $\beta$ )-naphthoic acid  $\text{C}_{10}\text{H}_7\text{Cl}_2\text{CO}_2\text{H}$ . [261°]. From the nitrile and fuming  $\text{HCl}$  at 150° (Ekstrand, *Bn.* ii. 931). Needles (from alcohol).

**Ethyl ether EtA'**. [45°]. Needles.

**Nitrile**  $\text{C}_{10}\text{H}_6\text{Cl}_2\text{CN}$ . [138°]. From (a)-naphthonitrile in  $\text{HOAc}$  by chlorinating in presence of iodine.

Di-chloro-( $\beta$ )-naphthoic acid  $\text{C}_{10}\text{H}_6\text{Cl}_2\text{CO}_2\text{H}$  [221° uncor.]. Sublimable. Colourless needles. Sparingly soluble in alcohol and in acetic acid. Formed by chlorination of ( $\beta$ )-naphthoic acid.

**Salts.**— $\text{A'Ca}$  2 $\frac{1}{2}$ aq: small sparingly soluble prisms.

**Ethyl ether A'Et**: [66°]; long needles. S. 03 (Ekstrand, *B.* 17, 1605).

(a,a')-CHLORO-NAPHTHOL  $\text{C}_{10}\text{H}_7\text{Cl}(\text{OH})$  [1:4]. [57°]. Formed by the action of  $\text{PCl}_5$  on (a)-naphthol-sulphonic acid. Small felted needles. On moderate oxidation it gives (a)-naphthoquinone, and by further oxidation phthalic acid (Claus a. Oehler, *B.* 15, 312).

Chloro-(a)-naphthol  $\text{C}_{10}\text{H}_7\text{Cl}(\text{OH})$ . [109°]. Formed by distilling the compound  $\text{C}_{10}\text{H}_7(\text{HOCl})$ , with aqueous  $\text{HCl}$  (Grimaux, *B.* [2] 18, 209). Slender needles.

( $\beta$ )-Chloro-(a)-naphthol  $\text{C}_{10}\text{H}_6\text{Cl}(\text{OH})$  [2:1] [c. 54°]. Is contained in the mother liquors obtained by passing chlorine into a solution of (a)-naphthol in  $\text{HOAc}$  (Cleve, *B.* 21, 894).

V. e. sol. most menstrua; only crystallisable from petroleum ether.

Chlorine forms di-chloro-naphthol [106°].  $\text{PCl}_5$  yields tri-chloro-naphthalene [92°].

**Chloro-( $\beta$ )-naphthol**,  $C_{10}H_7Cl(OH)$  [1:2]. [68°] (S.); [70°] (C.). Formed by the action of chlorine on ( $\beta$ )-naphthol sodium suspended in CS<sub>2</sub> (Schall, B. 16, 1901), or dissolved in HOAc (Cleve, B. 21, 896).

Needles or monoclinic plates (from chloroform);  $a:b:c = 1.96:1.1:956$ ;  $\beta = 66^\circ 54'$ . Volatile with steam. Converted by  $PCl_5$  into chloro-naphthyl phosphate ( $C_{10}H_6Cl_2PO_4$ , [152°] or, at a higher temperature, into (1, 2)-di-chloro-naphthalene [84°].

[101° uncor.]. (308°). Formed by heating sodium ( $\beta$ )-naphthol ( $\beta$ )-sulphonate (Rumpf's acid) (1 mol.) with  $PCl_5$  (2 mols.) at  $150^\circ$ – $160^\circ$ . Fine colourless needles. V. s. sol. alcohol, ether, etc., sl. sol. water. Volatile with steam. By further action of  $PCl_5$  it yields di-chloro-naphthalene [61°] (Claus a. Volz, B. 18, 3167).

**Chloro-( $\beta$ )-naphthol**  $C_{10}H_7Cl.OH$ . [115° uncor.]. Formed, together with ( $\epsilon$ )-di-chloro-naphthalene, by heating potassium ( $\beta$ )-naphthol-sulphonate with  $PCl_5$  (3 mols.) to  $170^\circ$  (Claus a. Zimmermann, B. 14, 1484). Fine needles or prisms. Sol. alcohol, ether, and hot water. Not volatile with steam.

[101° uncor.]. Formed by heating sodium ( $\alpha$ )-naphthol-( $\beta$ )-sulphonate (1 mol.) with  $PCl_5$  (2–2½ mols.) at  $100^\circ$ – $120^\circ$ . Sublimes in white needles. V. sol. ordinary solvents. By further treatment with  $PCl_5$  it is converted into tri-chloro-naphthalene [90°]. By dilute  $HNO_3$  at  $200^\circ$  it is oxidised to phthalic acid. By boiling with an acetic solution of  $CrO_3$  it is oxidised to di-chloro-( $\alpha$ )-naphthoquinone  $C_6H_4 \begin{array}{l} \diagup CO.CCl \\ \diagdown CO.CCl \end{array}$  [189°].

(Claus a. Knyrim, B. 18, 2926).

**Di-chloro-( $\alpha$ )-naphthol**  $C_{10}H_6Cl_2(OH)$  [1:3:4]. [106°] (C.); [108°] (Zincke, B. 21, 1027). Formed by passing chlorine into a cold solution of ( $\alpha$ )-naphthol in HOAc (Cleve, B. 21, 891). Needles. Sol. alcohol, chloroform, benzene. Crystallises from HOAc as  $C_{10}H_6Cl_2.OH + HOAc$  losing HOAc at  $40^\circ$ – $50^\circ$ .

**Reactions.**—1. Yields on heating a substance  $C_{10}H_6Cl_2O_2$  (?).—2. Dilute  $HNO_3$  forms yellow needles of a quinone-like substance and phthalic acid.—3. Oxidation with chromic acid forms chloro-naphthoquinone [116°], which on heating with aniline forms the anilide [208°] (cf. Knapp and Schultz, A. 230, 189).—4.  $PCl_5$  forms (1,3,4) tri-chloro-naphthalene.

**Acetyl derivative**  $C_{10}H_6Cl_2OAc$ . [76°].

**Di-chloro-( $\beta$ )-naphthol**  $C_{10}H_6Cl_2(OH)$ . [125° uncor.]. Formed, together with tri-chloro-naphthalene [90°], by heating sodium ( $\beta$ )-naphthol-( $\beta$ )-di-sulphonate with  $PCl_5$  at  $210^\circ$ . Colourless felted needles. Sublimable. V. sol. alcohol, ether, etc., sl. sol. hot water (Claus a. Schmidt, B. 19, 8174).

**Tri-chloro-( $\alpha$ )-naphthol**  $C_{10}H_4Cl_3(OH)$  [4:3:2:1]. [100°]. From tri-chloro-naphthol dichloride and  $NaHSO_3$  (Zincke, B. 21, 1027). Silky needles (from HOAc).  $CrO_3$  oxidises it to di-chloro-( $\alpha$ )-naphthoquinone.

**Acetyl derivative**  $C_{10}H_4Cl_3OAc$ . [124°].

[121°]. From ( $\alpha$ )-naphthol in HOAc by chlorination (Z.). Flat monoclinic prisms; v. s. sol. benzene. Boiling dilute alcohol converts it into chloro-( $\alpha$ )-naphthoquinone. Hydroxylamine hydrochloride appears to form an oxim [c. 148°], a compound  $C_{10}H_4Cl_3(NO)$ , and a third body [205°].

Two modifications, corresponding perhaps to the above formulae, are formed by chlorinating tri-chloro-( $\alpha$ )-naphthol (Z.), viz. rhombic prisms [105°] and prisms [94°]. Boiling dilute alcohol or dilute HOAc convert both into di-chloro-( $\alpha$ )-naphthoquinone. Dilute alcoholic KOH forms chloro-oxy-naphthoquinone. KOH in absolute alcohol appears to form

**TRI-CHLORO-( $\alpha$ )-NAPHTHOL DICHLORIDE**

$C_6H_3 \begin{array}{l} \diagup CO.CCl_2 \\ \diagdown CCl_2.CHCl \end{array}$  [157°]. From Cl and ( $\alpha$ )-naphthol in cold HOAc (Zincke, B. 21, 1027). Monoclinic plates (from benzene).  $NaHSO_3$  in presence of HOAc reduces it to tri-chloro-( $\alpha$ )-naphthol. Dilute alcohol or dilute HOAc at  $130^\circ$  form di-chloro-( $\alpha$ )-naphthoquinone. Alcoholic aniline forms  $C_6H_3 \begin{array}{l} \diagup CO-C(NPh)H \\ \diagdown C(NPh):CCl \end{array}$

[157°] whence  $B'H_2PtCl_4$ .

**Tetra-chloro-( $\alpha$ )-naphthol dichloride**

( $\alpha$ )-naphthol,  $MnO_2$ , and  $HCl$  (Z.). V. sol. benzene and hot alcohol, sl. sol. ether. Does not react with aniline. May be reduced to tri-chloro-( $\alpha$ )-naphthol. Alcoholic KOH forms  $CCl_2.CCl.CO.C_6H_3.CO.H$  [128°].

**CHLORO-( $\alpha$ )-NAPHTHOQUINONE**  $C_{10}H_6ClO$ ,

B. 21, 891); [118°] (Zincke, B. 21, 1027). A by-product in the preparation of di-chloro-( $\alpha$ )-naphthoquinone [189°] by treating di-nitro-( $\alpha$ )-naphthol with  $KClO_4$  and  $HCl$  (Plagemann, B. 15, 486).

The following amides are formed by treating di-chloro-( $\alpha$ )-naphthoquinone with the corresponding amine in alcoholic solution (P.):

**Methylamide**  $C_{10}H_6ClO.NMeH$ . [150°].

Orange needles, v. sol. alcohol.

**Di-methylamide**  $C_{10}H_6ClO.NMe_2$ . [85°].

Scarlet needles, v. sol. alcohol.

**Ethylamide**  $C_{10}H_6ClO.NEtH$ . [110°].

Brownish-red needles, v. sol. alcohol.

**Anilide**  $C_{10}H_6ClO.NHC_6H_5$ . [208°] (P.); [202°] (K. a. S.; C.). Red metallic needles. Sol.

acetic acid and alkalis, sl. sol. alcohol. Its solution in conc.  $H_2SO_4$  is of a magenta colour.  $SnCl_4$  reduces it to a dihydride [170°] (Knapp a. Schultz, A. 210, 189).

**Nitrosamine**  $C_{10}H_7ClO_2N(NO)C_6H_5$ : [126°]; yellow needles or plates, sol. benzene, sl. sol. ligroin; formed by passing nitrous acid into the anilide suspended in acetic acid (Plagemann, B. 16, 896).

**p-Bromo-anilide**  $C_{10}H_6ClO_2.NHC_6H_4Br$ : [262°]. Formed by bromination of chloro-naphthoquinone-anilide; or by the action of *p*-brom-aniline on di-chloro-naphthoquinone. Sol. in  $NaOH$  to a red solution, sl. sol. alcohol and acetic acid.

**m-Nitro-anilide**  $C_{10}H_6ClO_2.NHC_6H_4(NO_2)$ : [245°]. Formed by the action of *m*-nitraniline on di-chloro-naphthoquinone. Yellowish-red sparingly soluble needles.

**p-Nitro-anilide**  $C_{10}H_6ClO_2.NHC_6H_4(NO_2)$ : [282°]. Formed by the action of *p*-nitraniline on di-chloro-naphthoquinone; or by nitration of chloro-naphthoquinone-anilide. Red felted needles. Sl. sol. alcohol and acetic acid, sol. alkalis to a violet solution. **Nitrosamine**  $C_{10}H_6ClO_2N(NO)C_6H_4(NO_2)$ : [128°].

**o-Toluide**  $C_{10}H_6ClO_2.NHC_6H_4(CH_3)$ : [162°]. Red metallic crystals. Formed by the action of *o*-toluidine on di-chloro-naphthoquinone.

**p-Toluide**  $C_{10}H_6ClO_2.NHC_6H_4(CH_3)$ : [196°]. Formed by the action of *p*-toluidine on di-chloro-naphthoquinone. Metallic red crystals. Sol. acetic acid, sl. sol. alcohol. Dissolves in  $NaOH$  to a violet solution.

**Bromo-o-toluide**  $C_{10}H_5ClO_2.NHC_6H_3(CH_3)Br$ : [212°]. Formed by bromination of chloro-naphthoquinone-*o*-toluide. Sl. sol. alcohol and acetic acid.

**Bromo-p-toluide**  $C_{10}H_5ClO_2.NHC_6H_3(CH_3)Br$ : [185°]. Formed by bromination of chloro-naphthoquinone-*p*-toluide. Red needles. Sl. sol. alcohol, dissolves in  $NaOH$  to a violet solution.

**Nitro-o-toluide**  $C_{10}H_5ClO_2.NHC_6H_3(CH_3)(NO_2)$ : [230°]. Formed by nitrating the *o*-toluide (P.).

**Nitro-p-toluide**  $C_{10}H_5ClO_2.NHC_6H_3(CH_3)(NO_2)$ : [236°-240°]. Formed by nitration of chloro-naphthoquinone-*p*-toluide. Red felted needles. Sl. sol. alcohol and acetic acid. Dissolves in  $NaOH$  to a violet solution.

**Chloro-(β)-naphthoquinone**  $C_{10}H_6ClO_2$   $\begin{matrix} \text{CO.CO} \\ \diagup \quad \diagdown \\ C_6H_4 \\ \diagdown \quad \diagup \\ \text{CH:Cl} \end{matrix}$  [172°]. Obtained by passing chlorine gas into (β)-naphthoquinone suspended in ten times its weight of acetic acid. Red needles. Sol. hot alcohol, acetic acid, benzene, and chloroform. Dissolves in dilute caustic alkalis with a reddish-brown colour forming chloro-oxy-(α)-naphthoquinone. With alcoholic  $NH_3$  or aniline it yields respectively the imide or anilide of chloro-oxy-(α)-naphthoquinone (Zincke, B. 19, 2497).

**Dichloride**  $C_{10}H_4Cl_2O_2$   $\begin{matrix} \text{CO.CO} \\ \diagup \quad \diagdown \\ C_6H_2 \\ \diagdown \quad \diagup \\ \text{CHCl:CCl} \end{matrix}$  [128°]. Formed by passing chlorine into a solution of (β)-naphthoquinone in  $HOAc$  (Zincke, B. 20, 2890). Thin needles (containing 2aq). In the

hydrated condition it melts at 112°. Methyl-

amine forms  $C_{10}H_6ClO_2$   $\begin{matrix} \text{CO.C(OH)} \\ \diagup \quad \diagdown \\ C_6H_4 \\ \diagdown \quad \diagup \\ \text{C(NMe):CCl} \end{matrix}$  [200°].

**Di-chloro-(α)-naphthoquinone**  $C_{10}H_6Cl_2O_2$  i.e.  $C_{10}H_6$   $\begin{matrix} \text{CO.CCl} \\ \diagup \quad \diagdown \\ C_6H_4 \\ \diagdown \quad \diagup \\ \text{CO.CCl} \end{matrix}$  [189°].

**Formation.**—1. From chloro-naphthalene tetrachloride  $O_2H_2Cl_4$  and boiling  $HNO_3$  (Lafrent, A. Ch. [2] 74, 35; Rev. Scient. 13, 591).—2. From di-nitro-naphthol,  $KClO_4$  and  $HCl$  (Graebe, A. 149, 3).—3. From naphthalene in  $HOAc$  and  $CrO_2Cl_2$  (Carstanjen, B. 2, 633).—4. Together with chlorinated phthalic acids by oxidation of tetra-chloro-naphthalene [140°] (from (α)-naphthol-tri-sulphonic chloride and  $PCl_5$  with  $CrO_3$  or  $HNO_3$ ).

**Properties.**—Sublimes in yellow needles. Insol. water, sl. sol. cold alcohol and ether. By alkalis it is converted into chloro-oxy-(α)-naphthoquinone which forms yellow needles [215°]. With aniline it yields  $C_{10}H_6Cl(NHPh)O_2$ , splendid violet-red crystals [203° uncor.] (Claus a. Mielcke, B. 19, 1184). Oxidation gives phthalic acid.  $PCl_5$  forms penta-chloro-naphthalene.

**Di-chloride**  $C_{10}H_4Cl_2O_2$ : [117° uncor.]. Formed by heating di-chloro-(α)-naphthoquinone (10 pts.) with  $HCl$  of S.G. 1.2 (48 pts.) and  $MnO_2$  (10 pts.) for 10 hours at 230°. Large colourless prisms. Sublimes unaltered. By  $SnCl_4$  or other reducing agent it is re-converted into di-chloro-(α)-naphthoquinone (Claus, B. 19, 1142).

**(β')-Di-chloro-(α)-naphthoquinone**  $C_{10}H_4Cl_2O_2$  probably  $C_{10}H_4$   $\begin{matrix} \text{CO.CCl} \\ \diagup \quad \diagdown \\ C_6H_2 \\ \diagdown \quad \diagup \\ \text{CO.CH} \end{matrix}$  [149° un-

cor.]. Formed, together with chloro-phthalic acid  $C_6H_4Cl(CO_2H)$ , [4:2:1], by oxidation of (ε)-di-chloro-naphthalene in acetic acid solution by  $CrO_3$ . Yellow needles. Sublimable without decomposition. Dissolves in aqueous  $KOH$  with a red colour. By boiling with alkalis it is converted into (β')-chloro-oxy-naphthoquinone  $C_{10}H_4Cl(OH)O_2$  (Claus a. Müller, B. 18, 3073).

**Di-chloro-(α)-naphthoquinone**  $C_{10}H_4Cl_2O_2$ : [153°]. Formed, together with the isomeride [189°] by chlorinating di-nitro-naphthol (P.).

**p-Di-chloro-(α)-naphthoquinone**  $C_{10}H_4Cl_2O_2$ : [174°]. Formed, together with di-chloro-phthalide, by oxidation of di-chloro-naphthalene [88°] with  $CrO_3$  and glacial acetic acid. Long yellow needles. Sublimable. Sol. alcohol and ether, nearly insol. water. By  $NaOH$  it is converted into chloro-oxy-(α)-naphthoquinone. With aniline it forms  $C_{10}H_4Cl(NHPh)O_2$ , garnet red needles, [185°] (Guarascio, B. 19, 1155).

**Di-chloro-(β)-naphthoquinone**  $C_{10}H_4$   $\begin{matrix} \text{CO.CO} \\ \diagup \quad \diagdown \\ C_6H_2 \\ \diagdown \quad \diagup \\ \text{CCl:CCl} \end{matrix}$  [184°]. Formed by the action of chlorine upon (β)-naphthoquinone, or better (α)-amido-(β)-naphthol in acetic acid. Red plates, long flat needles, thick rhombic or monoclinic tables. Sol. chloroform, sl. sol. alcohol. Sublimable. With alcoholic  $NH_3$ , or aniline it yields the imide or anilide of chloro-oxy-(α)-naphthoquinone. It dissolves in cold dilute  $NaOH$  to a colourless solution forming an acid  $C_{10}H_4Cl_2O_2$  which pos-

sibly has the constitution  $C_6H_4 \begin{matrix} C(OH).CO_2H \\ \diagdown \\ CO_2Cl \end{matrix}$ .

(Zincke, *B.* 19, 2499). This acid crystallises in slender needles (containing aq) [100°]; it forms a methyl-ether  $C_{10}H_7Cl_2(OH).CO_2Me$  [138°] and an acetyl-methyl ether  $C_{10}H_7Cl_2(OAc).CO_2Me$  [76°].

Tri-chloro-(a)-naphthoquinone  $C_{10}H_5Cl_3O_2$ . Formed by oxidation of tri-chloro-naphthalene [96°] (from (β)-naphthol-(β)-di-sulphonic acid and  $PCl_5$ ) with  $CrO_3$  and acetic acid. It was not isolated, but by treatment with aniline was converted into the anilide  $C_{10}H_5Cl_3(NHPh)O_2$ , which formed reddish-violet plates [228°] uncor., sublimable (Claus a. Schmidt, *B.* 19, 8177).

Tetra-chloro-(a)-naphthoquinone  $C_{10}H_4Cl_4O_2$ . [160° uncor.]. Long yellow needles. Sublimable. Prepared by oxidation of penta-chloro-naphthalene with fuming  $HNO_3$  at 110°.  $PCl_5$  converts it into hepta-chloro-naphthalene (Claus a. Lippe, *B.* 16, 1018).

Penta-chloro-(a)-naphthoquinone  $C_{10}H_3Cl_5O_2$ . [217° uncor.]. Formed together with tetra-chloro-phthalic acid, by oxidation of hepta-chloro-naphthalene [194°] with  $HNO_3$  (1.5 S.G.) at 100°. Glistening golden plates (from chloroform). Sublimes in long glistening needles. By alkalis it is converted into salts of tetra-chloro-oxy-naphthoquinone  $C_{10}H_2Cl_4O_3$ . With aniline it yields  $C_{10}H_2Cl_4O_3(NHC_6H_5)$ , which crystallises from alcohol or acetic acid in glistening red plates [240° uncor.]. By heating with  $PCl_5$  at 250° it is converted into per-chloro-naphthalene [203°] (Claus a. Wenzlik, *B.* 19, 1166).

DI-CHLORO-(β)-NAPHTHOQUINONE DI-CHLORIDE  $C_{10}H_6Cl_2$ . [91°]. Formed by passing chlorine into a solution of (1, 2)-amido-naphthol in  $HOAc$  (Zincke, *B.* 21, 495). Yellowish crystals (from ether); v. sol. ether,  $HOAc$ , and petroleum ether.

DI-CHLORO-(a)-NAPHTHOQUINONE SULPHONIC ACID  $C_{10}H_5Cl_2O_5(SO_3H)[2:3:1:4:3]$ . From sodium di-nitro-(a)-naphthol sulphonate ((a)-naphthol yellow),  $KClO_3$  and  $HCl$  (Claus, *J. pr.* [2] 87, 181). Light yellow plates v. sol. water and alcohol, insol. ether. Converted by potash-fusion into (β)-oxy-phthalic acid. Aniline forms  $C_{10}H_5Cl_2(NHPh)O_5(SO_3H)[190°]$ , a colouring matter crystallising in dark-red plates.

Salts.— $Na^+$ : yellow crystalline powder (from water) or yellow plates (from alcohol).— $Ca^{2+}$ .— $Ba^{2+}$ .

DI-CHLORO-NAPHTHOSTYRIL o. Di-CHLORO-AMIDE-NAPHTHOIC LACTAM.

TETRA-CHLORO-(β)-DINAPHTHYL  $C_{20}H_8Cl_4$ . Amorphous (Smith a. Poynting, *C. J.* 27, 854).

Hexa-chloro-(aa)-dinaphthyl  $C_{20}H_2Cl_6$ . Amorphous (Cossen, *A.* 144, 77).

CHLORO-(a)-NAPHTHYLAMINE  $C_{10}H_7ClN$  i.e.  $C_6H_4 \begin{matrix} C(NH_2).CH \\ \diagdown \\ CH=CCl \end{matrix}$  or  $C_6H_4 \begin{matrix} C(NH_2).COCl \\ \diagdown \\ CH=CH \end{matrix}$ .

[56°]. Obtained by reduction of di-chloro-(a)-naphthylamine [82°] with tin and  $HCl$ . Thin white needles. Very unpleasant smell. Sl. sol. hot water. Very volatile with steam. Its salts are decomposed by water.

Salts.— $B^+HCl^-$  aq: silky needles.— $B^+HClSnCl_6^-$ : thin glistening plates.— $B^+H_2SO_4^-$ : slender white needles (Clève, *B.* 20, 450).

Chloro-(a)-naphthylamine  $C_{10}H_7Cl(NH_2)$ . [86°]. From chloro-nitro-naphthalene by reduction (Atterberg, *B.* 10, 548).— $B^+HCl^-$ .

Chloro-(a)-naphthylamine  $C_{10}H_7Cl(NH_2)$ . [94°]. Formed by reducing (γ)-di-chloro-nitro-naphthalene (Atterberg, *B.* 9, 1730).  $Fe_2O_3$  gives a greyish-green coloration. Displacement of  $NH_2$  by  $Cl$  forms (δ)-di-chloro-naphthalene (Atterberg, *B.* 10, 548).— $B^+HCl^-$  aq.— $B^+HSnCl_6^-$ .

Chloro-(a)-naphthylamine  $C_{10}H_7Cl(NH_2)$ . [98°]. Formed by the slow action of  $SnCl_4$  on a solution of (a)-naphthylamine hydrochloride exposed to air (Seidler, *B.* 11, 1201).

Acetyl derivative  $C_{10}H_7Cl(NHAc)$ . [184°]. (a)-Chloro-(β)-naphthylamine  $C_{10}H_7Cl(NH_2)$ . [1.2]. [59°]. From the acetyl derivative and  $HCl$ . Elimination of  $NH_2$  gives (a)-chloro-naphthalene.— $B^+HCl^-$  aq.

Acetyl derivative  $C_{10}H_7Cl.NHAc$ . [147°]. Formed by passing chlorine into a solution of acetyl (β)-naphthylamine in dilute  $HOAc$  (Clève, *B.* 20, 1389).

Di-chloro-(a)-naphthylamine  $C_{10}H_6Cl_2(NH_2)$ . [101°]. Formed by reducing (β)-di-chloro-nitro-naphthalene [68°]. Needles (from alcohol).  $B^+HCl^-$ .— $B^+HSnCl_6^-$ .— $B^+H_2P_2Cl_7^-$  2aq.— $B^+H_2SO_4^-$ .

(γ)-Di-chloro-naphthylamine  $C_{10}H_6Cl_2(NH_2)$ . [94°?]. Formed by reducing (γ)-di-chloro-nitro-naphthalene (Clève, *Bl.* [2] 29, 500).— $B^+HCl^-$ .

Di-chloro-(a)-naphthylamine  $C_{10}H_6Cl_2N$  probably  $C_6H_4 \begin{matrix} C(NH_2).COCl \\ \diagdown \\ CH=CCl \end{matrix}$ . [82°]. Obtained by

saponifying its acetyl derivative, which is formed by passing chlorine (2 mols.) into an acetic acid solution of acetyl-(a)-naphthylamine (1 mol.). Crystalline solid, of disagreeable odour. V. a. sol. alcohol. Volatile with steam. Non-basic. By  $HNO_3$  it is oxidised to phthalic acid. By elimination of the  $NH_2$  group by the diazo-reaction, di-chloro-naphthalene [61°] is formed. By tin and  $HCl$  it is reduced to mono-chloro-(a)-naphthylamine [56°].

Acetyl derivative  $C_{10}H_6Cl_2.NHAc$ : [214°]; long thin white needles; sol. acetic acid, alcohol and chloroform; sublimable (Clève, *B.* 20, 448).

DI-CHLORO-DI-(β)-NAPHTHYLAMINE  $(C_{10}H_7Cl)_2NH$ .

Benzoyl derivative  $(C_{10}H_7Cl)_2NBz$ . [203° uncor.]; small white needles; sol. alcohol, benzene, and chloroform. Formed by the action of  $PCl_5$  on the benzoyl derivative of di-(β)-naphthylamine (Claus a. Richter, *B.* 17, 1590).

DI-CHLORO-NAPHTHYLENE-DIAMINE  $C_{10}H_6Cl_2(NH_2)_2$ . [205°]. Formed by reduction of di-chloro-di-nitro-naphthalene [253°] by tin,  $HCl$ , and  $HOAc$  (Alén, *Bl.* [2] 36, 435).

**DI-CHLORO-( $\alpha$ )-DINAPHTHYLENE-OXIDE**  $C_{10}H_6Cl_2O$ . [151°]. Prepared by the action of  $PCl_5$  on ( $\alpha$ )-dinaphthylene-oxide (Knecht & Unzeitig, B. 18, 1725). Sublimes and crystallises in yellow needles. V. sol. benzene and acetic acid, sl. sol. alcohol, ether, and chloroform.

**Di-chloro-( $\beta$ )-dinaphthylene-oxide**  $C_{10}H_6Cl_2O$ . [245°]. Prepared by the action of  $PCl_5$  on ( $\beta$ )-dinaphthylene-oxide (K. & A. U.). Yellow glistening needles (from benzene).

**TRI-CHLORO-( $\alpha$ ) and ( $\beta$ )-DI-NAPHTHYLETHANE**  $CCl_3CH(C_{10}H_7)_2$ . Formed together by the action of  $H_2SO_4$  on a mixture of naphthalene and chloral, thus:  $CCl_3CH.O + 2C_{10}H_7 = CCl_3CH(C_{10}H_7)_2 + H_2O$ .

**Preparation.**—6 pts. of  $H_2SO_4$ , mixed with 6 pts. of fuming  $H_2SO_4$ , are added to a mixture of 3 pts. of chloral, 8 pts. of naphthalene, and 6 pts. of chloroform (Grabowski, B. 11, 298).

**( $\beta$ )-modification** [156°]. Crystals. Insol. cold, sl. sol. hot, alcohol and ether. Separated from the ( $\alpha$ )-modification by its sparing solubility in alcohol. On distillation it loses  $HCl$  forming dichloro-( $\beta$ )-dinaphthyl-ethylene.

**Tetra-nitro-derivative** [258°]. Yellow powder. Insol. alcohol, ether,  $C_2H_5$ , &c.

**( $\alpha$ )-modification.** Not isolated in the pure state. V. sol. alcohol.

**DI-CHLORO-( $\alpha$ )-DI-NAPHTHYL-ETHYLENE**  $CCl_2CH(C_{10}H_7)_2$ . [150°]. Sl. sol. cold, v. sol. hot, alcohol. Long colourless needles. Less stable than the ( $\beta$ )-modification. Prepared by distilling crude trichloro-( $\alpha$ )-di-naphthyl-ethane with 20 p.c. of lime (Grabowski, B. 11, 299).

**Tetra-nitro-derivative.** [214°].

**Di-chloro-( $\beta$ )-di-naphthyl-ethylene**  $CCl_2CH(C_{10}H_7)_2$ . [219°]. (above 360°). Distils without decomposition. Short prismatic pillars. Sl. sol. alcohol. Prepared by the distillation of tri-chloro-( $\beta$ )-di-naphthyl-ethane.

**Tetra-nitro-derivative.** [293°] (Grabowski, B. 11, 299).

**CHLORO-( $\beta$ )-NAPHTHYL-PHOSPHORIC ACID**  $C_{10}H_7ClOPO(OH)_2$ . [205° uncor.]. Formed as a by-product in the action of  $PCl_5$  (2 mols.) on potassium ( $\beta$ )-naphthol-sulphonate (1 mol.) at 150° (Claus & Zimmermann, B. 14, 1483). Small plates. By boiling alkalis it is decomposed into chloro-( $\beta$ )-naphthol and phosphate.

**CHLORO-NICOTINIC ACID** v. **CHLORO-PYRIDINE-CARBOXYLIC ACID**.

**DI-CHLORO- $\alpha$ -NITRO-ACETOPHENONE**  $C_6H_4(NO_2)CO.CHCl_2$ . [73°]. *Nitro-phenyl dichloro-methyl ketone*. Formed by chlorination of  $C_6H_4(NO_2)CO.Me$  (Gevekoht, A. 221, 828). Plates (from benzoline).

**CHLORO-NITRO-AMIDO-PHENOL**  $C_6H_4ClN_2O_3$ , i.e.  $C_6H_4Cl(NO_2)(NH_2)(OH)$  [2:4:6:1]. [160°]. Formed by reducing chloro-di-nitrophenol [110°] with ammonium sulphide (Griess & Kolbe, A. 109, 286; Faust & Miller, A. 173, 315; Z. 1871, 339; Armstrong, C. J. 25, 14). Slender brass-yellow needles (containing  $\frac{1}{2}$  aq) (from hot water). When dried at 100° it is scarlet. Elimination of  $NH_3$  gives chloro-nitrophenol [110°]— $BHCl$ : yellowish needles.— $BH_2SO_4$ .— $NH_3$  ( $C_6H_4ClN_2O_3$ ).— $Be(C_6H_4ClN_2O_3)_2$ , 4 aq: slender black needles.

**Chloro-nitro-amido-phenol. Methyl ether**  $C_6H_4Cl(NO_2)(OMe)(NH_2)$ . *Chloro-nitro-anis-*

*dine. Acetyl derivative* [185°], yellow needles, sol. alcohol and ether, insol. cold water (Herold, B. 15, 1689).

**Chloro-di-nitro-amido-phenol. Methyl ether**  $C_6H_4Cl(NO_2)_2(OMe)(NH_2)$ . *Acetyl derivative* [165°], yellow needles (H.).

**Chloro-tri-nitro-amido-phenol. Methyl ether**  $C_6H_4Cl(NO_2)_3(OMe)(NH_2)$ . *Acetyl derivative* [198°], orange-yellow needles (H.).

**CHLORO-NITRO-AMIDO-DI-PHENYL-AMINE** v. **CHLORONITROPHENYL-PHENYLENE-DIAMINE**.

**CHLORO-NITRO-ANILINE**  $C_6H_4Cl(NO_2)(NH_2)$  [4:3:1]. [103° uncor.].

**Formation.**—1. By nitration of *p*-chloro-aniline dissolved in 10 pts. of  $H_2SO_4$ ; the yield is 50 p.c. of the chloraniline.—2. Together with a much larger quantity of the (6:3:1)-isomeride by reduction of chloro-di-nitro-benzene  $C_6H_4Cl(NO_2)_2$  [4:3:1] in alcoholic solution with  $SnCl_4$  and  $HCl$ .

**Properties.**—Small yellow glistening needles (from hot petroleum-ether), or long thin needles (from boiling water). V. sol. alcohol, ether and chloroform, m. sol. hot water, nearly insol. cold water. Weak base. By elimination of the  $NH_2$  group it gives *o*-chloro-nitro-benzene [33°]. By replacement of the  $NH_2$  group by  $Cl$ , di-chloro-nitro-benzene [55°] is formed.

**Acetyl derivative**  $C_6H_4Cl(NO_2)(NHAc)$  [100°]; small yellow needles (Claus & Stiebel B. 20, 1379).

**Chloro-nitro-aniline**  $C_6H_4Cl(NO_2)(NH_2)$  [2:4:1]. [105°]. Prepared by heating (1,2,4)-di-chloro-nitro-benzene [43°] with ammonia at 210° (Beilstein & Kurbatoff, A. 182, 98). Appears also to be formed in small quantity by nitrating acetyl-*o*-chloro-aniline. Light yellow needles. Elimination of  $NH_2$  gives *m*-chloro-nitro-benzene.

**Acetyl derivative**  $C_6H_4Cl(NO_2)(NHAc)$ . [139°].

**Chloro-nitro-aniline**  $C_6H_4Cl(NO_2)(NH_2)$  [4:2:1]. [115°]. (B. & K.); [116°] (K.). From (1,4,2)-di-chloro-nitro-benzene and alcoholic  $NH_3$  at 165°. Formed also by nitrating acetyl *p*-chloro-aniline (Körner, G. 4, 373; Beilstein & Kurbatoff, B. 9, 633; A. 182, 94). Orange-yellow needles (from water) or spherical groups of brick-red needles (from alcohol). Elimination of  $NH_2$  gives *m*-chloro-nitro-benzene. Reduction to chloro-phenylene-diamine followed by treatment with sodium-amalgam gives *o*-phenylene-diamine (Körner).

**Chloro-nitro-aniline**  $C_6H_4Cl(NO_2)(NH_2)$  [6:3:1]. [117°].

**Formation.**—1. Together with a smaller quantity of the (4:3:1)-isomeride by reduction of chloro-di-nitro-benzene  $C_6H_4Cl(NO_2)_2$  [4:3:1] in alcoholic solution with  $SnCl_4$  (Claus & Stiebel, B. 20, 1379).—2. By nitration of acetyl-*o*-chloro-aniline (B. & K.).

**Properties.**—Yellow needles. Elimination of  $NH_2$  gives *p*-chloro-nitro-benzene.

**Acetyl derivative**  $C_6H_4Cl(NO_2)(NHAc)$ . [154°].

**Chloro-nitro-aniline**  $C_6H_4Cl(NO_2)(NH_2)$  [3:6:1]. [125°].

**Formation.**—1. By heating (3,6,1)-di-chloro-nitro-benzene [38°] with alcoholic  $NH_3$  for 10 hours at 160° (Körner, G. 4, 373).—2. From

chloro-di-nitro-benzene [89°] and  $\text{NH}_3$  (Laubenheimer, B. 9, 1826).<sup>1</sup>—3. By nitrating acetyl *m*-chloro-aniline (B. a. K.).

**Properties.**—Thin yellow laminae (from alcohol). Elimination of  $\text{NH}_3$  gives *p*-chloro-nitro-benzene. Reduction by tin and  $\text{HCl}$  gives chloro-phenylene-diamine whence sodium-amalgam produces *o*-phenylene-diamine (Körner).

**Acetyl derivative**  $\text{C}_6\text{H}_4\text{Cl}(\text{NO}_2)(\text{NHAc})$ . [115°].

**Chloro-nitro-aniline**  $\text{C}_6\text{H}_4\text{Cl}(\text{NO}_2)(\text{NH}_2)$  [3:4:1]. [157°]. Formed, together with the preceding, by nitrating acetyl *m*-chloro-aniline (B. a. K.). Yellow laminae (from benzene). Elimination of  $\text{NH}_3$  gives *o*-chloro-nitro-benzene [32-5°].

**Acetyl derivative** [142°].

**Chloro-di-nitro-aniline**  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)_2(\text{NH}_2)$  [4:2:6:1]. [145°]. From di-chloro-di-nitro-benzene [104°] and alcoholic  $\text{NH}_3$ . Formed also by chlorinating di-nitro-aniline [138°] and by treating the methyl ether of chloro-di-nitro-phenol [65°] with  $\text{NH}_3$  (Körner). Orange needles. Alcoholic  $\text{KOH}$  converts it into chloro-di-nitro-phenol.

**Di-chloro-nitro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [3:6:2:1]. [98°]. From its acetyl derivative, which is formed, together with the (3,6,4,1)-isomeride [153°], by the nitration of  $\text{C}_6\text{H}_4\text{Cl}_2(\text{NHAc})$  [3:6:1] (Beilstein a. Kurbatow, A. 192, 232). Also from (3,6,2,1)-di-chloro-di-nitro-benzene and alcoholic  $\text{NH}_3$  (Körner). Yellow needles. Displacement of  $\text{NH}_2$  by  $\text{Cl}$  gives (3,6,1,2)-tri-chloro-nitro-benzene [89°].

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NHAc})$ . [205°].

**Di-chloro-nitro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [3:6:6:1]. [79°]. Prepared together with the (3,5,4,1)-isomeride [171°] by nitration of acetyl-(1,3,5)-di-chloro-aniline. Yellow needles. Converted by elimination of  $\text{NH}_3$  into di-chloro-nitro-benzene [33°].

• **Acetyl derivative** [139°]. Sol.  $\text{CS}_2$  (Beilstein a. Kurbatow, B. 11; 1979).

**Di-chloro-nitro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [4:3:2:1]. [96°]. Prepared together with the (4,3,6,1)-isomeride [175°] by nitration of acetyl-(4,3,1)-di-chloro-aniline. Yellow needles.

**Acetyl derivative** [163°] (Beilstein a. Kurbatow, B. 11, 1978).

**Di-chloro-*o*-nitro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [2:4:6:1]. [99°]. Formed by passing chlorine into a solution of *o*-nitraniline in conc.  $\text{HCl}$  (Langer, A. 215, 111). Formed also by nitration of acetyl-(4,2,1)-di-chloro-aniline, or by chlorination of acetyl-(4,2,1)-chloro-nitro-aniline, and decomposition of the resulting acetyl derivative by  $\text{HCl}$  (Witt, B. 7, 1603; 8, 820). Slender orange needles (from benzoline). V. sol. alcohol, ether, or benzoline. Elimination of  $\text{NH}_3$  gives di-chloro-nitro-benzene [65°].

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NHAc})$ . [188°].

**Di-chloro-nitro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [3:6:4:1]. [153°]. Prepared, together with the (3,6,2,1)-isomeride [68°], by nitration of acetyl-(3,6,1)-di-chloro-aniline. Yellow needles.

**Acetyl derivative** [146°] (Beilstein a. Kurbatow, B. 11, 1978; A. 196, 235).

**Di-chloro-nitro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [8:2:6:1]. [168°]. Formed by heating  $\text{C}_6\text{H}_4\text{Cl}_2(\text{NO}_2)$

[58°] with alcoholic  $\text{NH}_3$  at 210° (Beilstein a. Kurbatow, A. 192, 235). By elimination of  $\text{NH}_3$  it gives di-chloro-nitro-benzene [43°].

**Di-chloro-nitro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [3:5:4:1]. [171°]. Large yellow needles. Prepared, together with the (3,5,6,1)-isomeride [79°], by nitration of acetyl-(5,3,1)-di-chloro-aniline. Elimination of  $\text{NH}_3$  gives di-chloro-nitro-benzene [71°].

**Acetyl derivative**. [222°]. Insol. in  $\text{CS}_2$  (Beilstein a. Kurbatow, A. 196, 227; B. 11, 1979).

**Di-chloro-nitro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [3:4:6:1]. [175°]. Prepared by the action of alcoholic  $\text{NH}_3$  on trichloronitrobenzene [58°] or, together with the (3,3,2,1)-isomeride [96°], by the nitration of acetyl-(4,3,1)-di-chloro-aniline. Yellow needles. Displacement of  $\text{NH}_2$  by  $\text{Cl}$  gives tri-chloro-nitro-benzene [58°].

**Acetyl derivative** [124°]. Less sol. alcohol than the isomeride (1,4,5,6) (Beilstein a. Kurbatow, A. 196, 225; B. 11, 1978).

**Di-chloro-nitro-aniline**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [2:6:4:1]. [188°]. Formed by chlorination of *p*-nitro-aniline (Körner, G. 4, 276; Witt, B. 8, 143). Lemon-yellow needles. Elimination of  $\text{NH}_3$  gives di-chloro-nitro-benzene [65°].

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NHAc})$ . [210°].

**Di-chloro-di-nitro-aniline**  $\text{C}_6\text{H}_2\text{Cl}_2(\text{NO}_2)_2(\text{NH}_2)$  [3:4:2:6:1]. [128°]. Formed by nitrating acetyl-(4,3,1)-di-chloro-aniline, and eliminating  $\text{Ac}$  by  $\text{H}_2\text{SO}_4$  (Beilstein a. Kurbatow, A. 196, 235; B. 11, 1978). Large red needles.

**Acetyl derivative**  $\text{C}_6\text{H}_2\text{Cl}_2(\text{NO}_2)_2(\text{NHAc})$ . [246°].

• **Tri-chloro-*m*-nitro-aniline**  $\text{C}_6\text{H}_2\text{Cl}_3(\text{NO}_2)(\text{NH}_2)$  [5:4:2:3:1]. [98°]. From *m*-nitraniline (1 pt.), conc.  $\text{HCl}$  (25 pts.) and water (20 pts.), by passage of a mixture of air and chlorine (Langer, A. 215, 110). Long, broad yellow needles (from light petroleum).

**Tri-chloro-nitro-aniline**  $\text{C}_6\text{H}_2\text{Cl}_3(\text{NO}_2)(\text{NH}_2)$  [2:4:5:6:1]. [124°]. Prepared by nitration of acetyl-tri-chloro-aniline [185°], and elimination of  $\text{Ac}$  by  $\text{HCl}$ . Yellow needles.

**Acetyl derivative**  $\text{C}_6\text{H}_2\text{Cl}_3(\text{NO}_2)(\text{NHAc})$ . [193°] (Beilstein a. Kurbatow, A. 196, 235; B. 11, 1980).

**CHLORO-NITRO-ANISIDINE** v. *Methyl ether of CHLORO-NITRO-AMIDO-PHENOL*.

**CHLORO-NITRO-ANISOL** v. *Methyl ether of CHLORO-NITRO-PHENOL*.

**CHLORO-NITRO-BENZENE**  $\text{C}_6\text{H}_4\text{Cl}(\text{NO}_2)$  [1:2]. Mol. w. 157.4. [32-5°]. (243°). S.G. 24 1-368.

**Formation.**—1. Together with the *p*-isomeride, by nitrating chloro-benzene (Jungfleisch, A. Ch. [4] 15, 186; Laubenheimer, B. 7, 1765; 8, 1621; Sokoloff, Z. 1866, 621; Lesimple, Z. [2] 4, 225). 2. From chloro-nitro-aniline [167°] by elimination of  $\text{NH}_3$  through the diazo-reaction (Beilstein a. Kurbatow, B. 9, 633; A. 182, 107).—3. In small quantity by the action of  $\text{PCl}_5$  on *o*-nitro-phenol (Engelhardt a. Latschinoff, Z. [3] 6, 225).

**Properties.**—Needles; converted by aqueous  $\text{NaOH}$  at 130° into *o*-nitro-phenol. Not attacked by alcoholic  $\text{KOCy}$ .

***m*-Chloro-nitro-benzene**  $\text{C}_6\text{H}_4\text{Cl}(\text{NO}_2)$  [1:3]. [45°]. (286° co $\ell$ ).

**Formation.**—1. By chlorination of nitro-

benzene in presence of iodine (Laubenheimer, *B.* 7, 1766) or  $\text{SbCl}_5$  (Beilstein a. Kurbatoff, *A.* 182, 102).—2. From *m*-nitro-aniline by displacement of  $\text{NH}_2$  by  $\text{Cl}$  through the diazo-reaction (Griess, *Pr.* 13, 381).

**Preparation.**—1. From nitro-benzene (500 g.) and  $\text{FeCl}_3$  (10 g.) by chlorination (Varnholt, *J. pr.* [2] 86, 25).—2. By running a solution of  $\text{NaNO}_2$  into a hot solution of *m*-nitro-aniline and  $\text{Cu}_2\text{Cl}_2$  in dilute  $\text{HCl}$  (Sandmeyer, *B.* 17, 2650).

**Properties.**—Trimetric crystals;  $a:b:c = 561:1:498$ . Sublimes in flat needles. V. sol. ether, benzene, chloroform,  $\text{CS}_2$ ,  $\text{HOAc}$ , and hot alcohol.

**Reactions.**—1. Nitration forms  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)_2$  [39°].—2. Alcoholic  $\text{KOH}$  gives  $(\text{C}_6\text{H}_4\text{Cl})_2\text{N}_2\text{O}$  [97°].—3. Alcoholic  $\text{KCy}$  gives *o*-chloro-benzonitrile (Richter, *B.* 8, 1418).

*p*-Chloro-nitro-benzene  $\text{C}_6\text{H}_4\text{Cl}(\text{NO}_2)$  [1:4]. [88°]. (242°). S.G. 1.33.

**Formation.**—1. Together with the *o*-isomeride, by nitration of chloro-benzene (Riche, *A.* 121, 357; Jungfleisch, *A. Ch.* [4] 15, 186).—2. From *p*-nitro-aniline by displacement of  $\text{NH}_2$  by  $\text{Cl}$  (Griess, *Pr.* 13, 381).—3. From *p*-nitro-phenol and  $\text{PCl}_5$  (Engelhardt a. Latschinoff, *Z.* 1870, 230).—4. From (3,6,1)-chloro-nitro-aniline by elimination of  $\text{NH}_2$  (Beilstein a. Kurbatoff, *A.* 182, 105).

**Properties.**—Trimetric plates.

**Reactions.**—1. Heating with aqueous  $\text{Na}_2\text{CO}_3$  and  $\text{NaOH}$  at  $180^\circ$  slowly forms *p*-nitro-phenol. 2. Alcoholic  $\text{KOH}$  gives  $(\text{C}_6\text{H}_4\text{Cl})_2\text{N}_2\text{O}$  and, at  $180^\circ$ ,  $\text{C}_6\text{H}_4\text{ClN}_2\text{C}_6\text{H}_4\text{Cl}$ . If the alcohol be dilute  $\text{C}_6\text{H}_5\text{ClOEt}$  is formed.—3. Alcoholic  $\text{KCy}$  gives *m*-chloro-benzonitrile.

Chloro-di-nitro-benzene  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)_2$  [1:3:4]. Mol. w. 202. According to Laubenheimer (*B.* 9, 760, 768) the chloro-di-nitro-benzene formed by nitrating *m*-chloro-benzene, exists in four modifications, viz.:

(a). [36°]. Thick monoclinic prisms:  $a:b:c = 1.887:1:981$ ;  $\beta = 114^\circ 14'$ . Gradually passes into the ( $\gamma$ ) modification.

(b). [37°]. Monoclinic prisms,  $a:b:c = 625:1:560$ ;  $\beta = 91^\circ 27'$ . Gradually passes into the ( $\gamma$ ) modification.

(c). [39°]. Thin trimetric needles.

(d). Liquid.

**Reactions.**—1. Aqueous  $\text{NaOH}$  forms chloro-nitro-phenol [89°].—2. Aniline forms  $\text{C}_6\text{H}_4\text{Cl}(\text{NO}_2)(\text{NPhH})$ .—3. Tin and  $\text{HCl}$  reduce it to chloro-phenylene-diamine [72°].—4. Boiled with a solution of sodium sulphite it gives chloro-nitro-benzene-sulphonic acid and  $\text{NaNO}_2$  (Laubenheimer, *B.* 16, 597).—5. Phenyl-hydrazine forms  $\text{C}_6\text{H}_4\text{Cl}(\text{NO}_2)\text{N}_2\text{H}_5\text{Ph}$  [140°] (Willgerodt, *J. pr.* [2] 87, 355).

Chloro-di-nitro-benzene  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)_2$  [1:2:4]. [53-5°]. (315°). S.G. 1.697.

**Formation.**—1. By nitration of *o*- or *p*-chloro-nitro-benzene (Jungfleisch, *A. Ch.* [4] 15, 186).—2. From di-nitro-phenol and  $\text{PCl}_5$  (Clemm, *Z.* 1870, 274).

**Properties.**—Trimetric crystals; v. sol. cold alcohol, v. sol. boiling alcohol and ether. Jungfleisch describes a physical isomeride [42°].

**Reactions.**—1. Tin and  $\text{HCl}$  form chloro-nitro-aniline [89°].—2. Strong aqueous  $\text{KOH}$  forms di-nitro-phenol.—3. Alcoholic  $\text{NH}_3$  at

$110^\circ$  forms di-nitro-aniline [175°].—4. Alcoholic  $\text{NMe}_3$  forms  $\text{C}_6\text{H}_3(\text{NO}_2)_2(\text{NMe}_3)$  [78°].—5. Dimethyl-aniline gives  $\text{C}_6\text{H}_3(\text{NO}_2)_2(\text{NPhMe})$  [187°] (Leymann, *B.* 15, 1233).—6. By the action of  $\text{KOH}$  dissolved in an alcohol, it gives the ether of the di-nitro-phenol corresponding to the alcohol used (Willgerodt, *B.* 12, 762).—7. Phenyl-hydrazine in the cold forms  $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{N}_2\text{H}_5\text{Ph}$  [120°] crystallising in red plates and converted by boiling  $\text{HOAc}$  into  $\text{C}_6\text{H}_3(\text{NO}_2)_2\text{N}_2\text{H}_5\text{Ph}$  [247°] (Willgerodt, *J. pr.* [2] 87, 347, 449).

Chloro-tri-nitro-benzene  $\text{C}_6\text{H}_2\text{Cl}(\text{NO}_2)_3$  [1:2:4:6]. Picryl chloride. Mol. w. 247. [83°]. From tri-nitro-phenol (picric acid) and  $\text{PCl}_5$  (Pisani, *A.* 92, 326; Clemm, *J. pr.* [2] 1, 145; *Z.* [2] 6, 444). Amber-yellow monoclinic tables (from ether) or nearly colourless needles (from alcohol). V. sol. boiling alcohol, sl. sol. ether. Combines with benzene and other aromatic hydrocarbons (Liebermann a. Palm, *B.* 8, 378).

**Reactions.**—1. Water or aqueous  $\text{Na}_2\text{CO}_3$  converts it into tri-nitro-phenol.—2. Ammonia forms tri-nitro-aniline.—3. Alcoholic  $\text{KOH}$  forms  $\text{C}_6\text{H}_2(\text{NO}_2)_3\text{OEt}$ .—4. Ethyl-hydrazine forms  $\text{C}_6\text{H}_2(\text{NO}_2)_3\text{N}_2\text{H}_5\text{Et}$  [200°] (Fischer, *A.* 199, 299).—5. Phenyl-hydrazine forms  $\text{C}_6\text{H}_2(\text{NO}_2)_3\text{N}_2\text{H}_5\text{Ph}$  [225°] (238°) (Willgerodt, *J. pr.* [2] 87, 357).—6. Alcoholic di-methyl-aniline gives rise to  $\text{C}_6\text{H}_2(\text{NO}_2)_3\text{NMe}_2$  [114°] (Van Romburgh, *Z. T. C.* 2, 105).

Di-chloro-nitro-benzene  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)$  [1:3:4]. [33°]. Formed by nitrating *m*-di-chloro-benzene (Körner, *G.* 4, 305; *J.* 1875, 323; Beilstein a. Kurbatoff, *A.* 182, 97). Long needles (from alcohol). Converted by alcoholic  $\text{NH}_3$  at  $210^\circ$  into  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)(\text{NO}_2)$  [1:3:4] [125°]. Aqueous  $\text{Na}_2\text{CO}_3$  has no action even at  $200^\circ$ . Alcoholic  $\text{NaOH}$  readily forms  $\text{C}_6\text{H}_3\text{Cl}_2(\text{OEt})(\text{NO}_2)$ .

Di-chloro-nitro-benzene  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)$  [1:2:4]. [43°]. From  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [1:2:4:3] and [6:2:4:3] by displacement of  $\text{NH}_2$  by  $\text{H}$  (Beilstein a. Kurbatoff, *A.* 192, 235). Formed also by nitration of *o*-di-chloro-benzene (B. a. K., *A.* 176, 41). Long needles (from alcohol). Converted by alcoholic ammonia at  $210^\circ$  into  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NH}_2)(\text{NO}_2)$  [105°].

Di-chloro-nitro-benzene  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)$  [1:4:6]. [55°]. (266°). S.G. 1.669.

**Formation.**—1. By passing chlorine into cold nitro-benzene (75 g.) containing  $\text{FeCl}_3$  (11.5 g.) (B. a. K.; Page, *A.* 225, 208).—2. By nitration of *p*-di-chloro-benzene (Jungfleisch).—3. From  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)(\text{NH}_2)$  [4:3:1] by the action of  $\text{Cu}_2\text{Cl}_2$  upon the diazo-compound (Claus a. Stiebel, *B.* 20, 1391).

**Properties.**—Triclinic crystals (from  $\text{CS}_2$ ). Volatile with steam. Alcoholic  $\text{KOH}$  converts it into  $\text{C}_6\text{H}_3(\text{OH})\text{Cl}(\text{NO}_2)$  [4:4:6] [86°], together with  $(\text{C}_6\text{H}_3\text{Cl}_2)_2\text{N}_2\text{O}$  and di-chloro-aniline [60°] (Laubenheimer, *B.* 7, 1600). By alcoholic  $\text{NH}_3$  at  $200^\circ$  it is converted into chloro-nitro-aniline [115°].

Di-chloro-nitro-benzene  $\text{C}_6\text{H}_3\text{Cl}_2(\text{NO}_2)$  [1:3:5]. [65°]. From the di-chloro-nitro-anilines  $\text{C}_6\text{H}_3(\text{NH}_2)\text{Cl}_2(\text{NO}_2)$  [1:2:4:6] and [1:2:6:4] by eliminating  $\text{NH}_3$  (Körner, *G.* 4, 376; Witt, *B.* 7, 1604; *B.* 8, 144). Long thin laminae (from alcohol). Volatile with steam. Alcoholic  $\text{NH}_3$  does not act upon it.

Di-chloro-di-nitro-benzene  $\text{C}_6\text{H}_2\text{Cl}_2(\text{NO}_2)_2$  [103°]. Formed by nitrating *m*-di-chloro-

benzene (Körner, *G.* 4, 305; *J.* 1875, 323). Yellowish prisms. Converted by aqueous KOH into a chloro-di-nitro-phenol.

Di-chloro-di-nitro-benzene  $C_6H_2Cl_2(NO_2)_2$  [1:4:2:6]. [878] (*J.*); [104°] (Engelhardt & Latschinoff). (812°). S.G.  $\frac{12}{1}$  1.710. Formed, together with the following, by nitrating *p*-dichloro-benzene (Jungfleisch). Small monoclinic plates. Boiling aqueous  $Na_2CO_3$  converts it into di-chloro-phenol [80°].

Di-chloro-di-nitro-benzene  $C_6H_2Cl_2(NO_2)_2$  [1:4:2:3 or 5] [107°] (*J.*); [101°] (E. a. L.). (318°). S.G.  $\frac{12}{1}$  1.695. Formed as above. Monoclinic needles. Boiling aqueous  $Na_2CO_3$  converts it into chloro-di-nitro-phenol [70°]. Alcoholic  $NH_3$  at 140° forms  $C_6H_2Cl_2(NH_2)(NO_2)$  [66°] (Körner, *G.* 4, 350).

Tri-chloro-nitro-benzene  $C_6H_3Cl_3(NO_2)$  [1:2:4:5]. (288°). S.G.  $\frac{22}{1}$  1.790. Formed by nitrating  $C_6H_3Cl_3$  [1:2:4] (Lesimple, *B.* [2] 6, 161; *A.* 137, 123). Sulphur-yellow monoclinic prisms (from  $CS_2$ ). Converted by  $NH_3$  into  $C_6H_3(NH_2)Cl_2(NO_2)$  [1:3:4:6].

Tri-chloro-nitro-benzene  $C_6H_3Cl_3(NO_2)$  [1:2:3:4]. [56°]. From *c*-trichloro-benzene and fuming  $HNO_3$  (Beilstein & Kurbatow, *A.* 192, 235). Colourless silky needles (from alcohol). V. sol. ether and  $CS_2$ , m. sol. dilute (50 per cent.) acetic acid, sl. sol. alcohol. May be reduced to tri-chloro-aniline [68°]. Alcoholic  $NH_3$  forms  $C_6H_3Cl_2(NH_2)(NO_2)$  [1:2:3:4] [163°].

Tri-chloro-nitro-benzene  $C_6H_3Cl_3(NO_2)$  [1:3:5:2]. [68°]. From *s*-trichloro-benzene and fuming  $HNO_3$  (Beilstein & Kurbatow, *A.* 192, 233). Long needles (from alcohol). V. sol.  $CS_2$  and light petroleum. Ammonia at 230° forms  $C_6H_3(NH_2)Cl_2(NO_2)$  [1:3:5:2].

Tri-chloro-nitro-benzene  $C_6H_3Cl_3(NO_2)$  [1:3:6:2]. [89°]. Formed from  $C_6H_3Cl_3(NH_2)(NO_2)$  [3:6:1:2] by diazo-reaction (B. a. K.). Colourless needles (from light petroleum). V. sol. alcohol, less sol. light petroleum.

Tri-chloro-di-nitro-benzene  $C_6H_2Cl_3(NO_2)_2$  [103:5°]. (335°). S.G.  $\frac{22}{1}$  1.85. Formed by nitration of *u*-tri-chloro-benzene (Jungfleisch). Light yellow six-sided prisms. Insol. cold alcohol, sol. hot alcohol and ether.

Tri-chloro-di-nitro-benzene  $C_6H_2Cl_3(NO_2)_2$  [1:3:5:2:4]. [130°]. Formed by nitrating *s*-trichloro-benzene (Jackson & Wing, *Am.* 9, 353). Thick white prisms (from alcohol). Sol. cold alcohol and ether; v. sol. benzene,  $CS_2$ , and chloroform.

Tri-chloro-tri-nitro-benzene  $C_6Cl_3(NO_2)_3$  [1:3:5:2:4:6]. [187°]. Formed by nitrating the preceding (Jackson & Wing, *Am.* 9, 354). Thick white needles (from alcohol). V. sl. sol. water, sol. alcohol, v. sol. ether, benzene, and  $CS_2$ .

Tetra-chloro-nitro-benzene  $C_6H(NO_2)Cl_4$  [1:2:3:4:5]. [22°]. From *u*-tetra-chloro-benzene and fuming  $HNO_3$  (Beilstein & Kurbatow, *A.* 192, 238). Colourless needles. V. sol. benzene,  $CS_2$ , and hot alcohol.

Tetra-chloro-nitro-benzene  $C_6HCl(NO_2)$  [1:2:3:4:5]. [64:6°]. From *c*-tetra-chloro-benzene and fuming  $HNO_3$  (Beilstein & Kurbatow, *A.* 192, 239). Small needles, sl. sol. alcohol.

#### Tetra-chloro-nitro-benzene

$C_6H(NO_2)Cl_4$  [1:2:3:5:6]. [99°]. (304°). S.G.  $\frac{12}{1}$  1.744. From *s*- $C_6H_2Cl_4$  and fuming  $HNO_3$ . Some chloranil is also formed, but light petroleum dissolves the  $C_6H(NO_2)Cl_4$  only (Beilstein & Kurbatow, *A.* 192, 236; cf. Jungfleisch, *loc. cit.*). Formed also by passing chlorine at 100° into nitro-benzene containing  $FeCl_3$  (Page, *A.* 225, 208)? Needles (from alcohol).

Penta-chloro-nitro-benzene  $C_6Cl_5(NO_2)$  [146°]. (328°). S.G.  $\frac{22}{1}$  1.718. Formed by heating penta-chloro-benzene with fuming  $HNO_3$  (Jungfleisch). Slender needles (from alcohol) or monoclinic tables (from  $CS_2$ ). V. sol. boiling alcohol,  $CS_2$ , and chloroform.

CHLORO-NITRO-BENZENE-SULPHONIC ACID  $C_6H_3Cl(NO_2)SO_3H$  [1:4:3]. Formed by boiling (1:3:4)-chloro-di-nitro-benzene with a solution of sodic sulphite.— $NaA'$  2aq: glistening prisms or needles, sol. water and alcohol.

Amide [159°]. Plates or needles. Sol. alc(oh), sl. sol. water (Laubenheimer, *B.* 15, 597).

*m*-Chlor-nitro-benzene sulphonic acid  $C_6H_3Cl(NO_2)(SO_3H)$  [1:3:2]. Prepared by sulphonation of *m*-chloro-nitro-benzene. On reduction it gives a chloro-amido-phenyl-mercaptan which does not form anhydro-compounds.

Salts.— $A'$  2aq: white sparingly soluble needles.— $A'$  1Pb\*: soluble needles.— $A'K$ : white soluble needles (Allert, *B.* 14, 1434).

(*a*)-Chloro-nitro-benzene-sulphonic acid  $C_6H_3Cl(NO_2)SO_3H$  [1:3:2]. Formed together with an isomeric (*β*)-acid by sulphonation of *m*-chloro-nitro-benzene.

Salts.— $A'K$ : needles or plates, sol. alcohol.  $A'Na$  2aq: yellow needles.— $A'Ba$  2aq: small brown needles or plates, v. sol. alcohol.— $A'Sr$  1aq: thick brown plates, sol. alcohol (Post & Meyer, *B.* 14, 1606).

(*β*)-Chloro-nitro-benzene-sulphonic acid  $C_6H_3Cl(NO_2)SO_3H$  [1:3:2]. Formed together with the preceding by sulphonation of *m*-chloro-nitro-benzene.

Salts.— $A'K$  1aq: light yellow prisms.— $A'Ba$  1aq: small yellow needles, insol. alcohol.— $A'Sr$ : yellow crystalline powder (Post & Meyer, *B.* 14, 1606).

*m*-Chloro-nitro-benzene-di-sulphonic acid  $C_6H_2Cl(NO_2)(SO_3H)_2$  [1:3:2:2]. Prepared by sulphonating *m*-chloro-nitro-benzene with boiling  $H_2SO_4$ .— $A''K$ : pearly scales (Allert, *B.* 14, 1436).

#### CHLORO-NITRO-BENZOIC ACID

$C_6H_2Cl(NO_2)(CO_2H)$  [2:4:1]. [137°]. Formed by oxidising chloro-nitro-toluene [65°] by alkaline  $KMnO_4$  (Wachendorff, *A.* 185, 275; Lellmann, *B.* 17, 534).

##### Chloro-nitro-benzoic acid

$C_6H_2Cl(NO_2)(CO_2H)$  [2:4:1]. [137°]. Formed by the action of  $H_2SO_4$  and  $HNO_3$  on the di-chloro-benzoic acid [156°] obtained by direct chlorination of benzoic acid (Claus & Bücher, *B.* 20, 1624). Either this or the following acid ought to be identical with the isomeric [235°].

##### Chloro-nitro-benzoic acid

$C_6H_2Cl(NO_2)(CO_2H)$  [3:4:1]. [136°]. Obtained by the action of  $H_2SO_4$  and  $HNO_3$  on the di-chloro-benzoic acid [201°] formed by chlorination of benzoic acid (C. a. B.).— $BaA'$  4aq (B. a. K.).

##### (*β*)-Chloro-nitro-benzoic acid

$C_6H_2Cl(NO_2)(CO_2H)$  [3:6:1]. [188°]. One of the

products of the nitration of *m*-chloro-benzoic acid (Ulrich, A. 222, 97).

Salts.—BaA', 4aq.—CaA', 4aq.—PbA',—KA' 2½aq.

Ethyl ether EtA'. [282°] (Cunzeo a. Hübner, A. 135, 113).

Anilide  $C_6H_5Cl(NO_2)(CONPhH)$ : [164°]; needles.

Chloro-nitro-benzoic acid

$C_6H_4Cl(NO_2)CO_2H$  [4:2:1]. [189°]. From  $C_6H_4Cl(NO_2)Me$  [4:2:1] by oxidation with  $HNO_3$  (S.G. 1:1) (Varnholt, J. pr. [2] 86, 30). Formed also by saponifying its nitrile with dilute  $H_2SO_4$ . Long needles; sl. sol. cold water and  $CS_2$ , m. sol. chloroform.

Nitrile  $C_6H_4Cl(NO_2)CN$ . [98°]. From the corresponding chloro-nitro-aniline by Sandmeyer's reaction (Claus, J. pr. [2] 37, 197). Needles, v. sol. ether and alcohol, m. sol. cold water.

Chloro-nitro-benzoic acid

$C_6H_4Cl(NO_2)CO_2H$  [1:3:5]. [147°]. From  $C_6H_5(NH_2)(NO_2)CO_2H$ , conc.  $HCl$ , and nitrous acid gas (Hübner, A. 222, 89). Small needles. V. sol. alcohol, ether and glacial acetic acid.

Salts.—BaA', 4aq.—PbA'.

Chloro-nitro-benzoic acid  $C_6H_4Cl(NO_2)CO_2H$  [2:5:1]. [164°]. S. 361 at 15°. Formed by nitration of *o*-chloro-benzoic acid (Wilkins a. Rack, A. 222, 195; cf. Kekulé, A. 117, 153). Formed also by the action of  $PCl_5$  on nitro-*o*-oxy-benzoic acid (Hübner, Z. [2] 2, 614). Long thin monoclinic needles (from dilute  $HCl$ ). V. sol. hot water, sl. sol. cold water, v. e. sol. alcohol, ether and benzene.

Salts.—NH<sub>4</sub>A'.—NaA'.—BaA', 3aq.—SrA', ½aq.—CaA', 2aq.—ZnA', 5½aq.—CdA', 5aq.—PbA'.

Ethyl ether EtA'. [29°].

Nitrile  $C_6H_4Cl(NO_2)CN$ . [106°]. Formed by nitrating the nitrile of *o*-chloro-benzoic acid (Henry, B. 2, 438).

Chloro-nitro-benzoic acid  $C_6H_4Cl(NO_2)CO_2H$  [4:3:1]. [180°]. Formed by nitration of *p*-chloro-benzoic acid (Reveill, A. 222, 182). Formed also by oxidizing the corresponding chloro-nitro-toluene (Hübner, Z. [2] 2, 614).

Salts.—BaA', 4aq.—CaA', 5½aq.—MgA', 5aq. Ethyl ether EtA'. [59°].

Anilide  $C_6H_4Cl(NO_2)CONPhH$ . [131°].

Nitrile  $C_6H_4Cl(NO_2)CN$ . [101°]. From the corresponding chloro-nitro-aniline by Sandmeyer's reaction with cuprous cyanide (Claus, J. pr. [2] 37, 197). Needles, sl. sol. cold water.

Chloro-nitro-benzoic acid  $C_6H_4Cl(NO_2)CO_2H$  [3:4:1]. [186°]. From the nitrile by saponification with dilute  $H_2SO_4$  (Claus, J. pr. [2] 37, 200). White needles. V. sol. hot water, alcohol, ether, chloroform, sl. sol. cold water,  $CS_2$ .—Salts.—BaA', 2aq.—CaA', 2aq.—MgA': needles (from water).

Nitrile  $C_6H_4Cl(NO_2)CN$ . [87°]. From the corresponding chloro-nitro-aniline by displacement of  $NH_2$  by  $Cy$ . Colourless needles, sl. sol. cold, v. sol. hot, water.

(a) Chloro-nitro-benzoic acid

$C_6H_4Cl(NO_2)(CO_2H)$  [3:2:1]. [235°]. From *m*-chloro-benzoic acid and fuming  $HNO_3$ . Separated by water from the more soluble (*β*)-isomeride [187°] (Ulrich, A. 222, 95). Long thin needles,

or six-sided tables. V. sl. sol. water, v. sol. ether.

Salts.—BaA', 4aq.—CaA', 3aq.

Anilide  $C_6H_4Cl(NO_2)(CONPhH)$ . [186°].

Chloro-di-nitro-benzoic acid\*

$C_6H_2Cl(NO_2)_2CO_2H$  [2:(3 or 5):3:1]. [238°]. By nitration of *o*-chloro-benzoic acid (Wilkins a. Rack, A. 222, 201). Small colourless needles (from petroleum). V. sol. water, alcohol, ether, or petroleum, sl. sol. benzene.

Di-chloro-nitro-benzoic acid

$C_6H_3Cl_2(NO_2)(CO_2H)$  [4:3:2:1]. [560°]. Obtained by nitration of (4,3,1)-di-chloro-benzoic acid [201°], which is formed by direct chlorination of benzoic acid (Claus a. Bücher, B. 20, 1621). Small needles. Sol. water.

Di-chloro-nitro-benzoic acid

$C_6H_3Cl_2(NO_2)(CO_2H)$  [3:2:2:1]. [215°]. Prepared by nitrating (3,2,1)-di-chloro-benzoic acid [156°], which is got by chlorinating benzoic acid (Claus a. Bücher, B. 20, 1621). Sl. sol. boiling water.—BaA', 4aq: lens-shaped aggregates of small needles.

Tri-chloro-nitro-benzoic acid

$C_6H_2Cl_3(NO_2)(CO_2H)$  [2:4:6:3:1]. [220°]. From  $C_6H_5Cl_2(CO_2H)$  [2:4:6:1] by nitration (Beilstein a. Kuhlberg, A. 152, 239). Small needles (from water). V. sl. sol. boiling water.—CaA', ½aq.—BaA', 2aq: crystalline powder.

Tetra-chloro-nitro-benzoic acid

$C_6Cl_4(NO_2)CO_2H$  [5:4:3:2:6:1]. Formed by nitration of tetra-chloro-benzoic acid [5:4:3:2:1], by a mixture of fuming  $HNO_3$  and conc.  $H_2SO_4$ . Silvery plates. Sol. water. By tin and  $HCl$  it is reduced to tetra-chloro-amido-benzoic acid.

Salts.—A', Ba 2aq: v. sol. water, small colourless needles.—A', Ca: easily soluble glistening plates (Tust, B. 20, 2441).

CHLORO-NITRO-BENZOIC ALDEHYDE

$C_6H_4Cl(NO_2)CHO$  [3:4:1]. [62°]. From (3,4,1)-chloro-nitro-toluene by chlorinating and treating the resulting  $C_6H_4Cl(NO_2)CH_2Cl$  with lead or copper nitrate solution (Landsberg, D. P. J. 262, 139). White needles (from water).

Di-chloro-*o*-nitro-benzoic aldehyde

$C_6H_3Cl_2(NO_2)CHO$ . [138°]. Obtained by nitration of di-chloro-benzoic aldehyde with a mixture of  $HNO_3$  and  $H_2SO_4$  (Gnehm, B. 17, 753). Pearly plates or needles. By treatment with acetone and  $NaOH$  it yields tetra-chloro-indigo.

CHLORO-NITRO-CAMPHOR o. САНФОР.

α-CHLORO-*p*-NITRO-CINNAMIC ACID

$C_6H_4(NO_2)CH:CHCl.CO_2H$ . [224°]. From α-chloro-*p*-nitro-β-oxy-β-phenyl-propionic acid and  $HCl$  (S.G. 1:1) at 180° (Lipp, B. 19, 2646). Prisms (from alcohol).

CHLORO-DI-NITRO-CYMENE

$C_6HCl(NO_2)_2(CH_3)(C_2H_5)$  [2:2:2:1:4]. [109°]. Monoclinic prisms. Prepared by nitration of chloro-cymene [214°] (Gerichten, B. 11, 1091).

Chloro-di-nitro-cymene

$C_6HCl(NO_2)_2(CH_3)(C_2H_5)$  [3:2:2:1:4]. [101°]. From di-nitro-thymol and  $PCl_5$  (Ladenburg a. Engelbrecht, B. 10, 1220). Light yellow prisms.

α-Di-chloro-nitro-cymene

$C_6H_2(CHCl)_2(NO_2)(C_2H_5)$  [1:3:4]. From nitro-cuminic aldehyde  $C_6H_4(CHO)(NO_2)(C_2H_5)$  and  $PCl_5$  (Widmann, B. 15, 167). Oil.

CHLORO-DI-NITRO-ETHANE  $C_2H_4Cl(NO_2)_2$ ?  
A liquid formed when ethyldene chloride is

heated in a sealed tube with  $\text{HNO}_3$  at  $100^\circ$  (Lauterbach, *B.* 12, 677).

**Tetra-chloro-di-nitro-ethane**  $\text{C}_2\text{Cl}_4\text{N}_2\text{O}_4$ . Formed by direct union of tetra-chloro-ethylene with nitric peroxide (Hoch & Kolbe, *J. pr.* [2] 4, 50). Feathery needles (from alcohol); insol. water. Volatile with steam. Decomposes at  $140^\circ$ . Aqueous KOH forms long prisms of  $\text{C}_2\text{Cl}_4(\text{NO}_2)_2(\text{OK})$ .

**CHLORO-NITRO-ETHYL-ANILINE**  $\text{C}_6\text{H}_4\text{ClN}_2\text{O}_4$ , i.e.  $\text{C}_6\text{H}_4\text{Cl}(\text{NO}_2)\text{NH}_2$  [5:2:1]. [ $84^\circ$ ]. From chloro-di-nitro-benzene and an alcoholic solution of ethyl-aniline (Laubenheimer, *B.* 11, 1156). Golden needles; sl. sol. cold alcohol.

**DI-CHLORO-NITRO-ETHYL-BENZENE**  $\text{C}_6\text{H}_4\text{Cl}_2\text{N}_2\text{O}_4$ . [30°]. Formed by the union of Cl with  $\text{C}_6\text{H}_4\text{ClCH}_2\text{CH}_2\text{NO}_2$  (Priebs, *A.* 225, 344). Usually an oil. Volatile with steam. Aqueous NaOH forms  $\text{C}_6\text{H}_4\text{Cl}_2\text{CH}_2\text{CH}_2\text{NO}_2$ .

**Di-chloro-nitro-ethyl-benzene**  $\text{C}_6\text{H}_4\text{Cl}_2(\text{NO}_2)_2$  [Et 1:4:2:2]. [ $175^\circ$ ]. Formed by boiling di-chloro-ethyl-benzene with  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  for 50 hours (Istrati, *B.* [2] 48, 41). Crystalline plates, sol. hot water. Gives a yellowish-white pp. with  $\text{FeCl}_3$ .

**Di-chloro-tri-nitro-ethyl-benzene**  $\text{C}_6\text{Cl}_3(\text{NO}_2)_3$  [Et. [ $195^\circ$ ]. Formed at the same time as the preceding (Istrati). Groups of small crystals; insol. water, v. sol. alcohol.  $\text{FeCl}_3$  pps. its alcoholic solution.

**Tetra-chloro-nitro-ethyl-benzene**  $\text{C}_6\text{Cl}_4(\text{NO}_2)_2(\text{C}_2\text{H}_5)$  [1:3:4:5:2:6]. [ $30^\circ$ ]. Formed by passing  $\text{C}_2\text{H}_5$  into a mixture of  $\text{AlCl}_3$  and  $\text{C}_6\text{H}_4\text{Cl}_2(\text{NO}_2)_2$  (Istrati, *A. Ch.* [6] 6, 498). Gelatinous solid, v. sol. ether and  $\text{CHCl}_3$ . Decomposes on distillation, giving tetra-chloro-di-ethyl-benzene.

**TRI-CHLORO-NITRO-ETHYLENE**  $\text{C}_2\text{Cl}_3\text{N}_2\text{O}_4$  (?) Formed by adding  $\text{C}_2\text{Cl}_4$  to a cooled mixture of  $\text{H}_2\text{SO}_4$  and fuming  $\text{HNO}_3$  (Hoch, *J. pr.* [2] 6, 95). Pungent yellow oil; decomposed by water and alkalis. Br at  $150^\circ$  converts it into  $\text{C}_2\text{Cl}_3\text{Br}_2(\text{NO}_2)_2$  [ $\approx 120^\circ$ ]. Liquid nitric peroxide at  $115^\circ$  forms feathery crystals of an unstable compound  $\text{C}_2\text{Cl}_3(\text{NO}_2)_2$ .

**CHLORO-NITRO-MESITYLENE**  $\text{C}_6\text{H}_3\text{ClNO}_2$ , i.e.  $\text{C}_6\text{HCl}(\text{NO}_2)\text{Me}_2$  [2:4:1:3:5]. [ $57^\circ$ ]. Formed by nitrating chloro-mesitylene (Fittig & Hoogewerff, *A.* 150, 324; *Z.* [2] 5, 168). Pale yellow spicular crystals, v. sol. alcohol.

**Chloro-di-nitro-mesitylene**  $\text{C}_6\text{Cl}(\text{NO}_2)_2\text{Me}_2$ . [ $179^\circ$ ]. The chief product of the action of fuming  $\text{HNO}_3$  on chloro-mesitylene (F. & H.). Long colourless needles (from alcohol). Sl. sol. cold alcohol. May be sublimed.

**CHLORO-NITRO-METHANE**  $\text{CH}_3\text{Cl}(\text{NO}_2)$ . [ $123^\circ$ ]. S.G. is 1.466. Formed by the action of chlorine-water on sodium nitro-methane:  $\text{CH}_3\text{Na}(\text{NO}_2) + \text{Cl}_2 = \text{NaCl} + \text{CH}_3\text{Cl}(\text{NO}_2)$ . The presence of Cl and the chlorous nitroxyl ( $\text{NO}_2$ ) render the hydrogen displaceable by sodium; hence the liquid dissolves in alkali.

**Chloro-di-nitro-methane**  $\text{CCl}_2(\text{NO}_2)_2$ . Potassium salt  $\text{CKCl}(\text{NO}_2)_2$ : large yellow crystals, sol. water, explodes at  $145^\circ$  (Losanitsch, *B.* 17, 849).

**Di-chloro-di-nitro-methane**  $\text{CCl}_2(\text{NO}_2)_2$  (above  $100^\circ$ ). S.G. is 1.685 (M.). Formed by passing chlorine into an aqueous solution of  $\text{CKCl}(\text{NO}_2)_2$  (Losanitsch, *B.* 17, 848).

**Preparation.**—Crude naphthalene tetrachlor-

ide (200 grms.) is treated with fuming  $\text{HNO}_3$  (400 c.c.) in a large retort; when the reaction is over, the mixture is distilled as long as the residue in the retort froths strongly. The distillate is diluted with twice its bulk of water and the di-chloro-di-nitro-methane distilled off with steam; the yield is 4 p.c. of the naphthalene tetrachloride (Marignac, *A.* 88, 16; Raschig, *B.* 18, 3326).

**Properties.**—Pungent oil: volatile with steam. On reduction with  $\text{SnCl}_2$  it yields hydroxylamine.

**Tri-chloro-nitro-methane**  $\text{CCl}_3(\text{NO}_2)$ . *Chloro-picric*. *Nitro-chloroform*. Mol. w. 164.3. [ $112^\circ$  cor.]. S.G.  $\frac{4}{5}$  1.6923 (Thorpe). C.E. ( $0^\circ$ - $10^\circ$ ) .001106; ( $0^\circ$ - $100^\circ$ ) .0012256. S. (alcohol of 80.5 p.c.) .743 (Cossa, *G.* 2, 181). S.V. 110.49.  $\mu$ , 1.4670 (Gladstone, *C.* J. 23, 101).

**Formation.**—1. By distilling picric acid and other nitro-compounds with bleaching-powder (Stenhouse, *A.* 66, 241; *P. M.* [3] 33, 53; Gerhardt & Cahours, *Compt. chim.* 1849, 34, 170).—2. By distilling chloral with conc.  $\text{HNO}_3$  (Kekulé, *A.* 106, 144).—3. From chloroform and  $\text{HNO}_3$  (Mills, *C. J.* 24, 641).—4. By distilling alcohol with sodic chloride,  $\text{KNO}_3$ , and  $\text{H}_2\text{SO}_4$  (Kekulé, *A.* 101, 212).

**Preparation.**—A saturated (at  $80^\circ$ ) solution of picric acid (1 pt.) is mixed with bleaching powder (10 pts.) previously made into paste with water, and the mixture distilled (Hofmann, *A.* 139, 111).

**Properties.**—Pungent liquid. V. sl. sol. water, v. sol. alcohol and ether.

**Reactions.**—1. May be reduced by iron and acetic acid to methylamine (Geisse, *A.* 109, 282). 2. Fuming HI at  $100^\circ$  forms  $\text{NH}_3$ ,  $\text{HCl}$ , and  $\text{CO}_2$  (Mills, *C. J.* 17, 153).—3.  $\text{NaOEt}$  in absolute alcohol gives orthocarbonic ether  $\text{C}(\text{OEt})_3$  (Bassett, *C. J.* 17, 193).—4.  $\text{KC}_2\text{O}_7$  and dilute alcohol forms chloro-nitro-malonitrile  $\text{C}(\text{NO}_2)\text{ClC}_2\text{O}_7$ , an unstable compound which gives with aqueous lead acetate a pp.  $\text{C}(\text{NO}_2)\text{ClC}_2\text{O}_7 \cdot 3\text{PbO}$  and with silver nitrate  $\text{C}(\text{NO}_2)\text{ClC}_2\text{O}_7 \cdot (\text{AgNO}_3)_8\text{aq}$  (Bassett, *C. J.* 19, 352).—5. Alcoholic ammonia forms guanidine  $\text{C}(\text{NH})(\text{NH}_2)_3$  (Hofmann, *C. J.* 19, 249).—6. Alcoholic KOH gives  $\text{KCl}$  and  $\text{KNO}_3$  (S.).—7. Alcoholic KOAc at  $100^\circ$  gives  $\text{KCl}$ ,  $\text{K}_2\text{CO}_3$ , and  $\text{KNO}_3$  (Bassett, *C. J.* 18, 31).—8.  $\text{K}_2\text{SO}_4$  forms  $\text{CH}(\text{NO}_2)(\text{SO}_4\text{K})_2$  (Rathke, *A.* 161, 149).—9. With benzene in presence of  $\text{Al}_2\text{Cl}_3$  it yields tri-phenyl-carbinol and tri-phenyl-methane (Elbs, *B.* 18, 1274).—10. With phenol and  $\text{Al}_2\text{Cl}_3$  the chief product is aurin (tri-oxy-tri-phenyl-carbinol) (E.).—11. With naphthalene and  $\text{Al}_2\text{Cl}_3$  it yields tri-naphthyl-carbinol (E.).

**DI-CHLORO-NITRO-TETRA-METHYL-DI-AMIDO-TRI-PHENYL-METHANE**

$\text{C}_6\text{H}_4\text{N}_4\text{Cl}_2\text{O}_4$ , i.e.  $\text{C}_6\text{H}_4(\text{NO}_2)_2\text{CH}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ . [ $208^\circ$ ]. Formed from *m*-chloro-di-methyl-aniline, *p*-nitro-benzaldehyde,  $\text{ZnCl}_2$ , and  $\text{HCl}$  (Kock, *B.* 20, 1562). Lemon-yellow scales (from benzene). May be reduced to  $\text{C}_{12}\text{H}_{12}\text{N}_4\text{Cl}_2$  [ $181^\circ$ ]. Picrate  $\text{C}_{12}\text{H}_{12}\text{N}_4\text{O}_4\text{Cl}_2$  [ $189^\circ$ ].

**CHLORO-NITRO-DI-METHYL-ANILINE**  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{NMe}_2)$  [4:3:1]. [ $56^\circ$ ]. Formed together with other products by the action of nitrous acid upon *p*-chloro-di-methyl-aniline (Koch, *B.* 20, 2459; cf. Heidberg, *B.* 20, 149).

## CHLORO-NITRO-NAPHTHALENE

$C_{10}H_7Cl(NO_2)$  [14]. [85°]. From (α)-chloro-naphthalene and cold  $HNO_3$  (S.G. 1.4). Extremely slender, light yellow concentric needles.  $PCl_5$  gives (β)-di-chloro naphthalene. Tin and  $HCl$  reduce it to (α)-naphthylamine (Atterberg, B. 9, 927).

(α')-Chloro-di-nitro-naphthalene  
 $C_{10}H_6Cl(NO_2)_2$  [14:1]. [106°]. Formed, together with the foregoing by treating (α)-chloro-naphthalene with warm  $HNO_3$  (S.G. 1.4) (A.; Faust a. Saame, A. 160, 68). Long yellow pliable needles, v. sol. hot alcohol.  $PCl_5$  converts it into (β)-tri-chloro-naphthalene.

(β')-Chloro-di-nitro-naphthalene probably  
 $NO_2, NO_2$

[180°] (A.); [175°] (E.). Obtained

by the action of hot fuming  $HNO_3$  on (α)-chloro-naphthalene (Atterberg). Formed by the action of  $HNO_3$  upon chloro-nitro-(α)-naphthoic acid [255°] (Ekstrand, B. 18, 2881). Glistening yellow needles (from alcohol). Sl. sol. boiling alcohol.

(β'')-Di-chloro-nitro-naphthalene  
 $C_{10}H_5Cl_2(NO_2)$  [14:1]. [92°]. From (β')-di-chloro-naphthalene and  $HNO_3$  (S.G. 1.45) (Widmann, Bl. [2] 28, 509). With  $PCl_5$  it gives (β)-tri-chloro-naphthalene.

Di-chloro-nitro-naphthalene  $C_{10}H_5Cl_2(NO_2)$  [95°]. Formed, together with an isomeride [142°], by the action of cold conc.  $HNO_3$  on (β)-di-chloro-naphthalene (Alén, Bl. [2] 36, 433).

Di-chloro-nitro-naphthalene  $C_{10}H_5Cl_2(NO_2)$  [c. 114°]. From (ε)-di-chloro-naphthalene and cold fuming  $HNO_3$  (Alén, Bl. [2] 36, 435). Yellowish needles.

(γ)-Di-chloro-nitro-naphthalene  
 $C_{10}H_5Cl_2(NO_2)$  [119°]. Formed by adding fuming  $HNO_3$  to a solution of (γ)-di-chloro-naphthalene in  $HOAc$  (Clève, Bl. [2] 29, 499). Golden-yellow needles; m. sol. boiling alcohol.  $PCl_5$  forms (ε)-tri-chloro-naphthalene.

Di-chloro-nitro-naphthalene  $C_{10}H_5Cl_2(NO_2)$  [139°]. Formed, together with the isomeride [114°], by treating (ε)-di-chloro-naphthalene with cold fuming  $HNO_3$  (Alén, Bl. [2] 36, 435). Needles, turning brownish-violet in the air.

Di-chloro-nitro-naphthalene  $C_{10}H_5Cl_2(NO_2)$  [142°]. From (δ)-di-chloro-naphthalene and cold conc.  $HNO_3$  (Alén, Bl. [2] 36, 433). Needles, turning green in the air.

(γ)-Di-chloro-nitro-naphthalene  
 $C_{10}H_5Cl_2(NO_2)$  [142°]. From (γ)-di-chloro-naphthalene and cold  $HNO_3$  (S.G. 1.4) (Atterberg, B. 9, 928). Short sulphur-yellow brittle prisms (from  $HOAc$ ).  $PCl_5$  gives (β)-tri-chloro-naphthalene.

(β'')-Di-chloro-di-nitro-naphthalene  
 $C_{10}H_4Cl_2(NO_2)_2$  [158°]. Formed by adding  $HNO_3$  (S.G. 1.48) to a solution of (β')-di-chloro-naphthalene in  $HOAc$  (Widmann, Bl. [2] 28, 510). Long yellow needles; sl. sol. alcohol.

(γ)-Di-chloro-di-nitro-naphthalene  
 $C_{10}H_4Cl_2(NO_2)_2$  [246°]. From (γ)-di-chloro-naphthalene [142°] and  $HNO_3$  mixed with  $H_2SO_4$  (Atterberg, B. 9, 1730). Light yellow brittle prismatic needles; v. sl. sol. all solvents.  $PCl_5$  gives (ε)-tetra-chloro-naphthalene.

(δ)-Di-chloro-di-nitro-naphthalene  
 $C_{10}H_4Cl_2(NO_2)_2$  [246°]. Formed by adding fuming  $HNO_3$  to a solution of (δ)-di-chloro-naphthalene in  $HOAc$  (Alén, Bl. [2] 36, 434). Pale yellow prisms, turning green in air.

(ε)-Di-chloro-di-nitro-naphthalene  
 $C_{10}H_4Cl_2(NO_2)_2$  [253°]. Formed by acting on (ε)-di-chloro-naphthalene dissolved in glacial acetic acid with fuming  $HNO_3$  (Alén, Bl. [2] 36, 435; Claus a. Dehne, B. 15, 320). Pale yellow needles, turning red in air.  $PCl_5$  gives (ζ)-tri-chloro-naphthalene. Alcohol KOH forms  $C_{10}H_3(OEt)_3(NO_2)_2$ .

Di-chloro-tri-nitro-naphthalene  
 $C_{10}H_3Cl_3(NO_2)_3$  [178°]. From (α')-di-chloro-naphthalene,  $H_2SO_4$ , and  $HNO_3$  (S.G. 1.48) (Widmann, Bl. [2] 28, 505). Brittle yellow prisms (from  $HOAc$ ); sl. sol. alcohol, v. sol. chloroform.

(ε)-Di-chloro-tri-nitro-naphthalene  
 $C_{10}H_3Cl_3(NO_2)_3$  [200°]. Formed by boiling (ε)-di-chloro-naphthalene with fuming  $HNO_3$  (Alén, Bl. [2] 36, 435). Pale yellow needles.  $PCl_5$  gives (η)-tetra-chloro-naphthalene [160°].

Di-chloro-tri-nitro-naphthalene  
 $C_{10}H_3Cl_3(NO_2)_3$  [201°]. Formed by acting on (β)-di-chloro-naphthalene with fuming  $HNO_3$  at 100° (Alén, Bl. [2] 36, 434). Pale yellow needles, turning greenish in the air.

Tetra-chloro-nitro-naphthalene  
 $C_{10}H_2Cl_4(NO_2)$  [155°]. From (δ)-tetra-chloro-naphthalene and conc.  $HNO_3$  (Atterberg a. Widmann, B. 10, 1841). Large pale-yellow trimetric prisms (from alcohol-toluene).  $PCl_5$  gives (β')-penta-chloro-naphthalene.

## CHLORO-NITRO-(α)-NAPHTHOIC ACID

$C_{10}H_5Cl(NO_2)(CO_2H)$  probably [225°].

Formed by nitration of chloro-(α)-naphthoic acid [245°]. Prismatic needles.

Ethyl ether AEt: [121°]; tables (from alcohol) (Ekstrand, B. 18, 2881).

TRI-CHLORO-TETRA-NITRO-DI-(β)-NAPHTHYL-ETHANE  $C_{22}H_{10}(NO_2)_4Cl_3$  [258°]. From tri-chloro-di-(β)-naphthyl-ethane ( $C_{10}H_7$ ) $CH_2CCl_2$  and  $HNO_3$  (Grabowski, B. 11, 298). Crystalline powder, insol. alcohol, ether, and  $HOAc$ .

DI-CHLORO-TETRA-NITRO-DI-(α)-NAPHTHYL-ETHYLENE  $C_{22}H_{10}(NO_2)_4Cl_2$  [214°]. From di-chloro-di-(α)-naphthyl-ethylene ( $C_{10}H_7$ ) $C_2CCl_2$  and fuming  $HNO_3$  (Grabowski, B. 11, 299).

Di-chloro-tetra-nitro-di-(β)-naphthyl-ethylene  $C_{22}H_{10}(NO_2)_4Cl_2$  [298°]. Formed by nitrating di-chloro-di-(β)-naphthyl-ethylene (G.).

CHLORO-NITRO-α-OXY-BENZOIC ACID  
 $C_8H_5Cl(NO_2)(OH)CO_2H$  [5:2:2:1]. [163°]. Prepared by nitration of m-chloro-salicylic acid (Smith a. Peirce, B. 13, 34; Ann. 1, 176). Short needles.

Salts.—A'K: soluble yellow needles.—A'Ba: sparingly soluble orange needles.—A'Ag: insol. pp.

Ethyl ether AEt: [89°]; colourless flat needles.

Amide [199°]. Sl. sol. water, v. sol. alcohol.

Chloro-di-nitro-o-oxy-benzoic acid  $\text{C}_6\text{HCl}(\text{NO}_2)_2(\text{OH})\cdot\text{CO}_2\text{H}$ . [78°]. From chloro-salicylic acid and fuming  $\text{HNO}_3$  (Hasse, B. 10, 2191). Long yellow needles (from water).

(Py. 1:2)-DI-CHLORO-(B. 1:8or4)-DI-NITRO-(Py. 8) OXY-(B. 2)-METHYL-QUINOLINE

$\text{C}_{10}\text{H}_7\text{N}_2\text{Cl}_2\text{O}_2$ , *i.e.*  $\text{C}_6\text{H}(\text{CH}_3)(\text{NO}_2)_2$   $\begin{matrix} \text{COCl}:\text{COCl} \\ \diagup \quad \diagdown \\ \text{N}:\text{C}(\text{OH}) \end{matrix}$

• Di-chloro-di-nitro-tolucarbostyryl. [186°]. Formed by nitration of (Py. 1:2:3)-di-chloro-oxy-(B. 2)-methyl-quinoline in cold  $\text{H}_2\text{SO}_4$  solution by means of  $\text{NO}_2$ . Long yellow needles with greenish reflex (Rügheimer a. Hoffmann, B. 18, 2988).

$\beta$ -CHLORO-o-NITRO- $\alpha$ -OXY- $\beta$ -PHENYL-PROPIONIC ACID  $\text{C}_9\text{H}_6\text{ClNO}_3$ , *i.e.*  $[2:1]\text{C}_6\text{H}_4(\text{NO}_2)\cdot\text{CHCl}\cdot\text{CH}(\text{OH})\cdot\text{CO}_2\text{H}$ . [126°]. From o-nitro- $\alpha$ -oxy-cinnamic acid and fuming  $\text{HCl}$  (Lipp, B. 19, 2049). Needles (from ether-ligroin). Alcoholic  $\text{KOH}$  re-converts it into o-nitro- $\alpha$ -oxy-cinnamic acid.

$\beta$ -Chloro-p-nitro- $\alpha$ -oxy- $\beta$ -phenyl-propionic acid  $[4:1]\text{C}_6\text{H}_4(\text{NO}_2)\cdot\text{CHCl}\cdot\text{CH}(\text{OH})\cdot\text{CO}_2\text{H}$ . [168°]. From p-nitro- $\alpha$ -oxy-cinnamic acid and fuming  $\text{HCl}$  (L.). Small glittering needles; sl. sol. cold water. The Ba salt is split up by boiling water into  $\text{CO}_2$ ,  $\text{BaCl}_2$ , and p-nitro-phenyl-acetic aldehyde. Alcoholic  $\text{KOH}$  gives p-nitro- $\alpha$ -oxy-cinnamic acid.

$\alpha$ -Chloro-o-nitro- $\beta$ -oxy- $\beta$ -phenyl-propionic acid  $[2:1]\text{C}_6\text{H}_4(\text{NO}_2)\cdot\text{CH}(\text{OH})\cdot\text{CHCl}\cdot\text{CO}_2\text{H}$ . [120°]. Formed by passing chlorine into a solution of o-nitro-cinnamic acid in dilute aqueous  $\text{NaOH}$  (Bayer, B. 13, 2261). Crystalline mass (from benzene-ligroin). Sol. ether. Converted by  $\text{NaOH}$  and  $\text{FeSO}_4$  into indole. Alcoholic  $\text{KOH}$  gives o-nitro- $\beta$ -oxy-cinnamic acid.

$\alpha$ -Chloro-p-nitro- $\beta$ -oxy-phenyl-propionic acid  $[4:1]\text{C}_6\text{H}_4(\text{NO}_2)\cdot\text{CH}(\text{OH})\cdot\text{CHCl}\cdot\text{CO}_2\text{H}$ . [165°]. Prepared in the same way from p-nitro-cinnamic acid (Beilstein a. Kuhlberg, A. 163, 142). Tri-metric plates (from water).  $\text{HCl}$  (S.G. 1.1) at 160° gives chloro-nitro-cinnamic acid.  $\text{Na}_2\text{CO}_3\text{Aq}$  gives, on warming, p-nitro- $\beta$ -oxy-cinnamic acid.

CHLORO-o-NITRO-PHENOL  $\text{C}_6\text{H}_4\text{ClNO}_2$ , *i.e.*  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OH})$  [3:6:1]. Mol. w. 173½. [39°] (L.). [40° and 32½°] (U.).

Formation.—1. By boiling (3,6,1)-chloro-di-nitro-benzene with aqueous  $\text{NaOH}$  (Laubenheimer, B. 9, 768).—2. By nitrating m-chloro-phenol (Uhlemann, B. 11, 1181).

Properties.—Lemon-yellow needles or prisms (from water).

Salts.— $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{ONa})$ : scarlet prisms, m. sol. cold water.— $\text{BaA}'$ , aq: slender scarlet needles.— $\text{AgA}'$ .

Methyl ether  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OMe})$ . [70-5°]. Needles.

Chloro-o-nitro-phenol  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OH})$  [6:2:1]. [70°]. • Formed, together with the isomeride [111°], by treating o-chloro-phenol with nitric acid (S.G. 1.58) diluted with an equal weight of water (Faust a. Müller, A. 178, 809). Flat yellow needles (from chloroform). Volatile with steam.  $\text{HNO}_3$  gives chloro-di-nitro-phenol [111°].

Salts.— $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OK})$ : long dark-red needles, v. sol. water.— $\text{CaA}'$ , aq: reddish-brown prisms, m. sol. water.— $\text{BaA}'$ , aq: short copper-  
Vol. II.

brown plates, sl. sol. water.— $\text{AgA}'$ : carmine-red scales, sl. sol. water.

Chloro-o-nitro-phenol  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OH})$  [4:2:1]. [87°].

Formation.—1. The sole product of the action of dilute  $\text{HNO}_3$  on p-chloro-phenol (Faust, B. 6, 132; A. 173, 317; Suppl. 7, 190; Z. [2] 5, 450). 2. By chlorination of o-nitro-phenol (Armstrong a. Pravost, B. 7, 922).—8. One of the products of the action of alcoholic  $\text{KOH}$  on (4,2,1)-chloro-di-nitro-benzene (Laubenheimer, B. 7, 1601).

Properties.—Light yellow monoclinic prisms (from  $\text{CHCl}_3$ ). V. sl. sol. water, m. sol. alcohol. Volatile with steam. Br and water at 100° give chloro-bromo-nitro-phenol [125°] (Ling, C. J. 61, 786). But Br in  $\text{HOAc}$  gives an isomeric chloro-bromo-nitro-phenol [120°].

Salts.— $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{ONH}_2)$ : orange-red needles.— $\text{NaA}'$ , aq: red prisms.— $\text{BaA}'$ , 4aq: short red prisms.— $\text{AgA}'$ .

Ethyl ether  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OEt})$ . [62°]. From  $\text{AgA}'$  and  $\text{EtI}$ . Formed also by nitrating the ethyl ether of p-chloro-phenol (Hallock, Am. 2, 258; B. 14, 37).

Chloro-p-nitro-phenol  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OH})$  [2:4:1]. [111°].

Formation.—1. By chlorinating p-nitro-phenol (Armstrong, C. J. 25, 12; Faust a. Müller, A. 173, 309; Kollrepp, A. 234, 4).—2. Together with the isomeride [70°], by treating o-chloro-phenol with dilute  $\text{HNO}_3$  (F. a. M.).—3. From chloro-di-nitro-phenol [111°] by reduction to chloro-nitro-amido-phenol followed by displacement of  $\text{NH}_2$  by  $\text{Cl}$  through the diazo-reaction (Faust, Z. 1871, 339).

Properties.—White silky needles, m. sol. boiling water, v. sol. alcohol, ether, and chloroform. Very slightly volatile with steam.  $\text{HNO}_3$  converts it into chloro-di-nitro-phenol [111°].

Salts.— $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OK})$ : brown needles, v. sol. water.— $\text{CaA}'$ , aq: tufts of canary-yellow needles, v. sol. water.— $\text{BaA}'$ , 7aq: long dark-yellow needles.— $\text{AgA}'$ : copper-brown flattened needles, sl. sol. water.

Methyl ether  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OMe})$ . From the methyl ether of nitro-o-amido-phenol by displacement of  $\text{NH}_2$  by  $\text{Cl}$ . Needles.

Ethyl ether  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OEt})$ . Chloro-nitro-phenol. [78°]. Formed by chlorinating the ethyl ether of p-nitro-phenol by  $\text{HCl}$  and  $\text{KClO}_4$  (Hallock, B. 14, 37; Am. 3, 21).

Chloro-nitro-phenol. Methyl ether  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)(\text{OMe})$  [2:2:1]. Chloro-nitro-anisol. [34°]. Prepared by nitration of the methyl ether of o-chloro-phenol (Fischli, B. 11, 1461). Colourless spikes.

Chloro-di-nitro-phenol  $\text{C}_6\text{H}_2\text{Cl}(\text{NO}_2)_2(\text{OH})$  [4:2:6:1]. [81°].

Formation.—1. From p-chloro-phenol and  $\text{HNO}_3$  (S.G. 1.4) (Dubois, Z. 1867, 205).—2. By nitration of p-chloro-phenol sulphonic acid (Peterson a. Praderi, A. 167, 156).—3. By nitrating chloro-nitro-phenol [87°] (Faust a. Saame).—4. From di-chloro-di-nitro-benzene [104°] and boiling aqueous  $\text{NaOH}$  (Engelhardt a. Latschinnoff, Z. 1870, 234; Körner, G. 4, 395).—5. By chlorinating (1,3)-di-nitro-phenol (Armstrong, B. 6, 649).—6. In small quantity, together with the isomeride [111°], by the action of  $\text{ICl}$  on tri-nitro-phenol (picric acid) (Peterson, B. 6, 869; Armstrong, loc. cit.).—7. By boiling chloro-  
H

## CHLORO-NITRO-PHENOL

di-nitro-aniline [145°] with aqueous KOH (Körner).—8. By dissolving chloro-o-oxy-benzoic acid in fuming HNO<sub>3</sub> (Smith a. Peirce, *A. Ph. S.* 17, 707; *Am. I.* 176; *B.* 13, 35).

**Properties.**—Yellow monoclinic prisms (from chloroform). Sl. sol. hot water, v. sol. alcohol. Combines with aniline, forming C<sub>6</sub>H<sub>4</sub>ClN<sub>2</sub>O<sub>2</sub>NH<sub>2</sub>C<sub>6</sub>H<sub>5</sub> [187°] (S. a. P.); decomposed by boiling water.

**Salts.**—C<sub>6</sub>H<sub>4</sub>Cl(NO<sub>2</sub>)(OK): long red needles with green lustre; v. sol. hot, v. sl. sol. cold water.—NH<sub>4</sub>A': deep orange needles.—NaA': 3aq: scarlet moss-like forms.—BaA': aq: pale, saffron-yellow needles, v. sl. sol. hot water.—CuA': 2aq: saffron-yellow needles.—PbA': aq: yellow needles. AgA': red needles.

**Methyl ether** C<sub>6</sub>H<sub>4</sub>Cl(NO<sub>2</sub>)(OMe): [65°].

**Ethyl ether** C<sub>6</sub>H<sub>4</sub>Cl(NO<sub>2</sub>)(OEt): [55°].

**Chloro-di-nitro-phenol** C<sub>6</sub>H<sub>3</sub>Cl(NO<sub>2</sub>)<sub>2</sub>(OH). [80°]. Formed, together with the preceding, with which it is perhaps identical, by nitrating chloro-o-oxy-benzoic acid (Smith a. Peirce, *A. Ph. S.* 17, 707). Solidifies at 25°, whereas the preceding solidifies at 69°.—KA': 1½aq: orange needles, much more soluble in water than the K salt of the preceding.—AgA': bronzed needles.

**Chloro-di-nitro-phenol** C<sub>6</sub>H<sub>3</sub>Cl(NO<sub>2</sub>)<sub>2</sub>(OH) [34:6:1]. [111°] (F. a. S.); [96°] (Zehenter, *M.* 6, 527). S. 0.52 at 10°.

**Formation.**—1. From o-chloro-phenol and conc. HNO<sub>3</sub> (Griess, *A.* 109, 286; Armstrong, *C. J.* 25, 96; Faust a. Müller, *A.* 173, 312).—2. From o- or p-nitro-phenol by successive chlorination and nitration (Faust a. Saame, *A. Suppl.* 7, 195; Seifart, *A. Suppl.* 7, 198).—3. The chief product of the action of ICl on picric acid (Petersen, *B.* 6, 368).—4. By chlorinating di-nitro-phenol [114°] (Armstrong, *C. J.* 25, 12; Faust, *Z.* 1871, 339).—5. By nitrating (3,4,1)-chloro-nitro-phenol (Armstrong; F. a. M.).—6. By nitrating (2,6,1)-chloro-nitro-phenol (F. a. M.).—7. From di-nitro-amido-phenol (picramic acid), by displacing NH<sub>2</sub> by Cl through the diazo-reaction (F.).—8. By the action of HNO<sub>3</sub> on di-chloro-phenol p-sulphonic acid (Armstrong, *C. J.* 24, 1112).—9. From di-chloro-p-nitro-phenol and HNO<sub>3</sub> (A.).—10. By nitrating o-chloro-phenol sulphonic acid (Armstrong a. Prevost, *B.* 7, 405).

**Properties.**—Yellowish laminae (from alcohol) or irregular six-sided tables (from CHCl<sub>3</sub>). Sl. sol. hot water, m. sol. alcohol and ether. Tastes bitter.

**Salts.**—C<sub>6</sub>H<sub>3</sub>Cl(NO<sub>2</sub>)<sub>2</sub>(OK)aq: short slender yellow needles.—NaA': 1½aq: short yellow needles.—NH<sub>4</sub>A': 1½aq.—NH<sub>4</sub>A' (G.).—NH<sub>4</sub>A' aq (F. a. S.).—BaA': 9aq (F. a. S.).—BaA', 10aq (F. a. M.).—CuA', 7aq: flat golden needles.—MgA', 7aq.—MgA', 10aq.—CuA', 8aq: greenish-yellow hair-like needles.—AgA' aq.

**Chloro-di-nitro-phenol** C<sub>6</sub>H<sub>3</sub>Cl(NO<sub>2</sub>)<sub>2</sub>(OH). [70°]. Formed in small quantity by nitrating di-chloro-phenol and aqueous NaOH (Engelhardt a. Latschinoff, *Z.* 1870, 284; Körner, *G.* 4, 395). Long needles.—BaA', 8aq: yellow needles.

**Di-chloro-nitro-phenol** C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(NO<sub>2</sub>)(OH) [34:6:1]. [122°].

**Formation.**—1. By nitrating di-chloro-phenol [48°] (Fischer, *A. Suppl.* 7, 186; Chandelon, *B.* 16, 1753) or its sulphonic acid (Armstrong, *C. J.* 24, 1119; 25, 98).—2. By passing chlorine into an aqueous solution of o-nitro-phenol p-sulphonic

acid (Schmitt a. Glutz, *B.* 2, 52).—3. By chlorinating chloro-nitro-phenol [37°] (Faust a. Saame, *A. Suppl.* 7, 195).—4. From o-chloro-phenol by successive nitration and chlorination (A.).—5. By chlorinating chloro-nitro-phenol sulphonic acid (A.).—6. From di-chloro-o-oxy-benzoic acid by dissolving in HOAc and treating with HNO<sub>3</sub> (Smith a. Kner, *Am.* 8, 95).

**Properties.**—Yellow laminae (from alcohol). Sl. sol. water, forming a deep yellow solution. V. sol. alcohol and ether. Volatile with steam. Explodes when heated suddenly. HNO<sub>3</sub> forms chloro-di-nitro-phenol [81°]. Bromine and water at 100° form chloro-tri-bromo-quinone (Ling, *C. J.* 51, 781).

**Salts.**—C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(NO<sub>2</sub>)(ONH<sub>2</sub>): orange needles; may be sublimed.—NaA': nodular groups of orange-red needles.—KA': needles of the colour of CrO<sub>3</sub>.—KA' aq (Faust, *A.* 173, 317). BaA', 2aq: orange needles, v. sl. sol. water.—MgA', 2aq.—PbA' (OH).—ZnA', 2aq.

**Ethyl ether** C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(NO<sub>2</sub>)(OEt). [29°]. Pearly prisms.

**Acetyl derivative** C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(NO<sub>2</sub>)(OAc). [77°]. From NaA' and AcCl.

**Di-chloro-nitro-phenol** C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(NO<sub>2</sub>)(OH) [6:2:4:1]. [125°].

**Formation.**—1. By chlorinating p-nitro-phenol (Seifart, *A. Suppl.* 7, 198; Kolrepp, *A.* 234, 8).—2. By nitrating di-chloro-phenol sulphonic acid (Armstrong, *C. J.* 24, 1112; Faust, *Z.* 1871, 338).

**Properties.**—Slightly yellowish prisms or tables (from ether), or colourless needles (from chloroform). V. sl. sol. hot water; not volatile with steam. Converted by heat into di-chloro-quinone. NO<sub>2</sub> and N (Armstrong a. Brown, *B.* 7, 928). HNO<sub>3</sub> (S. G. 1:45) forms chloro-di-nitro-phenol [111°]. Bromine and water at 100° form di-chloro-di-bromo-quinone (Ling, *C. J.* 51, 786).

**Salts.**—C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(NO<sub>2</sub>)(ONH<sub>2</sub>) aq: shining yellow needles, becoming anhydrous and colourless over H<sub>2</sub>SO<sub>4</sub>.—NaA' 5aq: yellow needles.—KA' aq: orange needles.—BaA', 3½aq: red needles (Ling, *C. J.* 51, 786).—BaA', 4aq (S.): brown-red laminae or red needles.—BaA', 8aq: yellow needles (F. a. M.; *A.* 173, 311).—CaA', 9aq: golden needles or laminae, v. sol. water.—CdA', 8½aq.—PbA', 4½aq.—CuA', 5aq.—MgA', 10aq: rosettes of yellow needles.—AgA': colourless needles.

**Ethyl ether** C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(NO<sub>2</sub>)(OEt) [85°].

**Di-chloro-nitro-phenol** C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(NO<sub>2</sub>)(OH). Formed in small quantity by nitrating di-chloro-phenol with ClSO<sub>3</sub>H (Armstrong, *Z.* 1871, 679). Short yellow needles (from water).

**Tri-chloro-nitro-phenol** C<sub>6</sub>H<sub>2</sub>Cl<sub>3</sub>(NO<sub>2</sub>)(OH) [6:4:2:3:1]. [69°]. Obtained by saponifying its nitro-benzoyl derivatives, which are obtained by nitrating benzoyl-tri-chloro-phenol (Dacomo, *B.* 18, 1164). Glistening colourless needles. V. sol. alcohol, ether, and benzene, sl. sol. water. Fe<sub>2</sub>Cl<sub>6</sub> gives a violet-blue colouration.

**Salts.**—A'NH<sub>4</sub>: small yellow needles.—A'K aq.—A'Ag: small yellow needles.—A'Ba aq: yellow plates.

**o-Nitro-benzoyl derivatives** C<sub>6</sub>H<sub>2</sub>Cl<sub>3</sub>(NO<sub>2</sub>)<sub>2</sub>OCO.C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>). [108° cor.]: oil colourless glistening scales; sol. alcohol and ether

*m*-Nitro-benzoyl derivative  
 $C_6H_4(NO_2)COO.C_6H_4(NO_2)$  [148° cor.]; large colourless tables; sol. alcohol and ether, insol. water.

*Ethyl ether* (?) [54°]. From tri-chloro-phenetol and cold  $H_2SO_4$  and  $HNO_3$  (Faust, A. 149, 152).

Tri-chloro-nitro-phenol  $C_6H_2Cl_3(NO_2)(OH)$  [2:3:5:4:1]. [148°]. From tri-chloro-phenol [54°] and  $HNO_3$ . White needles. Reduces to tri-chloro-*p*-amido-phenol (Lampert, J. pr. [2] 33, 382).

*Ethyl ether*  $C_6H_2Cl_3(NO_2)(OEt)$ . [69°]. Tri-chloro-di-nitro-phenol. *Ethyl ether*  $C_6H_2Cl_3(NO_2)_2(OEt)$ . [100°]. From tri-chloro-phenetol and warm  $HNO_3$ , mixed with  $H_2SO_4$  (Faust, A. 149, 152).

CHLORO-NITRO-PHENOL SULPHONIC ACID  $C_6H_3Cl(NO_2)(OH)(SO_3H)$  [2:3:1:4]. From di-chloro-phenol sulphonic acid and cold  $HNO_3$  (Armstrong, C. J. 24, 1117). Formed also by nitrating *o*-chloro-phenol sulphonic acid (Armstrong a. Prevost, B. 7, 404). An isomeric acid is formed by chlorinating nitro-phenol sulphonic acid (Armstrong a. Brown, C. J. 25, 872).  $HNO_3$  converts it into chloro-di-nitro-phenol [111°]. Chlorine forms di-chloro-nitro-phenol [121°].

Salts.— $C_6H_3Cl(NO_2)_2K$ : orange-red six-sided plates, v. e. sol. hot water.— $C_6H_3Cl(NO_2)_2K$  aq: yellow needles.

#### DI-CHLORO-DI-NITRO-DIPHENYL

$C_6H_4(NO_2)Cl.C_6H_4(NO_2)Cl$ . [140°]. Prepared by the nitration of di-chloro-diphenyl. [4:1]  $C_6H_4Cl.C_6H_4Cl$  [1:4] (Schmidt a. Schultz, B. 12, 494). Small needles or long prisms. Sl. sol. cold, v. sol. hot, alcohol, and  $C_6H_6$ .

#### CHLORO-NITRO-DI-PHENYL-AMINE

$C_6H_4ClNO_2$ , i.e.  $C_6H_4.NH.C_6H_4Cl(NO_2)$ . [109°]. Slowly formed, together with benzene-azo-aniline (amido-azo-benzene) by mixing (1,3,4)-chloro-di-nitro-benzene [89°] (1 mol.) with aniline (3 mols.) (Laubenheimer, B. 9, 771). Long red needles (from alcohol). Does not combine with acids.

Nitrosamine  $C_6H_4.N(NO).C_6H_4Cl(NO_2)$ . [111°]. Yellow, six-sided laminae, m. sol. cold alcohol.

#### CHLORO-DI-NITRO-DI-PHENYL-AMINE-*o*-CARBOXYLIC ACID

$C_6H_4(NO_2)Cl.NH.C_6H_4.CO_2H$  [256°]. Formed by mixing alcoholic solutions of di-chloro-di-nitro-benzene  $C_6H_3Cl_2(NO_2)_2$  [1:4:2:3] and anthranilic acid  $C_6H_4(NH_2)CO_2H$  [1:2] and adding  $NH_3$  (Jourdan, B. 18, 1454). Glistening red prisms. Sol. hot alcohol and acetic acid, insol. water.

Chloro-di-nitro-di-phenyl-amine-*o*-carboxylic acid  $C_6H_4(NO_2)_2.NH.C_6H_4Cl.CO_2H$  [282° uncor.]. Obtained by mixing alcoholic solutions of chloro-di-nitro-benzene  $C_6H_3Cl(NO_2)_2$  [1:2:4] and chloro-amido-benzoic acid  $C_6H_3Cl(NO_2)CO_2H$  [1:4:5], and adding  $NH_3$  (Jourdan, B. 18, 1450). Fine orange needles. V. sl. sol. cold alcohol and acetic acid, insol. water, benzene, and ligroin. A°:Ca: sl. sol. water.

#### TRI-CHLORO-DI-NITRO-DI-PHENYL-

BUTANE  $C_6H_2Cl_3(NO_2)_2$ . From tri-chloro-diphenyl-butane and fuming  $HNO_3$  (Hepp, B. 7, 1420). Small yellowish tables (from alcohol). Sl. sol.  $CS_2$ , v. sol. ether.

#### CHLORO-NITRO-PHENYLENE-DIAMINE

$C_6H_3Cl(NO_2)(NH_2)$  [1:4:3:5]. [192°-194°]. From  $C_6H_3Cl_2(NO_2)$  [1:3:5:2] and alcoholic  $NH_3$  at 200° for several days (Beilstein a. Kurbatoff, A. 192, 238). Red needles. V. sol. alcohol, sol. dilute (50 per cent.) acetic acid or benzene, sl. sol. light petroleum.

#### DI-CHLORO-NITRO-PHENYL-ETHANE

DI-CHLORO-NITRO-ETHYL-BENZENE.

#### Penta-chloro-di-nitro-di-phenyl-ethane

$C_6H_2Cl_5N_2O_2$ , i.e.  $CCl_2.CH(C_6H_2Cl_3NO_2)_2$ . [148°]. From  $CCl_2.CH(C_6H_2Cl_3)$  and fuming  $HNO_3$  (Zeidler, B. 7, 1181). Needles (from alcohol).

#### CHLORO-NITRO-PHENYL MERCAPTAN

$C_6H_4ClNO_2$ , i.e.  $C_6H_4Cl(NO_2)(SH)$  [3:8:1]. [171°]. From (3,8,1)-chloro-di-nitro-benzene and alcoholic KSH (Beilstein a. Kurbatoff, A. 197, 82). Yellow needles, v. sol. chloroform, v. sl. sol. alcohol.

#### Chloro-nitro-phenyl mercaptan

$C_6H_4Cl(NO_2)(SH)$  [4:3:1]. [213°]. From (1,4,8)-di-chloro-nitro-benzene and alcoholic KSH (Beilstein a. Kurbatoff, A. 197, 79). Yellow tables (from HOAc). Sl. sol. alcohol. Alcoholic ammonium sulphide converts it into  $C_6H_4Cl_2N_2S$  [147°], which crystallises in yellow needles, and is converted by  $HNO_3$  into  $C_6H_4ClN_2S$  [104°].

#### CHLORO-NITRO-PHENYL-*m*-PHENYLENE-

DIAMINE  $NH_2.C_6H_4.NH.C_6H_4Cl(NO_2)$ . [151°]. Red needles. Sl. sol. cold alcohol. Prepared by warming an alcoholic solution of *m*-phenylene-diamine and (1,3,4)-chloro-di-nitro-benzene. Forms with acids unstable yellow salts (Laubenheimer, B. 11, 1158).

#### (Py. 4:1:2)-CHLORO-NITRO-PHENYL-ISO-

QUINOLINE  $C_{10}H_6ClO.N$ , i.e.  $C_6H_4Cl(NO_2).C_6H_4$

[156°]. Formed by heating nitro-oxy-phenyl-isquinoline (nitro-iso-benzal-phthalimidine) with  $POCl_3$  (Gabriel, B. 19, 834). Small yellow needles or prisms. V. sol. hot acetic acid, benzene, chloroform, ether, and  $CS_2$ ; sl. sol. alcohol, v. sl. sol. ligroin. By HI and P it is reduced to amido-phenyl-isquinoline. Heated with alcoholic sodium ethylate it yields the ethyl-ether of nitro-oxy-phenyl-isquinoline.

#### DI-CHLORO-DI-NITRO-DI-PHENYL-SUL-

PHIDE  $(C_6H_4ClNO_2)_2S$ . [150°]. Yellow needles. Almost insol. alcohol, sl. sol. acetic acid. Prepared by the action of alcoholic  $K_2S$  on (1, 4, 6)-di-chloro-nitro-benzene (Beilstein a. Kurbatow, B. 11, 2056; A. 197, 79).

#### CHLORO-NITRO-PHENYL-*p*-TOLYL-AMINE

$C_6H_4Me.NH.C_6H_4Cl(NO_2)$ . [124°]. Small red needles. Sl. sol. cold alcohol. Prepared by the action of a cold alcoholic solution of *p*-toluidine on (1, 3, 4)-chloro-di-nitro-benzene (Laubenheimer, B. 11, 1157).

#### DI-CHLORO-DI-NITRO-DI-PHENYL-UREA

$C_6H_4ClNO_2$ , i.e.  $CO(NH.C_6H_4ClNO_2)_2$ . [210°]. From di-chloro-di-phenyl-guanidine and  $HNO_3$  (Losanitch, Bl. [2] 83, 170). Yellow tables, in sol. water, sl. sol. alcohol.

#### CHLORO-NITRO-PHTHALIC ACID

$C_6H_3ClNO_2$ , i.e.  $C_6H_3Cl(NO_2)(CO_2H)$ . From (γ) di-chloro-naphthalene and  $HNO_3$  (Atterberg, B. 10, 547).—K.A°: crystals; explodes above 800° Di-chloro-nitro-phthalic acid. From (Q) tri-chloro-naphthalene and  $HNO_3$  (S.G. 1:2) at 150 (Widmann, B. 12, 990).

Tri-chloro-nitro-phthalic acid  $C_6H_2Cl_3NO_2$ . From (α)-tri-chloro-naphthalene and  $HNO_3$  (Atterberg & Widmann, B. 10, 1844).

#### DI-CHLORO-DI-NITRO-PROPANE

$C_3H_4Cl_2(NO_2)_2$  (?). From di-chloro-propylene (from tri-chloro-butyric aldehyde) and fuming  $HNO_3$  (Pinner, A. 179, 49). Oil; converted by tin and  $HCl$  into  $C_3H_5Cl_2$  (19°),  $C_3H_4Cl_2(NH_2)$ , and tri-chloro-nitro-propane.

Tri-chloro-nitro-propane  $C_3H_2Cl_3(NO_2)_2$  (c. 193°). Formed as above.

#### DI-CHLORO-NITRO-PROPYLENE

$C_3H_3Cl_2(NO_2)$  (c. 159°). Formed by the action of aqueous  $NaOH$  upon di-chloro-di-nitro-propane and upon tri-chloro-nitro-propane (Pinner, A. 179, 57).

CHLORO-NITRO-QUINOLINE  $C_8H_5Cl(NO_2)N$  [190°–128°]. Formed, together with the isomeride [186°], by nitration of (B. 1 or 3)-chloro-quinoline (La Coste & Bodewig, B. 17, 927). V. sol. hot alcohol, al. sol. water.

Chloro-nitro-quinoline  $C_8H_4Cl(NO_2)N$  [186°]. Formed, together with the preceding, by nitration of (B. 1 or 3)-chloro-quinoline (La Coste & Bodewig, B. 17, 927). Long colourless needles. Sl. sol. alcohol.

#### CHLORO-NITRO-QUINONE Anilide

$C_6H_3Cl(NO_2)(NHPh)O_2$  [6 or 2:3:2 or 6:4:1]. [208°]. Small red trimetric tables. Formed by the action of aniline in alcoholic solution upon di-chloro-nitro-quinone  $C_6H_2Cl_2(NO_2)_2$  [6:2:3:4:1] (Guaracchi & Daccamo, B. 18, 1172).

Di-chloro-nitro-quinone  $C_6H_2Cl_2(NO_2)_2$  [6:2:3:4:1]. [220°]. Formed by the action of a mixture of  $HNO_3$  and  $H_2SO_4$  upon the propionyl derivative of tri-chloro-phenol (Guaracchi & Daccamo, B. 18, 1171). Small yellow needles. Sol. cold alcohol, al. sol. ether and  $CS_2$ , v. sl. sol. hot water.

#### CHLORO-ISO-NITROSO-ACETIC ETHER

$N(OH):CClOOEt$  (?). Chloro-oximido-acetic ether. [80°]. From chloro-aceto-acetic ether (v. Allihn, B. 11, 567) and fuming  $HNO_3$  (Pröpper, A. 222, 50). Glittering columns (from ether). V. e. sol. alcohol and ether. Boiling water splits it up into hydroxylamine, oxalic acid, and alcohol.

#### CHLORO-ISO-NITROSO-ACETONE

$CH_3CO.CCl(OH)$ . Mon-oxim of α-chloro-pyruvic aldehyde. [110°]. Formed in small quantity by treating chloro-acetone with fuming  $HNO_3$  (Gluts, Z. 1870, 529; Barbaglia, B. 6, 321). Formed also by heating the product of the action of nitrous acid gas upon acetone ( $(CH_3)_2C(ONO)_2.C(OH).CO.CH_3$  (?), with dilute  $HCl$ ; acetone and  $HNO_3$  are formed at the same time (Sandmeyer, B. 20, 640). Prisms or tables; v. sol. water, alcohol, and ether.

Oxim  $CH_3C(OH)CCl(OH)$ . Di-oxim of α-chloro-pyruvic aldehyde. Chloro-methyl-gly-oxim. [171°]. Small white needles.

α-CHLORO-α-NITRO-STYRENE  $C_8H_6ClNO_2$ , i.e.  $C_8H_5(NO_2).CCl.CH_2$ . Nitro-phenyl-chloro-ethylene. From α-nitro-acetophenone and  $PCl_5$  (Gevakoh, A. 221, 329). Oil.

α-Chloro-p-nitro-styrene  $C_8H_5(NO_2).CCl.CH_2$  [64°]. From p-nitro-acetophenone and  $PCl_5$  (Drewson, A. 212, 162). Concentric groups of slender needles (from benzoline).

α-Chloro-α-nitro-styrene  $Ph.CCl:CH.NO_2$  [49°]. From  $PhOCHClCHCl.NO_2$  and aqueous

$NaOH$  (Priebs, A. 225, 345). Golden plates (from light petroleum). Insol. water, soluble, when finely divided, in alkalis.

α-Chloro-α-nitro-styrene  $C_8H_5(NO_2).CH:CHCl$  [59°]. Formed as a by-product in the preparation of chloro-α-nitro-oxy-phenyl-propionic acid by the action of hypochlorous acid on α-nitro-cinnamic acid (Lipp, B. 17, 1070). Glistening needles or prisms. V. sol. ether and hot alcohol, al. sol. hot water, insol. cold water.

#### TRI-CHLORO-NITRO-THIOPHENE

$C_4S_2Cl_3(NO_2)$ . [86°]. Formed by nitration of tri-chloro-thiophene. Reddish-yellow felted needles. V. sol. benzene and ether, less in alcohol (Rosenberg, B. 12, 652).

#### CHLORO-NITRO-TOLUENE

$C_7H_4(CH_3)Cl(NO_2)$  [1:4:3]. [9°]. \* (260° i. v.). S.G.  $\frac{4}{3}$  1.297.

Formation.—1. Together with the (1:2:4)-isomeride by nitration of p-chloro-toluene (10 pts.) with a cold mixture of conc.  $HNO_3$  (12 pts.) and conc.  $H_2SO_4$  (17 pts.) (Engelbrecht, B. 7, 797; Goldschmidt & Höning).—2. From m-nitro-p-toluidine  $C_7H_4(CH_3)(NO_2)(NH_2)$  [1:3:4] by the action of  $Cu_2Cl_2$  upon the diazo-compound (Gattermann & Kaiser, B. 18, 2509).

Reaction.—On reduction it gives p-chloro-m-toluidine [28°] (Goldschmidt & Höning, B. 19, 2438).

(α)-Chloro-nitro-toluene  $C_7H_4(CH_3)Cl(NO_2)$  [1:2:x]. [250°]. Oil. Formed by nitration of o-chloro-toluene. On reduction it gives a chloro-toluidine [83°] (Goldschmidt & Höning, B. 19, 2443; cf. Wroblewsky, A. 168, 200).

Chloro-nitro-toluene  $C_7H_4(CH_3)Cl(NO_2)$  [1:4:2]. [38°]. (240° at 718 mm.).

Formation.—1. Together with the (1:3:4) isomeride, by nitration of p-chloro-toluene (10 pts.) with a cold mixture of conc.  $HNO_3$  (12 pts.) and conc.  $H_2SO_4$  (17 pts.) (Engelbrecht, B. 7, 797; Goldschmidt & Höning, B. 19, 2438).—2. From o-nitro-p-toluidine by the action of  $Cu_2Cl_2$  upon the diazo-compound (Beilstein & Kuhlberg, A. 158, 336).

Properties.—Needles; al. sol. cold alcohol, volatile with steam. On reduction it gives p-chloro-o-toluidine [22°] (Goldschmidt & Höning, B. 19, 2438).

Chloro-nitro-toluene  $C_7H_4MeCl(NO_2)$  [1:2:5] [44°]. [248°] at 711 mm. Obtained by the action of  $Cu_2Cl_2$  upon diazotised nitro-o-toluidine  $C_7H_4Me(NH_2)(NO_2)$  [1:2:5]. Needles (from ether) (Goldschmidt & Höning, B. 20, 199).

Chloro-nitro-toluene  $C_7H_4(CH_3)Cl(NO_2)$  [1:3:5]. [55°]. Formed from m-nitro-m-toluidine  $C_7H_4Me(NO_2)NH_2$  [1:3:5] by the action of cuprous chloride upon the diazo-compound. Yellow needles (from alcohol). Volatile with steam (Höning, B. 20, 2419).

Chloro-nitro-toluene  $C_7H_4(CH_3)Cl(NO_2)$  [1:2:4]. [65°]. Formed by the action of  $PCl_5$  on p-nitro-toluene (Lellmann, B. 27, 594; cf. Wachendorf, A. 185, 278). Colourless crystals. V. sol. alcohol. Volatile with steam. On reduction it gives chloro-p-toluidine [28°] (238°).

Chloro-di-nitro-toluene  $C_7H_3(CH_3)Cl_2(NO_2)_2$  [1:4:3:5]. [48°]. Formed by nitration of chloro-nitro-toluene  $C_7H_4(CH_3)Cl(NO_2)$  [1:4:5]. Long white needles (Höning, B. 20, 2420).

Chloro-di-nitro-toluene  $C_7H_3(CH_3)(NO_2)_2C$  [1:2:7:8:4]. [76°]. Small yellow needles (from

ether). Formed by nitration of *p*-chloro-toluene with fuming  $\text{HNO}_3$  (Goldschmidt & Hönig, *B.* 19, 2439).

**Chloro-di-nitro-toluene**  $\text{C}_6\text{H}_4(\text{CH}_3)\text{Cl}(\text{NO}_2)_2$  [1:4:2:6]. [10F°]. Formed by nitration of *p*-chloro-*o*-nitro-toluene  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NO}_2)\text{Cl}$  [1:2:4]. Long white needles (Hönig, *B.* 20, 2420).

**Di-chloro-nitro-toluene**  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}_2(\text{NO}_2)$ .  $\mu$  14°. (274°). S.G. 1.455. From di-chloro-toluene and fuming  $\text{HNO}_3$  (Wroblewsky, *A.* 168, 212). Oil.

( $\beta$ )-Di-chloro-nitro-toluene  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}_2(\text{NO}_2)$  [1:2:4:7]. [53°]. Formed by the action of conc.  $\text{HNO}_3$  on ( $\alpha$ )-dichlorotoluene (Seelig, *A.* 237, 163). Long needles (from methyl alcohol).

( $\alpha$ )-Di-chloro-di-nitro-toluene  $\text{C}_6\text{H}_2(\text{CH}_3)\text{Cl}_2(\text{NO}_2)_2$  [1:3:3:7:7]. [122°]. Formed by the action of  $\text{HNO}_3$  (2 pts.) and  $\text{H}_2\text{SO}_4$  (1 pt.) on ( $\alpha$ )-di-chloro-toluene (10 pts.) (Seelig, *A.* 237, 163). Needles (from methyl alcohol). Yields on reduction a diamine which is apparently meta.

( $\beta$ )-Di-chloro-di-nitro-toluene  $\text{C}_6\text{H}_2(\text{CH}_3)\text{Cl}_2(\text{NO}_2)_2$  [1:2:4:5:6]. [102°]. Formed by the action of a mixture of  $\text{HNO}_3$  (2 pts.) and  $\text{H}_2\text{SO}_4$  (1 pt.) on ( $\beta$ )-chloro-toluene (10 pts.) (Seelig, *A.* 237, 163). Needles.

( $\alpha$ )-Tri-chloro-nitro-toluene  $\text{C}_6\text{H}_2(\text{CH}_3)\text{Cl}_3(\text{NO}_2)$ . [92°]. S. (alcohol) 4.5 at 20° (Schultz, *A.* 187, 277). Formed by dissolving ( $\alpha$ )-trichlorotoluene in conc.  $\text{HNO}_3$  (Seelig, *A.* 237, 139; *B.* 18, 422; Beilstein & Kuhlberg, *A.* 152, 240). Colourless plates (from alcohol).

( $\beta$ )-Tri-chloro-nitro-toluene  $\text{C}_6\text{H}_2(\text{CH}_3)\text{Cl}_3(\text{NO}_2)$ . [60°]. Formed by dissolving ( $\beta$ )-trichlorotoluene in conc.  $\text{HNO}_3$  (Seelig, *A.* 237, 140). Long yellow needles.

( $\alpha$ )-Tri-chloro-di-nitro-toluene  $\text{C}_6\text{H}(\text{CH}_3)\text{Cl}_3(\text{NO}_2)_2$ . [267°]. Formed by warming ( $\alpha$ )-trichlorotoluene with a mixture of conc.  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  (Schultz, *A.* 187, 280; Seelig, *A.* 237, 140; *B.* 18, 422). White plates or needles; v. sl. sol. alcohol. Reduced by tin and  $\text{HCl}$  to tri-chloro-tolylene-*p*-diamine.

( $\beta$ )-Tri-chloro-di-nitro-toluene  $\text{C}_6\text{H}(\text{CH}_3)\text{Cl}_3(\text{NO}_2)_2$ . [141°]. Formed by warming ( $\beta$ )-trichlorotoluene with a mixture of conc.  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  (Seelig, *A.* 237, 140; *B.* 18, 422). Light yellow needles, sl. sol. alcohol. Alcoholic  $\text{NH}_3$  at 100° gives tri-chloro-nitro-toluidine [191°].

**CHLORO-NITRO-TOLUENE SULPHONIC ACID**  $\text{C}_6\text{H}_4\text{Cl}(\text{NO}_2)\text{SO}_3\text{H}$ , i.e.  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}(\text{NO}_2)(\text{SO}_3\text{H})$ . From liquid ( $\alpha$ )-chloro-nitro-toluene and fuming sulphuric acid (Wroblewsky, *A.* 168, 204).— $\text{Ba}^{++}$ , 4aq; needles, sl. sol. water.

( $\alpha$ )-**TRI-CHLORO-NITRO-TOLUIDINE**  $\text{C}_6\text{H}_2(\text{CH}_3)\text{Cl}_3(\text{NH}_2)$ . [191°]. Formed by the action of alcoholic  $\text{NH}_3$  upon tri-chloro-di-nitro-toluene [227°] (Seelig, *B.* 18, 423; *A.* 237, 140). Orange-yellow needles (from alcohol).

( $\beta$ )-Tri-chloro-nitro-toluidine  $\text{C}_6\text{H}(\text{CH}_3)\text{Cl}_3(\text{NH}_2)$ . [192°]. Formed by the action of alcoholic  $\text{NH}_3$  upon tri-chloro-di-nitro-toluene [141°] (Seelig, *B.* 18, 423). Orange-red needles (from alcohol).

**TRI-CHLORO-DI-NITRO-DI-TOLYL-ETHANE**  $\text{C}_{12}\text{H}_8\text{Cl}_3(\text{NO}_2)_2$ . [122°]. From tri-chloro-di-tolyl-ethane  $(\text{C}_6\text{H}_4)_2\text{CH}_2\text{CH}_2\text{CH}_2$  and

fuming  $\text{HNO}_3$  (O. Fischer, *B.* 7, 1191). Short yellowish prisms.

**DI-*o*-CHLORO-NITRO-XYLENE**  $\text{C}_8\text{H}_6(\text{NO}_2)_2(\text{CH}_2\text{Cl})_2$ . [45°]. From di-*o*-chloro-*p*-xylene and fuming  $\text{HNO}_3$  (Grimaux, *Z.* 1871, 598). Small plates. V. sol. ether.

**Di-chloro-di-nitro-xylene**  $\text{C}_8\text{H}_4(\text{CH}_3)_2\text{Cl}_2(\text{NO}_2)_2$  [225°]. Formed by nitrating di-chloro-*p*-xylene (Kluge, *B.* 18, 2093). Needles.

**CHLORO-OCTANE** v. **OCTYL CHLORIDE**. Di-chloro-octane  $\text{C}_8\text{H}_{17}\text{Cl}_2$ , i.e.  $\text{C}_8\text{H}_{15}\text{CCL}_2\text{OH}$ , (c. 195°). From methyl hexyl ketone and  $\text{PCl}_5$  (Dachauer, *A.* 106, 271).

Di-chloro-octane  $\text{C}_8\text{H}_{17}\text{Cl}_2$ . (c. 199°). From  $\text{Cl}$  and the octylene from castor oil (D.; cf. Béhal, *Bl.* [2] 47, 33).

Di-chloro-octane  $\text{C}_8\text{H}_{17}\text{Cl}_2$ . (c. 235°). Formed by the action of  $\text{Cl}$  on a mixture of octylene and octane derived from paraffin (Thorpe & Young, *A.* 165, 16).

**CHLORO-OCTYL ALCOHOL**  $\text{C}_8\text{H}_{17}\text{ClO}$ . S.G. 1.003;  $d_{20}^{20}$  0.937. From octylene and very dilute (3 p.c.) aqueous  $\text{HOCl}$  (De Clermont, *Z.* 1870, 411). Oil.

**CHLORO-OCTYL-BENZENE**  $\text{C}_8\text{H}_7(\text{C}_6\text{H}_5)\text{Cl}$ . (270°–275°). Formed by chlorination of octylbenzene in presence of a trace of iodine. Oil. V. sol. alcohol and ether, insol. water (Ahrens, *B.* 19, 2719).

**CHLORO-OPICNIC ACID** v. **OPICNIC ACID**. **TRI-CHLORO-ORCIN** (?)  $\text{C}_6\text{H}_3\text{Cl}_3\text{O}_2$ , i.e.  $\text{C}_6(\text{CH}_3)_3\text{Cl}_3(\text{OH})_2$ . [59°]. From orcin and  $\text{Cl}$  (Schunck, *A.* 64, 271) or  $\text{HCl}$  and  $\text{KClO}_4$  (De Luynes, *A.* 130, 84). Slender needles.

Tri-chloro-orcin  $\text{C}_6(\text{CH}_3)_3\text{Cl}_3(\text{OH})_2$ . [123°]. From the pentachloride,  $\text{HI}$ , and phosphorus (Stenhouse, *Tr.* 1848, 88; *Pr.* 20, 72). Needles (from water) or plates (from  $\text{HOAc}$ ), m. sol.  $\text{CS}_2$ , m. sol. benzene, v. c. sol. alcohol and ether. Volatile with steam.  $\text{HIAg}$  and phosphorus at 180° convert it into orcin.  $\text{K}_2\text{FeO}_4$  oxidises it to di-chloro-oxy-tolquinone [157°].

Penta-chloro-orcin  $\text{C}_6(\text{CH}_3)_3\text{Cl}_5(\text{OCl})_2$ , or  $\text{C}_6(\text{CH}_3)_3\text{Cl}_5(\text{Cl})_2\text{O}_2$ . [120–5°]. According to Stenhouse, this, and not tri-chloro-orcin, is formed by treating orcin with  $\text{KClO}_4$  and  $\text{HCl}$ . Prisms (from  $\text{CS}_2$ ). M. sol.  $\text{CS}_2$  and benzene, v. sol. ether. Boiling water or alcohol decompose it with formation of tri-chloro-orcin. Liberates iodine from  $\text{KI}$ , and gives a pp. of  $\text{AgCl}$  with  $\text{AgNO}_3$  (Liebermann & Dittler, *A.* 100, 265).

Compound  $\text{C}_6(\text{CH}_3)_3\text{Cl}_5(\text{OCl})\text{HClO}$ . [140–5°]. From orcin, calcium hypochlorite, and  $\text{HCl}$ . Prisms (from benzene). V. sol. ether, sl. sol.  $\text{CS}_2$ . Converted by  $\text{NH}_3$  into  $\text{C}_6\text{H}_3\text{Cl}_3\text{NO}$  [187°] (Stenhouse, *B.* 6, 576).

**CHLORO-OXALAMYLNE** v. **CHLORO-ISO-BUTYL-ISOAMYL-GLYOXALINE**.

**CHLORO-OXALETHYLNE** v. **CHLORO-METHYL-ETHYL-GLYOXALINE**.

**CHLORO-OXALMETHYLNE** v. **CHLORO-METHYL-GLYOXALINE**.

**CHLORO-OXALPROPYLNE** v. **CHLORO-ETHYL-PROPYL-GLYOXALINE**.

**CHLORO-OKETHOSE**  $\text{C}_8\text{Cl}_2\text{O}$ . (210°). S.G. 1.652. Formed from alcoholic  $\text{K}_2\text{S}$  and perchlorinated ether:

$\text{C}_2\text{Cl}_4\text{O} + 2\text{K}_2\text{S} = 4\text{KCl} + \text{S}_2 + \text{C}_8\text{Cl}_2\text{O}$  (Malaguti, *A. Ch.* [8] 16, 19). Oil; smells like meadow-sweet. Has a sweet taste.

**Reactions**.—1. In sunlight it re-combines

with chlorine  $\text{C}_2\text{Cl}_4 + 2\text{Cl}_2 = \text{C}_2\text{Cl}_6 + \text{O}_2$ . Chlorine water forms trichloroacetic acid.

**CHLORO-OXIMIDO-ACETIC ETHER** v. **CHLORO-MONOTRORO-ACETIC ETHER**.

**CHLORO-OXINDOLE** v. **OXINDOLE**.

**Chloro-oxindole chloride** v. **Di-chloro-oxindole**.

**CHLORO-DI-OXY-ACETIC ACID** *Chloro-glyoxylic acid*.

*Diethyl derivative of the Nitrile*  $\text{ClO}(\text{OEt})_2\text{CN}$ . (a. 160°). Obtained, impure, from  $\text{COCl}(\text{OEt})\text{CN}$  and  $\text{NaOEt}$  (Bauer, A. 229, 176). Polymerises.

*Dipropyl derivative of the Nitrile*  $\text{ClO}(\text{OPr})_2\text{CN}$ . (a. 51°). From  $\text{COCl}(\text{OPr})\text{CN}$  and  $\text{NaOPr}$ . Polymerises.

**TETRA-CHLORO-TETRA-OXY-ADIPIC ETHER**. *Anhydride*  $\text{C}_4\text{H}_2\text{Cl}_8\text{O}_4$ , i.e.  $\text{EtO}_2\text{C}\cdot\text{O}\cdot\text{COCl}\cdot\text{CO}\cdot\text{COCl}\cdot\text{CO}_2\text{Et}$ . *Oxallyl-di-chloro-acetic ether*. [93°]. Formed by the action of chloroacetic acid on di-oxy-quinone-di-carboxylic ether. Highly greenish prisms. By hot alcoholic  $\text{NH}_3$  it is split up into 1 mol. of oxamide and 2 mols. of di-chloro-acetamide (Hantzsch a. Lowy, B. 19, 26, 3886; Hantzsch a. Zeckendorf, B. 20, 1808).

**DI-CHLORO-DI-OXY-DI-AMIDO-BENZENE** v. **DI-CHLORO-DI-AMIDO-HYDROQUINONE**.

**DI-CHLORO-DI-OXY-AMIDO-PYRIDINE**  $\text{C}_5\text{H}_3\text{Cl}_2\text{O}_2\text{N}$ , probably  $\text{N} \begin{smallmatrix} \text{C}(\text{OH})=\text{CCl} \\ \text{C}(\text{OH})-\text{CCl} \end{smallmatrix} \text{C.NH}_2$ .

*Di-chloro-glutazina*. [242°]. Formed in small quantity, together with tri-chloro-oxy-amido-pyridine, tri-chloro-amido-pyridine, and tetra-chloro-amido-pyridine, by heating glutazina with  $\text{PCl}_5$  (6 or 7 pts.). Short flat colourless needles. Sl. sol. hot water and alcohol. Dissolves readily in aqueous acids and alkalis. Combines with bromine (Stokes a. Pechmann, B. 19, 2710; Am. 8, 891).

*Di-ethyl derivative*  $\text{N} \begin{smallmatrix} \text{C}(\text{OEt})=\text{CCl} \\ \text{C}(\text{OEt})-\text{CCl} \end{smallmatrix} \text{C.NH}_2$ : [96°]. Long colourless needles. Readily sublimable. Volatile with steam. V. sol. alcohol and ether, insol. water. Formed together with the mono-ethyl derivative by heating tetra-chloro-amido-pyridine with an excess of sodium ethylate at 190° for 8 or 4 hours.

*Mono-ethyl derivative*  $\text{N} \begin{smallmatrix} \text{C}(\text{OH})=\text{CCl} \\ \text{C}(\text{OEt})-\text{CCl} \end{smallmatrix} \text{C.NH}_2$ : [162°]. Flat needles. Sublimable. Not volatile with steam. V. sol. alcohol and ether, sl. sol. hot water. Dissolves in alkalis, but not in dilute acids. It is also formed by heating tri-chloro-oxy-amido-pyridine with sodium ethylate.—A. Na: glistening rhombic tables (Stokes a. Pechmann, B. 19, 2710; Am. 8, 896).

**TRI-CHLORO-OXY-AMIDO-PYRIDINE**  $\text{C}_5\text{H}_2\text{Cl}_3\text{O}$  probably  $\text{N} \begin{smallmatrix} \text{C}(\text{OH})=\text{CCl} \\ \text{CCl}-\text{CCl} \end{smallmatrix} \text{C.NH}_2$ .

[283°]. Formed, together with an equal quantity of tetra-chloro-amido-pyridine and small quantities of di-chloro-di-oxy-amido-pyridine and tri-chloro-amido-pyridine, by heating glutazina with  $\text{PCl}_5$  (6 to 7 pts.). Flat colourless needles. Sublimable. V. sol. hot water, nearly insol. cold, m. sol. hot alcohol, sl. sol. cold, sl. sol. ether and benzene, insol. ligroin. Monobasic acid, decomposes soluble carbonates. Dissolves in conc.  $\text{HCl}$  or conc.  $\text{H}_2\text{SO}_4$ , but is re-

precipitated on dilution.—A. Na: needles, m. sol. cold water.

*Ethyl derivative*  $\text{N} \begin{smallmatrix} \text{C}(\text{OEt})=\text{CCl} \\ \text{CCl}-\text{CCl} \end{smallmatrix} \text{C.NH}_2$ : [82°]. Colourless needles. Very volatile with steam. Peculiar odour. V. sol. alcohol, ether, etc. Formed by ethylation of the above, or by heating tetra-chloro-amido-pyridine with sodium ethylate (Stokes a. Pechmann, B. 19, 2710; Am. 8, 892).

**$\gamma$ -CHLORO-o-OXY-ANGELIC ACID**  $\text{C}_5\text{H}_7\text{ClO}_4$ , i.e.  $\text{CH}_2\text{Cl}\cdot\text{CH}(\text{OH})\cdot\text{CH}(\text{OH})\cdot\text{CO}_2\text{H}$ . [116°]. From tri-chloro-oxy-valeric acid, zinc, and  $\text{HCl}$  (Pinner a. Bischoff, A. 179, 100; Pinner a. Klein, B. 11, 1496). V. sol. water, alcohol, and ether, sl. sol.  $\text{CS}_2$ . Combines with  $\text{Be}$   $\text{PCl}_5$  gives  $\text{CH}_2\text{Cl}\cdot\text{CH}(\text{OH})\cdot\text{CHCl}\cdot\text{COCl}$ .— $\text{ZnA}^+$ .— $\text{CuA}^+$ .— $\text{AgA}^+$ : needles, m. sol. cold water.

*Ethyl ether EtA*. [280°].

*Isobutyl ether*  $\text{CH}_3\text{PrA}$ . (a. 238°). **CHLORO-DI-OXY-ANTHRAQUINONE**  $\text{C}_{14}\text{H}_6\text{Cl}_2\text{O}_4$ . *Chloro-alizarin*. [246°-248°]. Prepared by the action of  $\text{Cl}$  on a cold solution of alizarin in  $\text{CS}_2$  (Diehl, B. 11, 187). Sublimes in red needles. Sol. boiling, sl. sol. cold, water.

*Di-chloro-di-oxy-anthraquinone*  $\text{C}_{14}\text{H}_4\text{Cl}_4\text{O}_4$ . *Di-chloro-alizarin*. [208°-310°]. Prepared by the action of  $\text{SbCl}_5$  on alizarin (Diehl, B. 11, 188). Sublimes in beautiful orange-red spikes. Combines with mordants readily, the colours resembling those produced by nitro-alizarin.

*Tetra-chloro-di-oxy-anthraquinone*  $\text{C}_{14}\text{H}_2\text{Cl}_6\text{O}_4$ . *Tetra-chloro-alizarin*. [a. 260°]. Prepared by the action of  $\text{SbCl}_5$  on alizarin (Diehl, B. 11, 189). Further action of  $\text{SbCl}_5$  forms  $\text{C}_6\text{Cl}_4$ ,  $\text{C}_6\text{Cl}_3$ ,  $\text{CCl}_4$ , and  $\text{CO}_2$ . Reddish-brown crystalline powder. Does not combine with mordants.

**CHLORO-OXY-BENZAMIDE** v. **AMIDE OF CHLORO-OXY-BENZOIC ACID**.

**DI-CHLORO-TETRA-OXY-BENZENE**  $\text{C}_6\text{Cl}_4(\text{OH})_4$ . *Hydrochloranilic acid*. From di-chloro-di-oxy-quinone by reduction with aqueous  $\text{SO}_2$  at 100°, or with tin and  $\text{HCl}$  (Koch, Z. 1868, 203; Graebe, A. 146, 82). Needles. V. sol. water, alcohol, and ether. Oxidised by moist air into di-chloro-di-oxy-quinone (chloranilic acid). *Tetra-acetyl derivative*  $\text{C}_6\text{Cl}_4(\text{OAc})_4$ . [235°].

**CHLORO-o-OXY-BENZOIC ACID**  $\text{C}_7\text{H}_5\text{ClO}_4$ , i.e.  $\text{C}_6\text{H}_4\text{Cl}(\text{OH})\cdot\text{CO}_2\text{H}$  [5:2:1]. *Chloro-salicylic acid*. Mol. w. 175.5. [172-5°] (H. a. B.); [169°] (V.). S. 0.9 at 20°; 1.25 at 100°.

*Formation*.—1. By passing the calculated quantity of chlorine into salicylic acid dissolved in a large quantity of  $\text{CS}_2$  (Hübner a. Brenken, B. 6, 174; cf. Cahours, A. Ch. [3] 18, 106), or in  $\text{HOAc}$  (Smith, B. 11, 1296; Maphall, A. Ch. S. 17, 476).—2. From (5,2,1)-chloro-amido-benzoic acid by displacement of  $\text{NH}_2$  by  $\text{OH}$  through the diazo-reaction (Hübner a. Weiss, B. 6, 176).—3. From (2,5,1)-oxy-amido-benzoic acid by displacement of  $\text{NH}_2$  by  $\text{Cl}$  (Schmitt, Z. 1864, 821; Beilstein, B. 8, 816).—4. From *p*-chloro-phenol,  $\text{CCl}_4$ , and alcoholic  $\text{KOH}$  (Hasse, Z. 16, 2196).—5. From  $\text{C}_6\text{H}_4\text{Cl}(\text{ONa})$  [1:4] and  $\text{CO}_2$  at 160° (Varnholt, J. pr. [2] 86, 20).

*Properties*.—Needles (from water). V. sol. alcohol, ether, and benzene.  $\text{FeCl}_3$  colours its aqueous solution red.

**Salts.**— $\text{NaA'}$ .— $\text{LiA'}$  2aq.— $\text{KA'}$ .— $\text{BaA'}$ , 8aq.— $\text{CaA'}$ , 8aq.— $\text{PbA'}$ .— $\text{CnA'}$ .— $\text{AgA'}$ .

**Methyl ether**  $\text{MeA'}$ . [48°]. (249°). Needles.

**Ethyl ether**  $\text{EtA'}$ . [110°]. Needles.

**Acetyl derivative**  $\text{C}_6\text{H}_5\text{Cl}(\text{OAc})\text{CO}_2\text{H}$  [149°].

**Amide**  $\text{C}_6\text{H}_5\text{Cl}(\text{OH})(\text{CONH}_2)$ . [228°].

**Chloro-oxy-benzoic acid**  $\text{C}_6\text{H}_4\text{Cl}(\text{OH})\text{CO}_2\text{H}$  [3:2:1]. [178°]. S. 0.8 at 3.5°. From [2:1]  $\text{C}_6\text{H}_4\text{Cl}(\text{ONa})$  and  $\text{CO}_2$  at 150° (Varnholt, *J. pr.* [2] 86, 22). Long needles, volatile with steam, may be sublimed. V. sol. alcohol and chloroform.  $\text{FeCl}_3$  gives a violet colour.— $\text{NaA'}$ .— $\text{BaA'}$ , 8aq.

**Methyl ether**  $\text{MeA'}$ . [83°]. (260°). Needles.

**Chloro-oxy-benzoic acid**  $\text{C}_6\text{H}_4\text{Cl}(\text{OH})\text{CO}_2\text{H}$  [4:2:1]. [207°]. From  $\text{C}_6\text{H}_4\text{Cl}(\text{ONa})$  [1:3] by treatment with  $\text{CO}_2$  and heating the product,  $\text{C}_6\text{H}_4\text{Cl}(\text{O.CO}_2\text{Na})$  at 150° (Varnholt, *J. pr.* [2] 86, 22). Also from  $\text{C}_6\text{H}_4\text{Cl}(\text{CO}_2\text{H})(\text{NO}_2)$  [1:2:4] by reduction, diazotisation, and boiling with water. Small needles, volatile with steam, may be sublimed. V. sol. alcohol and chloroform, al. sol. water.  $\text{FeCl}_3$  gives a violet colour.

**Chloro-p-oxy-benzoic acid**  $\text{C}_6\text{H}_3\text{Cl}(\text{OH})\text{CO}_2\text{H}$  [8:4:1]. [188°] (P.); [170°] (L.). S. 37 at c. 15°.

**Formation.**—1. From silver p-oxy-benzoate and Cl (Peltzer, *A.* 146, 284; *Z.* [2] 5, 225).—2. From p-oxy-benzoic acid and  $\text{SbCl}_3$  (Lössner, *J. pr.* [2] 13, 442).—3. From o-chlorophenol,  $\text{KOH}$ ,  $\text{OCl}_2$ , and alcohol at 130° (Hasse, *B.* 10, 2192).

**Properties.**—Silky needles; v. sol. hot water, f. a. sol. alcohol and ether. May be sublimed.  $\text{FeCl}_3$  gives a reddish-brown pp. in neutral solutions.

**Salt.**— $\text{BaA'}$ , 8aq.

**Methyl derivative**  $\text{C}_6\text{H}_4\text{Cl}(\text{OMe})\text{CO}_2\text{H}$ . **Chloro-anisic acid**. [215°]. White glistening scales. Formed by oxidation of the methyl ether of chloro-p-cresol.— $\text{A'Ag}$ : sparingly soluble pointed plates.— $\text{A'Ba}$  3½aq: thin rectangular tables, soluble in hot water (Schall a. Dralle, *B.* 17, 2529).

**Chloro-p-oxy-benzoic acid**. **Methyl derivative**  $\text{C}_6\text{H}_3\text{Cl}(\text{OMe})\text{CO}_2\text{H}$ . **Chloro-anisic acid**. [176°] (O.); [180°] (L.). From anisic acid and Cl (Laurent, *B. J.* 23, 421; Cahours, *A. Ch.* 56, 812). Prisms or needles. May be sublimed. Insol. water, v. sol. alcohol and ether. Probably identical with the preceding.

**Di-chloro-o-oxy-benzoic acid**  $\text{C}_6\text{H}_2\text{Cl}_2(\text{OH})(\text{CO}_2\text{H})$ . **Di-chloro-salicylic acid**. [214°]. Prepared by leading Cl into an acetic acid solution of salicylic acid (Smith, *B.* 11, 1225; *A. Ph. S.* 17, 486; cf. Cahours, *A. Ch.* [3] 13, 106). Formed also by heating salicylic acid (1 mol.) with  $\text{SbCl}_3$  (8½ mola.) (Lössner, *J. pr.* [2] 13, 429). Small prisms (from dilute alcohol). Sl. sol. hot water. May be sublimed.

**Salts.**— $\text{A'Ba}$  8aq. Long needles, insol. cold water.— $\text{A'K}$ : soluble needles.— $\text{A'Na}$ : large soluble needles.— $\text{A'Mg}$ : small soluble crystals.

$\text{A'Ph}$ . Insoluble pp.

**Methyl ether**: [242°]; needles.

**Ethyl ether**: [47°]; needles.

**Iso-butyl ether**: [188°]; small needles.

**Amide**: [209°]; needles.

**Methyl derivative**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{OMe})\text{CO}_2\text{H}$  [104°]. From methyl-salicylic acid and Cl

(Procter, *J. Ph.* [3] 8, 275; Cahours, *A. Ch.* [3] 10, 848). Needles.

**Ethyl derivative**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{OEt})\text{CO}_2\text{H}$ . Needles (Cahours, *A. Ch.* [3] 27, 461).

**Di-chloro-p-oxy-benzoic acid**

$\text{C}_6\text{H}_3\text{Cl}_2(\text{OH})\text{CO}_2\text{H}$  [158° uncor.]. Formed by oxidation of di-chloro-p-cresol with  $\text{CrO}_3$  in acetic acid (Claus a. Riemann, *B.* 16, 1606). Sublimable. Long white needles. Sol. alcohol, ether, and hot water, nearly insol. cold water.— $\text{A'Na}$ : small needles, sol. water and alcohol.

**Di-chloro-p-oxy-benzoic acid**. **Methyl derivative**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{OMe})\text{CO}_2\text{H}$ . **Di-chloro-anisic acid** [196°]. Formed, together with tetra-chloro-quinone, by treating anisic acid with  $\text{HCl}$  and  $\text{KClO}_4$  (Reinecke, *B.* [2] 7, 177). Large needles (from alcohol); insol. water.

**CHLORO-O-OXY-BENZOIC ALDEHYDE**

$\text{C}_6\text{H}_3\text{ClO}$ , i.e.  $\text{C}_6\text{H}_3\text{Cl}(\text{OH})\text{CHO}$ . From salicylic aldehyde and Cl (Piria, *A.* 30, 169; Löwig, *B. J.* 20, 311). Tables (from alcohol). Insol. water. Combines with  $\text{NaHSO}_3$  (Bertagnini, *A.* 85, 196).  $\text{Ba}(\text{O.C}_6\text{H}_4\text{ClCHO})_2$ : powder. With  $\text{NH}_3$ , it forms yellow needles of  $(\text{C}_6\text{H}_3\text{Cl}(\text{OH})\text{CH})\text{N}_3$  (Piria, *A. Ch.* [2] 69, 809).

**Chloro-p-oxy-benzoic aldehyde**

$\text{C}_6\text{H}_3\text{Cl}(\text{OH})\text{CHO}$ . [149°]. From p-oxy-benzoic aldehyde and dry chlorine (Herzfeld, *B.* 10, 2196). Silky needles; v. sol. water, alcohol, and ether. Absorbs  $\text{NH}_3$  (2 mola.).  $\text{FeCl}_3$  gives a violet colour.

**CHLORO-OXY-BENZYL ALCOHOL**

$\text{C}_6\text{H}_3\text{ClO}$ , i.e.  $\text{C}_6\text{H}_3\text{Cl}(\text{OH})\text{CH}_2\text{OH}$ . **Chloro-saligenin**. From chloro-salicylic acid by hydrolysis by emulsin (Piria, *A.* 56, 60). Trimetric plates (from water). Turned blue by  $\text{FeCl}_3$ .

**CHLORO-β-OXY-BUTYRIC ACID**

$\text{CH}_3\text{CH}(\text{OH})\text{CHClCO}_2\text{H}$ . [83°]. Prepared by addition of hypochlorous acid ( $\text{ClOH}$ ) to α-crotonic acid (Melikoff, *B.* 16, 1270; *Bl.* [3] 41, 811; 47, 167; Pavloff, *Bl.* [2] 43, 115). Needles. V. sol. water.

**Reactions.**—1. By the action of alcoholic  $\text{KOH}$  it gives propylene-oxide-carboxylic (β-methyl-glycidic) acid

whence  $\text{HCl}$  forms the following acid.—2. Heating with  $\text{H}_2\text{SO}_4$  gives α-chloro-crotonic acid whence zinc and  $\text{H}_2\text{SO}_4$  produce crotonic acid.—3. Heating with  $\text{HCl}$  gives  $\text{CH}_3\text{CHClCHClCO}_2\text{H}$  [89°] (?) whence alcoholic  $\text{KOH}$  gives rise to  $\text{CH}_3\text{CH:CHClCO}_2\text{H}$  [98°].

**Salts.**— $\text{A'Zn}$ : extremely soluble tables.— $\text{A'Ca}$ : easily soluble amorphous powder.

**Chloro-oxy-butyric acid**  $\text{C}_4\text{H}_5\text{Cl}(\text{OH})\text{CO}_2\text{H}$  [82°].

**Formation.**—1. By the addition of hypochlorous acid ( $\text{ClOH}$ ) to iso-crotonic acid.—2. By the addition of  $\text{HCl}$  to propylene oxide-carboxylic acid.

**Properties.**—Long prisms. V. sol. water, alcohol and ether. By the action of alcoholic  $\text{KOH}$  it gives butyro-glycidic acid.

**Salts.**— $\text{A'Ca}$  4aq: easily soluble microscopic crystals.— $\text{A'Zn}$  2aq: trimetric crystals, al. sol. cold water (Melikoff, *B.* 16, 1268).

**Chloro-oxy-butyric acid**

$\text{CH}_3\text{CH}(\text{OH})\text{CH}_2\text{CO}_2\text{H}$ . Formed at the same time as the preceding by the union of  $\text{HOCl}$  with isocrotonic acid (Melikoff, *J. B.* 16, 541).

Liquid. Converted by alcoholic KOH into propylene oxide carboxylic ((γ)-methyl-glycidic)

Chloro-oxy-isobutyric acid

$\text{CH}_3\text{Cl.CMe}(\text{OH}).\text{CO}_2\text{H}$ . Chloro-acetonic acid. [107°]. (c. 233°).

**Formation.**—1. From chloro-acetone by treatment with HCN and saponification of the resulting nitrile (Bischoff, *B.* 5, 865).—2. From methacrylic acid and HOCl (Melikoff, *Bl.* [2] 41, 811; 43, 116).—3. From propylene oxide carboxylic acid ((α)-methyl-glycidic acid)

**Properties.**—Long prisms (from ether); v. sol. water. Converted by alcoholic KOH into propylene-oxide carboxylic acid.

**Salts.**— $\text{CaA}$ ,  $2\text{aq}$ .— $\text{ZnA}$ .

**Nitrile**  $\text{CH}_3\text{Cl.CMe}(\text{OH}).\text{CN}$ . From chloro-acetone, by boiling with alcohol and conc. aqueous HCN (B.). Oil. Split up by distillation into HCy and  $\text{C}_2\text{H}_5\text{ClO}$ .

Chloro-oxy-butyric acid. **Nitrile**  $\text{C}_2\text{H}_5\text{ClNO}$ . From epichlorhydrin and anhydrous HCy at 140° (Hörmann, *B.* 12, 23). Liquid, v. sol. water. Dilute HCl forms a liquid chloro-oxy-butyric acid.

Di-chloro-oxy-isobutyric acid  $\text{CHCl}_2\text{CMe}(\text{OH}).\text{CO}_2\text{H}$  [83°]. From its nitrile and HClAq at 100° (Bischoff, *B.* 8, 1334). Prisms.— $\text{AgA}$ .

**Ethyl ether EtA**. (c. 212°).

**Nitrile**  $\text{CHCl}_2\text{CMe}(\text{OH}).\text{CN}$ . From di-chloro-acetone and conc. aqueous HCy (B.). Liquid. Split up by distillation or by alkalis into HCy and di-chloro-acetone. Aqueous KCy forms crystalline  $(\text{C}_2\text{H}_5\text{ClO})_2\text{HCN}$  (Glutz a. Fischer, *J. pr.* [2] 4, 52).

Di-chloro-oxy-isobutyric acid  $(\text{CH}_2\text{Cl})_2\text{C}(\text{OH}).\text{CO}_2\text{H}$  [93°]. Obtained by boiling its nitrile for 12 hours with conc. HClAq (Grimaux a. Adam, *Bl.* [2] 36, 20). Deliquescent tables, v. sol. alcohol and ether. KCN converts it into a nitrile of citric acid  $(\text{CH}_3\text{CN})_2\text{C}(\text{OH}).\text{CO}_2\text{H}$ .

**Ethyl ether EtA**. (c. 228°). From *s*-di-chlorhydrin, chloroformic ether, and sodium amalgam (Kelly, *B.* 11, 2222). Conc. KOH produces glycerin.

**Nitrile**  $(\text{CH}_2\text{Cl})_2\text{C}(\text{OH}).\text{CN}$ . From *s*-di-chloro-acetone (50 g.) by digesting with HCy (20 g.), a little water, and alcohol 8 c.c.

Tri-chloro-oxy-isobutyric acid  $\text{CCl}_3\text{CMe}(\text{OH}).\text{CO}_2\text{H}$ . From tri-chloro-acetone by successive treatment with HCy and HCl (Bischoff, *B.* 8, 1339). Syrup.

**TRI-CHLORO-DI-OXY-DI-CYMYL-ETHANE**  $\text{C}_6\text{H}_5\text{Cl}_3\text{O}_2$ , *i.e.*  $\text{CCl}_3\text{CH}(\text{C}_6\text{H}_5)_2\text{O}_2$  [194°]. From thymol (2 mol.), chloral (1 mol.), and conc.  $\text{H}_2\text{SO}_4$  diluted with HOAc (Jaeger, *B.* 7, 1197; *J.* 81, 262). Monoclinic needles (containing HOEt). Insol. water. Alcohol and zinc dust form  $\text{CH}_2\text{OH}(\text{C}_6\text{H}_5)_2$  and  $\text{CH}_2\text{Cl}(\text{C}_6\text{H}_5)_2$ .

**CHLORO-OXY-ETHYL-AMIDO-PHENYL-ETHANE**  $\text{OCl}_2\text{CH}(\text{OH}).\text{C}_6\text{H}_4\text{NH}_2$  [98°]. From chloral hydrate and ethyl-aniline (Boessneck, *B.* 31, 783).

**Nitrosamine**  $\text{C}_6\text{H}_5\text{Cl}_2\text{N}(\text{NO})$  [188°].

(*P. y.* 3:1:2) **CHLORO-OXY-ETHYL-QUINOL**

the action of  $\text{PCl}_5$  upon aniline ethyl-malonate under benzene. Colourless needles. M. sol. alcohol (Kilian, *B.* 20, 1235).

**TRI-CHLORO-OXY-ETHYL-SUCCINIC ACID**

**Lactone**.  $\text{CCl}_3\text{CH}_2\text{CH}(\text{CO}_2\text{H}).\text{CH}_2\text{CO}_2\text{O}$ . **Tri-**

**chloro-methyl-peraconic acid**. [97°]. From chloral, sodium succinate and  $\text{Ac}_2\text{O}$  (Fittig, *B.* 20, 3179). Converted by baryta into barium isocitrate.

**DI-CHLORO-DI-OXY-HEXANE**.  $\text{C}_2\text{H}_5\text{Cl}_2\text{O}$ , *i.e.*  $\text{CH}_2\text{ClCH}(\text{OH}).\text{CH}_2\text{CH}_2\text{CH}(\text{OH}).\text{CH}_2\text{Cl}$ . (?) S.G. 1.4. From diallyl and aqueous HOCl in the cold (Henry, *B.* 7, 416; *Z.* [2] 5, 479). Oil. Potash converts it into diallyl dioxide whence baryta-water produces the anhydride of tetra-oxy-hexane  $\text{C}_6\text{H}_{12}\text{O}_4$  (Przibytek, *Bl.* [2] 45, 248).

Di-chloro-tetra-oxy-hexane v. MANHITZ.

**DI-CHLORO-DI-OXY-HEXINOIC ACID**  $\text{C}_2\text{H}_5\text{Cl}_2\text{O}$ , *i.e.*  $\text{CH}_2\text{ClCH}(\text{OH}).\text{COCl}(\text{OH}).\text{CH}_2\text{CO}_2\text{H}$  (?). **Di-chloro-di-oxy-amenyl carboxylic acid**. [177°]. From the following by sodium amalgam (Hantzsch, *B.* 20, 2789). Lustrous prisms. Conc. aqueous NaOH forms  $\text{C}_2\text{H}_5\text{ClO}_2\text{Na}$ , 6aq which crystallises in canary yellow needles and is converted by HCl into  $\text{C}_2\text{H}_5\text{ClO}_2$  [97°], which forms a salt  $\text{NaA}$  8aq.— $\text{NH}_4\text{A}$ . [185°].

**Acetyl derivative** [134°].

**Tri-chloro-di-oxy-hexinoic acid**  $\text{C}_2\text{H}_5\text{Cl}_3\text{O}$ , *i.e.*  $\text{CH}_2\text{ClCH}(\text{OH}).\text{COCl}(\text{OH}).\text{COCl}(\text{OH}).\text{CH}_2\text{CO}_2\text{H}$  (?) [177°]. Formed, together with tri-chloro-phenol, by passing chlorine into an alkaline solution of phenol (Hantzsch, *B.* 20, 2789). The yield is 50 p.c. Needles (from water); or monoclinic crystals (containing 4aq). Decomposed by conc. aqueous KOH.— $\text{NH}_4\text{A}$  2aq: trimetric prisms, sl. sol. water.

**Methyl ether MeA**. [126°].

**Di-acetyl derivative**  $\text{C}_6\text{H}_5\text{Ac}_2\text{Cl}_2\text{O}_2$  [188°–192°].

**CHLORO-DI-OXY-INDONAPHTHENE**

**nylene-chloro-oxy-acetylene-ketone**. [114°].

Formed by the action of acids or alkalis upon

$\text{C}_6\text{H}_5 \begin{array}{c} \text{CO} \\ \diagdown \quad \diagup \\ \text{CCl} \end{array} \text{C.NHR}$ , which are obtained by the

action of amines upon di-chloro-oxy-indonaph-

thene (*q. v.*),  $\text{C}_6\text{H}_5 \begin{array}{c} \text{CO} \\ \diagdown \quad \diagup \\ \text{CCl} \end{array} \text{CCl}$ . If reconverted

into these amides by the action of amines (Zinke, *B.* 20, 1271). White glistening plates (from dilute alcohol), or small compact crystals (from petroleum-spirit). Dissolves in aqueous alkalis with a red colour. By  $\text{PCl}_5$  it is converted into the

**(In. 8:1:2)-Di-chloro-oxy-indonaphthene**

$\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{CCl} \end{array} \text{CO}$ . [125°]. Formed by the action of  $\text{PCl}_5$  upon chloro-di-oxy-indonaphthene  $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{C(OH)} \\ \diagdown \text{CCl} \end{array} \text{CO}$ . Glistening plates (from dilute alcohol) (Zincke, B. 20, 1972).

**(In. 8:2:1)-Di-chloro-oxy-indonaphthene**

$\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{CCl} \end{array} \text{CCl}$ . *Phenylene-di-chloro-acetyleneketone*. [90°]. Formed by oxidation of the car-

boxylic acid  $\text{C}_6\text{H}_4 \begin{array}{c} \text{C(OH).CO}_2\text{H} \\ \diagdown \text{CCl:CCl} \end{array}$  (from di-chloro-( $\beta$ )-naphthoquinone) with  $\text{CrO}_3$ . Small yellow or long glistening golden needles. Very volatile with steam. It has some of the characteristics of a quinone. With aromatic bases it forms coloured compounds. Reacts with hydroxylamine and with phenylhydrazine. With halogens it yields colourless addition-products. It is not affected by  $\text{SnCl}_2$  or by  $\text{PCl}_5$ .

*Methyl-amide*  $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{CCl} \end{array} > \text{C.NHMe}$  or

$\text{C}_6\text{H}_4 \begin{array}{c} \text{C(OH)} \\ \diagdown \text{CCl} \end{array} > \text{C.NMe}$ : [195°]; long dark-red needles, sol. hot alcohol and acetic acid, sl. sol. benzene.

*Di-methyl-amide*  $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{CCl} \end{array} > \text{C.CO.NMe}_2$ : [140°]; long red needles or thick tables.— $\text{B}^+ \cdot \text{H}_2\text{Cl}_2 \cdot \text{PtCl}_4$ : yellow crystalline pp.

*Anilide*  $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{CCl} \end{array} > \text{C.CO.NHPh}$ : [204°]; slender deep-red needles; dissolve in warm dilute alkalis without decomposition.

*Oxim*  $\text{C}_6\text{H}_4 \begin{array}{c} \text{C(OH)} \\ \diagdown \text{CCl} \end{array} > \text{CCl}$ : [120°]; long yellow needles; v. sol. warm alcohol and acetic acid (Zincke, B. 20, 1265).

*Dichloride*  $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{CCl} \end{array} > \text{CCl}_2$ . [108°]. Converted by aqueous  $\text{NaOH}$  into tri-chloro-vinyl-benzoic acid [168°] (Zincke & Fröhlich, B. 20, 2053).

*Di-bromide*  $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{CClBr} \end{array} > \text{CClBr}$ . [114°], and, when rapidly heated, [c. 128°]. Converted by aqueous  $\text{NaOH}$  into di-chloro-bromo-vinyl-benzoic acid  $\text{CClBr} \cdot \text{CCl} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$  [174°].

**Chloro-oxy-indonaphthalene dichloride**

$\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{CHCl} \end{array} > \text{CCl}_2$ . [59°]. From the dihydride of tri-chloro-di-oxy-indonaphthene carboxylic acid and dilute  $\text{CrO}_3\text{Aq}$  (Zincke, B. 20, 2890). Thick needles (from alcohol). Converted by alkalis into di-chloro-vinyl-benzoic acid.

**DI-CHLORO-DI-OXY-INDONAPHTHENE**

$\text{C}_6\text{H}_4 \begin{array}{c} \text{C(OH).CO}_2\text{H} \\ \diagdown \text{CCl} \end{array}$   
**CARBOXYLIC ACID**  $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{CCl} \end{array} > \text{CCl}_2$ . [189°].

Formed by dissolving the hydrate of tetra-chloro-( $\beta$ )-naphthoquinone in dilute  $\text{Na}_2\text{CO}_3\text{Aq}$  and ppg. with an acid (Zincke, B. 21, 497). Thick needles (containing aq. from water). V. sol. alcohol, benzene, and  $\text{HOAc}$ .  $\text{CrO}_3$  gives  $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO} \\ \diagup \text{CCl} \end{array} > \text{CCl}_2$  [124°].

*Methyl ether MeA'* [124°] large oblique crystals.

**Acetyl derivative  $\text{C}_6\text{H}_4\text{AcClO}_2$ . [126°].****Prisms.**

Tri-chloro-oxy-indonaphthene carboxylic acid. *Dihydride*  $\text{C}_6\text{H}_4\text{Cl}_2\text{O}_2$ , i.e.

$\text{C}_6\text{H}_4 \begin{array}{c} \text{C(OH).CO}_2\text{H} \\ \diagdown \text{CHCl} \end{array} > \text{CCl}_2$ . From the dihydride of di-

chloro-( $\beta$ )-naphthoquinone  $\text{C}_6\text{H}_4 \begin{array}{c} \text{CO.CO} \\ \diagdown \text{CHCl.CCl}_2 \end{array}$  and dilute  $\text{NaOH}$  (Zincke & Fröhlich, B. 20, 2894). Liquid.

**Methyl ether MeA'. [150°].**

*Acetyl derivative of the methyl ether*  $\text{C}_6\text{H}_4\text{MeAcClO}_2$ . [116°].

**DI-CHLORO-OXY-METHANE SULPHINIC ACID**  $\text{CCl}_2(\text{OH})\text{SO}_2\text{H}$ . Unstable deliquescent needles.

**Salt.**—A.K. Trimetric plates. From  $\text{KCy}$  and aqueous or alcoholic trichloro-methane sulphochloride (q.v.):  $\text{CCl}_2\text{SO}_2\text{Cl} + \text{KC}_y + \text{H}_2\text{O} = \text{CyCl} + \text{HCl} + \text{CCl}_2(\text{OH})\text{SO}_2\text{K}$ . Boiled with potash it forms  $\text{KCl}$  and  $\text{K}_2\text{SO}_4$  (Loew, Z. 1868, 518; McGowan, J. pr. [2] 30, 288).

**DI-CHLORO-OXY-METHANE SULPHONIC ACID.**

**Chloride.**— $\text{CCl}_2(\text{OH})\text{SO}_2\text{Cl}$ . From  $\text{PCl}_5$  and  $\text{CCl}_2(\text{OH})\text{SO}_2\text{K}$  (McGowan, J. pr. [2] 30, 289).

**Anilide.**— $\text{CCl}_2(\text{OH})\text{SO}_2\text{NPhH}$ . Rhombohedra. From aniline and the above chloride.

**TRI-*o*-CHLORO-*o*-OXY-METHYL-AMIDO-PHENYL-ETHANE**  $\text{OCl}_2\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{NHMe}$ . [112°]. From chloral hydrate and methyl-aniline (Boessneck, B. 21, 782).

**Nitrosamine**  $\text{OCl}_2\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{NMeNO}$ . [118°]. Needles.

**Tri-*o*-chloro-*o*-oxy-di-methyl-amido-benzene**  $\text{CCl}_2\text{CH}(\text{OH})\text{C}_6\text{H}_4\text{NHMe}_2$ . Formed by condensation of chloral hydrate with di-methyl-aniline in presence of  $\text{ZnCl}_2$  (Knöfler & Boessneck, B. 20, 3193).

**(Py. 3:1)-CHLORO-OXY-(B. 4)-METHYL-(Py. 2)-ETHYL-QUINOLINE**

$\text{C}_6\text{H}_4\text{Me} \begin{array}{c} \text{C(OH)-CEt} \\ \diagdown \text{N} \\ \diagup \text{CCl} \end{array}$

***o*-Chloro- $\beta$ -ethyl-*o*-oxy-*o*-toluquinoline.**

[225°]. Formed by the action of  $\text{PCl}_5$  upon *o*-toluidine ethyl-malonate under benzene. Silky needles (from alcohol) (Kiliani, B. 20, 1233).

**CHLORO-DI-OXY-METHYL-PURIN.****Methylethyl derivative**

$\text{C}_6\text{N}_4(\text{CH}_3)(\text{OMe})(\text{OEt})\text{Cl}$  (?) *Ethoxy-chloro-oxy-di-methyl-purin*. [160°]. Granular crystals. Formed by the action of a solution of  $\text{NaOH}$  in 50 p.c. alcohol on di-chloro-methoxy-methyl-purin. By  $\text{HCl}$  at 180° it is converted into tri-oxy-di-methyl-purin (di-methyl-uric acid). By  $\text{HI}$  it is reduced to di-oxy-di-methyl-purin (Fischer, B. 17, 836).

**Di-ethyl derivative  $\text{C}_6(\text{CH}_3)(\text{OEt})_2\text{OIN}$ .**

Formed by heating tri-chloro-methyl-purin with alcoholic  $\text{NaOH}$  (Fischer, B. 17, 832). Fine felted needles. Heated with  $\text{HCl}$  at 180° it gives methyl-uric acid (tri-oxy-methyl-purin).

**Di-chloro-oxy-methyl-purin  $\text{C}_6\text{H}_4\text{ONCl}_2$ , i.e.**

$\text{C}_6(\text{CH}_3)(\text{OH})\text{Cl}_2\text{N}$ , probably  $\text{C}_6\text{H}_4 \begin{array}{c} \text{N} \\ \diagup \text{O} \\ \diagdown \text{N} \end{array} \begin{array}{c} \text{O} \\ \diagup \text{NH} \\ \diagdown \text{C-NMe} \end{array} > \text{CO}$

[274°]. Obtained by heating methyl-uric acid with  $\text{PCl}_5$  and  $\text{POCl}_3$  at  $180^\circ$  (Fischer, B. 17, 330, 1786). Fine white needles. Very stable body, volatilising without decomposition and not being attacked by  $\text{HNO}_3$  or by  $\text{KClO}_4$  and  $\text{HCl}$ . By  $\text{HI}$  it is reduced to oxy-methyl-purin.

[189°]. Di-chloro-methoxy-methyl-purin. Formed by heating the lead compound of di-chloro-oxy-methyl-purin with methyl iodide (Fischer, B. 17, 334, 1787). Fine colourless needles. Insol. alkalis. By  $\text{HI}$  it is reduced to methoxy-methyl-purin.

(Py. 4, 8) - CHLORO-OXY - (B. 2) - METHYL-QUINOLINE  $\text{C}_8\text{H}_6\text{CH}_2\text{NOCl}$  i.e.  $\text{OMe}:\text{CH}:\text{O}:\text{CH}:\text{CH}$

$\text{CH}:\text{CH}:\text{C}:\text{N}:\text{Cl}:\text{CO}$  Chloro-methyl-pseudocarbostyryl. [121°]. Formed by treating a solution of (B. 2) methylquinoline in boric acid with bleaching powder solution (Emhorn a. Lauch, A. 248, 358). White needles (from acetic ether).

Reactions.—1. Boiled with  $\text{NaOH}$  aq (B. 2) methyl-carbostyryl [228°] is obtained.—2. Yields an isomeride [281°] on boiling with alcohol. (Py. 1, 5, 4) Chloro-oxy-methyl-quinoline

$\text{C}_8\text{H}_5\text{CH}_2\text{N}(\text{CO}:\text{CH})$  [117-5°]. From ( $\gamma$ )-chloro-carbostyryl,  $\text{MeI}$ , and alcoholic  $\text{NaOH}$  (Friedländer a. Müller, B. 20, 2009). Hair-like needles (from  $\text{MeOH}$ ).

(Py.) Chloro-di-oxy-(B. 2)-methyl-quinoline Di-ethyl derivatives  $\text{C}_8\text{H}_4(\text{CH}_3)_2\text{N}(\text{CO}:\text{CH})(\text{OEt})_2$  [71°]. Formed by heating (Py. 1:2:3)-tri-chloro-(B. 2)-methyl-quinoline with a solution of sodium in absolute alcohol at  $100^\circ$ - $130^\circ$ . Long colourless needles (Rügheimer a. Hoffmann, B. 18, 2982).

(Py. 2:3:1) Chloro-di-oxy-(B. 4)-methyl-quinoline  $\text{C}_8\text{H}_4\text{NClO}_2$  i.e.

styryl. [277°]. Formed by heating (Py. 2:3:1)-di-chloro-oxy-(B. 4)-methyl-quinoline with dilute  $\text{HCl}$  at  $160^\circ$ . Large plates or tables. V. sol. acetic acid, sl. sol. alcohol, insol. water. Dissolves in acids and alkalis (Rügheimer a. Hoffmann, B. 18, 2986).

(Py. 1) Chloro-(B. 2)-oxy-methyl-quinoline. Methyl derivatives  $\text{C}(\text{OMe}):\text{CH}:\text{C}:\text{Cl}:\text{CH}$

$\text{CH}=\text{CH}:\text{O}:\text{N}:\text{CMe}$  [100°] (a. 296°). From the corresponding  $\text{C}_8\text{H}_4\text{Me}(\text{OH})(\text{OMe})\text{N}$  by  $\text{POCl}_3$  (Conrad a. Lippach, B. 21, 1649). Silky prisms.

(Py. 1:2:3) Di-chloro-oxy-(B. 2)-methyl-quinoline  $\text{C}_8\text{H}_4\text{NClO}_2$  i.e.

Di-chloro-tolucarbostyryl. [292°]. Obtained by heating (Py. 1:2:3)-tri-chloro-(B. 2)-methyl-quinoline

line with dilute  $\text{HCl}$  at  $180^\circ$ . Small crystals. Sol. benzene and acetic acid, sl. sol. alcohol and ether, insol. water. Has both weak basic and weak acid properties (Rügheimer a. Hoffmann, B. 18, 2981).

(Py. 1:2:3) Di-chloro-oxy-(B. 4)-methyl-quinoline  $\text{C}_8\text{H}_4(\text{CH}_3)_2\text{N}(\text{CO}:\text{CH})$  i.e.

tolucarbostyryl. [288°]. Formed by heating (Py. 1:2:3)-tri-chloro-(B. 4)-methyl-quinoline with dilute  $\text{HCl}$  at  $180^\circ$ . Small white needles (from acetic acid). Sublimes in needles. Sl. sol. alcohol, insol. water (Rügheimer a. Hoffmann, B. 18, 2985).

(Py. 2:3:1) Di-chloro-oxy-(B. 4)-methyl-quinoline  $\text{C}_8\text{H}_4(\text{CH}_3)_2\text{N}(\text{CO}:\text{CH})$  i.e.

Formed by the action of  $\text{PCl}_5$  upon the acid malonate of o-toluidine in presence of cold benzene. Needles. Sl. sol. alcohol and acetic acid, nearly insol. water. Decomposes alkaline carbonates (Rügheimer a. Hoffmann, B. 18, 2983).

(Py. 2:4:3) - CHLORO-OXY-METHYL-ISO-QUINOLINE  $\text{C}_8\text{H}_4\text{ClNO}$  i.e.  $\text{C}_8\text{H}_4\text{CH}_2\text{N}(\text{CO}:\text{CH})$

[112°]. Formed by methylation of (Py. 2:4)-chloro-oxy-isoquinoline [226°]. Long needles. V. sol. ether, benzene, chloroform, and hot alcohol (Gabriel, B. 19, 2361).

(Py. 4:2:1) Chloro-oxy-methyl-isoquinoline  $\text{C}_8\text{H}_4\text{CH}_2\text{N}(\text{CO}:\text{CH})$  i.e.

Needles (from acetic acid). Sol. aqueous alkalis. Formed as a by-product of the reaction of  $\text{POCl}_3$  upon the imide of phenyl-methyl-acetic-carboxylic acid  $\text{C}_8\text{H}_4\text{CH}_2\text{N}(\text{CO}:\text{CH})$  (Gabriel, B. 20, 2504).

CHLORO-OXY-(a)-NAPHTHOQUINONE  $\text{C}_{10}\text{H}_6\text{ClO}_2$  i.e.  $\text{C}_{10}\text{H}_6\text{Cl}(\text{OH})\text{O}$ . Chloro-naphthalic acid. [above  $200^\circ$ ]. Formed by boiling chloro-naphthalene tetrachloride with  $\text{HNO}_3$  (Laurent, A. 35, 293). Formed also by boiling di-chloro-naphthoquinone with alcoholic  $\text{KOH}$  (Graebe, A. 149, 14; P. a. E. Depouilly, Bl. [2] 4, 10); and by boiling the alkylamides of chloro-(a)-naphthoquinone with acids or aqueous  $\text{KOH}$ . Yellow needles; may be sublimed. Insol. water, m. sol. alcohol and ether.  $\text{HNO}_3$  oxidises it to phthalic and oxalic acids. Turned red by alkalis. Distillation with  $\text{PCl}_5$  gives pentachloro-naphthalene.

Salts.— $\text{KCl}_2\text{H}_2\text{ClO}_2$ , aq; crimson needles.— $\text{BaA}$ , aq; silky orange needles.

Imide  $\text{C}_8\text{H}_4\text{CH}_2\text{N}(\text{CO}:\text{CH})$  i.e.

Formed by the action of alcoholic  $\text{NH}_3$  upon a hot alcoholic solution of chloro-( $\beta$ )-naphthoquinone. Dark metallic plates. Sl. sol. alcohol and acetic acid. Dissolves in dilute  $\text{NaOH}$  with a dark-violet colour. Long boiling with  $\text{HCl}$  yields chloro-oxy-(a)-naphthoquinone (Zincke, B. 19, 2499).

## 107.

$C_{10}H_7ClO_2(OH)(SO_3H)$ . From naphthalene,  $KClO_4$ , and  $H_2SO_4$  (Hermann, A. 151, 68; Z. [2] 4, 551). Amorphous mass, m. sol. water, v. sol. alcohol and ether. When boiled with water i

( $\text{C}_6\text{H}_5\text{Cl} \xrightarrow[\text{O}]{\text{NCl}}$  CO) of the action of bleaching

powder on  $\text{C}_6\text{H}_5\text{N} \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$  (Jacoby, *J. pr.* [2] 37, 82). Plates (from water, HOAc, and benzene). Sl. sol. hot water. May be sublimed.

*Neo-o*-di-chloro-oxy-phenyl-carbamic acid.

**Anhydride**  $\text{C}_6\text{H}_3\text{Cl}_2 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$ . (*a*)-*Carbonyl-di-chloro-phenol chlorimide*. [119°]. From the preceding and chlorine-water (Jacoby, *J. pr.* [2] 37, 40). Plates; m. sol. chloroform and benzene. Converted by heat into the following isomeride. Converted into the preceding body by boiling with alcohol, ether, water, aniline, di-methyl-aniline, and phenyl-hydrazine.

**Di-chloro-oxy-phenyl-carbamic acid. Anhydride**  $\text{C}_6\text{H}_3\text{Cl}_2 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$ . (*a*)-*Carbonyl-di-chloro-amido-phenol*. [270°]. The chief product of the action of heat on the preceding, the following isomeride being also formed (J.). Prisms (from alcohol). May be sublimed.

**Di-chloro-oxy-phenyl-carbamic acid. Anhydride**  $\text{C}_6\text{H}_3\text{Cl}_2 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$ . (*B*)-*Carbonyl-di-chloro-amido-phenol*. [214°]. Formed as above. Needles; v. e. sol. alcohol, ether, and HOAc; m. sol. water. Sublimes in needles.

**Tri-chloro-oxy-phenyl-carbamic acid. Anhydride**  $\text{C}_6\text{H}_2\text{Cl}_3 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$ . (*a*)-*Carbonyl-di-chloro-phenol chlorimide*. [c. 147°]. From  $\text{C}_6\text{H}_3\text{Cl}_3 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$  and a solution of bleaching-powder (Jacoby, *J. pr.* [2] 37, 46).

**Tri-chloro-oxy-phenyl-carbamic acid. Anhydride**  $\text{C}_6\text{H}_2\text{Cl}_3 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$ . [89°]. (*B*)-*Carbonyl-di-chloro-phenol chlorimide*. From  $\text{C}_6\text{H}_2\text{Cl}_3 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$  in HOAc by adding a solution of bleaching-powder (J.). Needles; sol. water.

**Tri-chloro-oxy-phenyl-carbamic acid. Anhydride**  $\text{C}_6\text{HCl}_2 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$ . *Carbonyl-tri-chloro-amido-phenol*. [262°]. Formed from  $\text{C}_6\text{H} \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$  in HOAc by chlorination and subsequent decomposition of the product by boiling alcohol (J.). Needles, sl. sol. alcohol, HOAc, and water. Sublimes in plates.

**Tetra-chloro-oxy-phenyl-carbamic acid. Anhydride**  $\text{C}_6\text{Cl}_4 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$ . *Carbonyl-tetra-chloro-amido-phenol*. [c. 222°]. Formed by heating  $\text{C}_6\text{HCl}_3 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$  which is obtained by treating a solution of the preceding in HOAc with bleaching-powder (Jacoby, *J. pr.* [2] 37, 48). White crystalline sublimate; sl. sol. water; m. sol. alcohol and HOAc; v. sol. ether and benzene. Converted by bleaching-powder solution into  $\text{C}_6\text{Cl}_4 \begin{smallmatrix} \text{NH} \\ \diagup \text{O} \end{smallmatrix} \text{CO}$  whence it is regenerated by boiling with alcohol.

**TRI-CHLORO-DI-OXY-DE-PHENYL-ETHANE**  $\text{C}_6\text{H}_2\text{Cl}_3\text{O}_2$ , i.e.  $\text{OCl} \cdot \text{CH}(\text{C}_6\text{H}_2\text{Cl}_2) \cdot \text{OH}$ . [202°]. From phenol, chloral,  $\text{H}_2\text{SO}_4$ , and HOAc at 0° (see Moer, *B. 7*, 1201). Small crystals; v. sol. alcohol and ether. Alcohol and zinc-dust give  $\text{CH}_2\text{Cl} \cdot \text{C}(\text{C}_6\text{H}_2\text{Cl}_2) \cdot \text{OH}$ .

*Di-acetyl derivative*  
 $\text{OCl} \cdot \text{CH}(\text{C}_6\text{H}_2\text{OAc}) \cdot \text{OH}$ . [189°]. Needles.

**DI-CHLORO-OXY-PHENYL-METHYL-PYRAZOLE**  $\text{C}_6\text{H}_3\text{N}_2\text{OCl}_2$ , i.e.

$\text{Ph} \cdot \text{N} \begin{smallmatrix} \text{CO} \text{---} \text{CCl}_2 \\ \diagup \text{N} \text{---} \text{CMe} \end{smallmatrix}$ . [61°]. Obtained by passing chlorine into oxy-phenyl-methyl-pyrazole dissolved in chloroform (Knorr, *A.* 238, 178). Crystalline mass, volatile with steam, insol. water and alkalis, sol. alcohol and ether. Reduced by  $\text{Sn}$  and HCl to oxy-phenyl-methyl-pyrazole.

**β-CHLORO-(a)-OXY-PHENYL-PROPIONIC ACID**  $\text{C}_9\text{H}_7\text{ClO}_2$ , i.e.  $\text{Ph} \cdot \text{CH}(\text{OH}) \cdot \text{CHCl} \cdot \text{CO}_2\text{H}$  [104°]. From sodic cinchamate, sodic carbonate and chlorine (Glaser, *A.* 147, 80; 219, 188) or better, from potassium cinnamate and HClO (Erlenmeyer a. Lipp, *A.* 219, 184). Slender six-sided laminae (containing aq.). Melts, in the hydrated condition, at 80°. M. sol. cold water.

*Reactions*.—1. Alkalis form so-called β-oxy-phenyl-cinnamic acid which is probably the anhydride of αβ-di-oxy-phenyl-propionic acid

$\text{C}_6\text{H}_5 \cdot \text{CH} \begin{smallmatrix} \text{O} \\ \diagup \end{smallmatrix} \cdot \text{CH} \cdot \text{CO}_2\text{H}$  (Erlenmeyer, *B.* 20, 2465), and αβ-di-oxy-phenyl-propionic acid.—2. Sodium amalgam forms β-oxy-phenyl-propionic acid.—3. Fuming HCl produces αβ-di-chloro-phenyl-propionic acid.—4. Boiling with  $\text{As}_2\text{O}_3$  gives α-chloro-cinnamic acid.

*Salt*.— $\text{AgA}'$ : crystalline powder.

*α-Chloro-β-oxy-phenyl-propionic acid*  
 $\text{C}_6\text{H}_5 \cdot \text{CH}(\text{OH}) \cdot \text{CHCl} \cdot \text{CO}_2\text{H}$ . From αβ-di-oxy-phenyl-propionic acid and HCl (Leschhorn, *Dissert. Wurzburg*, 1884). Formed also by the

action of HCl on  $\text{C}_6\text{H}_5 \cdot \text{CH} \begin{smallmatrix} \text{O} \\ \diagup \end{smallmatrix} \cdot \text{CH} \cdot \text{CO}_2\text{H}$ , which is obtained by treating the preceding acid with alkalis (Erlenmeyer, *jun.*, *B.* 20, 2466).

*Chloro-oxy-α-phenyl-propionic acid*  $\text{C}_6\text{H}_5\text{ClO}_2$ . *Chloro-tropic acid*. [130°]. From atropic acid and aqueous ClOH (Ladenberg, *A.* 217, 110). Crystals; v. e. sol. water. Zinc-dust and iron filings in HOAc convert it into tropic acid.

(*Py.* 1:4:2). **CHLORO-OXY-PHENYL-ISO-QUINOLINE**  $\text{C}_{11}\text{H}_7\text{ClNO}$ , i.e.

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CCl} \cdot \text{CPh} \\ \diagup \text{CO} \cdot \text{NH} \end{smallmatrix}$  or  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CCl} \\ \diagup \text{C}(\text{OH}) \cdot \text{N} \end{smallmatrix}$ .

*Chloro-isobenzalphthalimidine*. [212°]. Formed by heating chloro-methoxy-phenyl-isquinoline [76°] with fuming HCl at 100°. Silky needles. V. sol. benzene, chloroform, and acetic acid, m. sol. cold alcohol and ether (Gabriel, *B.* 19, 2358).

*Methyl derivative*  $\text{C}_{11}\text{H}_8\text{NOCl}$ , i.e.

$\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CCl} \\ \diagup \text{C}(\text{OMe}) \cdot \text{N} \end{smallmatrix}$ . [76°]. Formed by heating

di-chloro-phenyl-isquinoline with a solution of sodium in methyl alcohol at 100°. Colourless needles. V. sol. ether, chloroform, benzene, and acetic acid. Very weak base. By heating with fuming HCl at 100° it yields chloro-oxy-phenyl-isquinoline (chloro-isobenzalphthalimidine) and methyl chloride (Gabriel, *B.* 19, 2357).

**TETRA-CHLORO-DI-OXY-DI-PHENYL-SULPHONE**  $C_{12}H_4Cl_4SO_2$ , i.e.  $SO_2(C_6H_4Cl_2OH)_2$ , [289°]. S.G. 1.777. From  $SO_2(C_6H_4OH)_2$ ,  $KClO_3$ , and  $HCl$  (Annheim, A. 172, 88; B. 9, 1150). Needles or prisms. Insol. water, v. sl. sol. cold alcohol.

**DI-CHLORO-DI-OXY-DI-PHENYL-THIOUREA**. *Di-methyl ether*  $SC(NH.C_6H_4Cl(OMe))_2$ , [153°]. From chloro-anisidine, alcohol, and  $CS_2$ . White needles, sol. alcohol and ether (Herold, B. 15, 1687).

**CHLORO-OXY-PICOLINIC ACID** v. **CHLORO-OXY-PYRIDINE CARBOXYLIC ACID**.

**CHLORO-OXY-PROPANE SULFONIC ACID**  $C_3H_4ClSO_3$ , i.e.  $CH_2Cl.CH(OH).CH_2SO_3H$ . From epichlorhydrin and  $Na_2SO_3$  at 100° (Darmstädter, A. 148, 126). Syrup.— $NaA'$  2aq: monoclinic crystals.— $NaA'$  aq: trimetric tables.— $NaA'$  1aq (Pazschke, J. pr. [2] 1, 94).— $CaA'$  6aq.— $BaA'$  2aq.  $PbA'$  2aq.— $AgA'$  3aq.

### 3-CHLORO- $\alpha$ -OXY-PROPIONIC ACID

**$CH_2Cl.CH(OH).CO_2H$** . *Chloro-lactic acid*. [78°]. *Formation*.—1. From chloro-acetic aldehyde by treatment with  $HCl$  and  $HCl$  (Glinzky, Z. 1870, 516; Frank, A. 206, 344).—2. Together with its isomeride by the union of  $HOCl$  with acrylic acid in aqueous solution at 0° (Melikoff, B. 13, 2153).

*Preparation*.—Epichlorhydrin (5 g.) is heated with (20 g. of) nitric acid (S.G. 1.38) on a water bath until the odour of chloropierin is perceived. The product is poured into water and extracted with ether. On evaporation this leaves an oil that solidifies over  $H_2SO_4$  (v. Richter, J. pr. 128, 193).

*Properties*.—Flat, deliquescent prisms. V. sol. water, alcohol, and ether. Cannot be distilled. Moist  $Ag_2O$  converts it into glyceric acid. When heated with water it splits up into aldehyde,  $CO_2$ , and  $HCl$  (Erlenmeyer, B. 13, 309).

*Salts*.— $CaA'$  3aq.— $ZnA'$  3aq.— $MnA'$  3aq.  $CuA'_2$ — $AgA'$ .

*Methyl ether*  $MeA'$ : (186°); liquid.

*Ethyl ether*  $EtA'$ : [37°]. (205°).

$\alpha$ -Chloro- $\beta$ -oxy-propionic acid

**$CH_2OH.CHCl.CO_2H$** .

*Formation*.—1. From glyceric acid and  $HCl$  (Werigo a. Melikoff, B. 12, 178).—2. From acrylic acid and  $HOCl$ .—3. By the action of water on  $\alpha$ -di-chloro-propionic acid (Melikoff, B. 12, 2227).—4. From oxy-acrylic acid and  $HCl$  (Melikoff, B. 13, 278).

*Properties*.—Syrup. V. sol. water, alcohol, and ether. Converted by moist  $Ag_2O$  into glyceric acid, and by alcoholic  $KOH$  into oxy-acrylic acid. Conc.  $HCl$  forms, at 100°,  $\alpha$ , $\beta$ -di-chloro-propionic acid [50°]. Zinc and dilute  $H_2SO_4$  reduce it to hydroacrylic acid (Melikoff, J. R. 13, 164).

*Salt*.— $ZnA'_2$ : hygroscopic gummy mass.

*Di-chloro-oxy-propionic acid*

**$CHCl_2.CH(OH).CO_2H$** . [77°]. From di-chloro-acetic aldehyde,  $HCl$ , and  $HCl$  (Grimaux a. Adam, B. 10, 903; Bl. [2] 34, 29). Deliquescent tables; v. e. sol. water, alcohol, and ether. Reduces ammoniacal  $AgNO_3$ .

*Ethyl ether*  $EtA'$ : (220°). From the acid. Also from tri-chloro-oxy-propionic ether in alcoholic solution, by treatment with zinc, and  $HCl$  (Pinner a. Bischoff, A. 179, 88).

*Tri-chloro-oxy-propionic acid*  
 **$CCl_3.CH(OH).CO_2H$** . *Tri-chloro-lactic acid*. [105°–110°]. From its nitrile by  $HCl$  (Pinner, A. 179, 79; B. 17, 1997). Prisms; sol. ether. Split up by alkalis into chloral and formic acid.

*Reactions*.—1. With strong aqueous  $NH_3$  it gives glycossine.—2. With hydroxylamine it yields glyoxim.—3. With phenyl-hydrazine it yields glyoxal-di-phenyl-hydrazide.—4. With urea and a little water it gives acetylene-urea

$C_2H_4N_2O$ , i.e.  $OC \begin{matrix} \diagup NH.CH.NH \\ \diagdown NH.CH.NH \end{matrix} CO$  (Pinner, B.

17, 1997).—5. Fusion with urea forms some uric acid (Horbaczewski, M. 8, 584).

*Salts*.— $NH_4A'$ — $KA'$ : prisms.

*Ethyl ether*  $EtA'$ : [67°]. (c. 235°). Formed by heating chloralide with alcohol (Wallach, A. 133, 8).

*Preparation*.—Chloral-hydrate is converted into its cyanhydrin by mixing with strong  $HCl$ , and after 24 hrs. standing the mixture is digested on the water-bath for 4–6 hrs. and evaporated. The crystalline cyanhydrin is dissolved in one-third its weight of alcohol and  $HCl$  gas led into the boiling solution. When the reaction is complete the ether is precipitated by water, and solidifies on cooling; the yield is 90 p.c. of the theoretical (Pinner, B. 18, 754).

*Properties*.—Insol. water. Converted by alkalis into tartaric acid. Zinc and  $HCl$  reduce it, in alcoholic solution, to di-chloro-oxy-propionic acid.

*Acetyl derivative*  $CCl_3.CH(OAc).CO_2H$ . [65°].

*Tri-chloro-ethylidene ether* v. **CHLORALDEHYDE**.

*Tri-bromo-ethylidene ether*

**$CBr_3.CH \begin{matrix} \diagup O.CO \\ \diagdown O.CO \end{matrix} CH.CCl_3$** . [149°] (Wallach, A. 193, 1).

*Amide*  $CCl_3.CH(OH).CONH_2$ . [96°]. From the nitrile,  $HOAc$ , and  $H_2SO_4$  (Pinner a. Fuchs, B. 10, 1061). Slender needles; v. sol. cold water. *Acetyl derivative*  $CCl_3.CH(OAc).CO.NH_2$ . [95°].

*Nitrile*  $CCl_3.CH(OH).CN$ . [61°]. (c. 218°). From chloral and  $HCl$  (Hagemann, B. 5, 151; Pinner a. Bischoff, A. 179, 77; 17, 1997). Trimetric tables (from  $CS_2$ ). V. sol. water, alcohol, and ether. *Reactions*.—1. Alkalis split it up into chloroform,  $HCO_2$ , and formic acid.—2. Ammonia forms di-chloro-acetamide.—3. Heated with urea it yields tri-chloro-ethylidene-di-ureide  $CCl_3.CH(NH.CO.NH_2)_2$ , as chief product, and biuret as a by-product (Pinner a. Litschütz, B. 20, 2345).

*Acetyl derivative*  $CCl_3.C(OAc).CN$ . [31°]. (208°).

**TRI-CHLORO- $\beta$ -OXY-(A.)-PROPYL-ACRIDINE**  $C_{14}H_9ONCl_3$

*Methyl-acridine chloral*. Formed by warming (A.)-methyl-acridine (60 g.) suspended in benzene (600 g.) with anhydrous chloral (70 g.); at 70°–75° the product separates as a sandy pp.; the yield is nearly theoretical. Yellow needles or prisms. Above 200° it is again resolved into

# TRI-CHLORO-OXY-PROPYL-ACRIDINE,

methyl-acridine and chloral. SL. sol. all ordinary solvents. Its basic properties are very slight. The solution in conc.  $H_2SO_4$  has a splendid greenish-yellow fluorescence. By alkalis it is partially resolved into methyl-acridine and chloral, and partly converted into acridyl-acrylic acid  $C_{12}H_9N.CH:CH.CO_2H$  whence  $KMnO_4$  produces

(Bernthsen & Muhlert, B. 20, 1542).

**DI-CHLORO-OXY-PYRIDINE**  $C_5H_4(OH)Cl_2N$  [178°]. Formed by heating the ethyl ether with  $HCl$  (Koenigs & Geigy, B. 17, 1834). Colourless crystals. V. sol. hot water.

**Ethyl-ether**  $C_5H_4(OEt)Cl_2N$ : [81°]; white crystals; formed by heating tri-chloro-pyridine with sodium ethylate.

**CHLORO-(γ)-OXY-PYRIDINE CARBOXYLIC ACID**  $C_5H_4ClN(OH)(CO_2H)$ . *Chloro-oxy-picolinic acid*. S. 4 at 100°.

**Preparation.**—Comenamic acid (q.v.) is heated with  $PCl_5$  (5 equivalents) in a sealed tube at 220°. The product is poured into water at 0°. The oil that separates is extracted with hot water and the extract evaporated to crystallisation. The crystals are dissolved in a little hot water and  $NH_3$  is added: ammoniac comenamate separates and calcic chloride is then added to the filtrate. Calcic chloro-oxy-methyl pyridine carboxylate crystallises out slowly (Bellmann, J. pr. [2] 29, 3).

**Properties.**—Pointed needles (containing aq.). Insol. cold water, ether, chloroform, and benzene. Sol. alcohol and acids.

**Reactions.**—1.  $FeCl_3$  gives a brown pp. sol. excess.—2.  $AgNO_3$  gives a bulky white pp. soon becoming granular.—3. Reduced by  $Sn$  and  $HCl$  to (γ)-oxy-pyridine carboxylic acid ((γ)-oxy-picolinic acid).

**Salts.**— $B^+HCl$ . Very soluble pointed needles.  $CaA'$ , aq. Got by adding  $CaCl_2$  to a solution of the acid nearly neutralised by  $NH_3$ . M. sol. water.— $C_5H_4ClN \begin{array}{c} \diagup O \\ | \\ CO_2 \end{array} Ca \frac{1}{2} aq.$  Got by adding  $CaCl_2$  to a solution of the acid quite neutralised by  $KH$ .

**Chloro-oxy-pyridine carboxylic acid**  $C_5H_4ClN(OH)CO_2H$ . *Chloro-oxy-picolinic acid*. [e. 257°]. Obtained by heating penta-chloro-methyl-pyridine  $C_5H_4Cl_5N.COCl$  with  $H_2SO_4$  (Ost, J. pr. [2] 27, 257). Thick needles (containing aq.). Reduced by  $HI$  in acetic acid to (β)-oxy-picolinic acid.

**Salt.**— $CaA'$ , 4a.

**Chloro-oxy-pyridine carboxylic acid**  $C_5H_4ClN(OH)CO_2H$ . *Chloro-oxy-picolinic acid*. Obtained by the action of  $H_2SO_4$  on penta-chloro-methyl-pyridine obtained by treating picolinic acid with  $PCl_5$  (Seyferth, J. pr. [2] 84, 244). Clusters of needles. Does not melt below 315°. SL. sol. cold water. Does not combine with  $HCl$ .

**Chloro-oxy-pyridine carboxylic acid**  $C_5H_4ClN(OH)CO_2H$ . *Chloro-oxy-nicotinic acid*. [502°]. From nicotinic acid by successive treatment with  $PCl_5$  and  $H_2SO_4$ . Monoclinic prisms (B.).

**Di-chloro-oxy-pyridine carboxylic acid**  $C_5H_4Cl_2N(OH)CO_2H$ . *Di-chloro-oxy-picolinic acid*. [e. 252°].

**Preparation.**—By heating hexa-chloro-me-

thyl-pyridine  $C_5H_4Cl_6N.COCl$  with (80 p.p.)  $H_2SO_4$  (Ost, J. pr. [2] 27, 257).

**Properties.**—Felt-work of fine needles (containing aq.) (from water), or else as small hard prisms. Decomposes about 282°. Not attacked by  $Sn$  and  $HCl$  or by aqueous  $HI$ . Reduced by  $HI$  in glacial acetic acid to (α)-oxy-picolinic acid.

**Salts.**—Mostly soluble, except the calcium salt,  $CaA'$ , which is but slightly soluble, although it is more soluble than the acid. Separates by spontaneous evaporation as silvery stars.

**CHLORO-OXY-PYROTARTARIC ACID**  $C_4H_4ClO_6$ . *Chloro-citraconic acid*. [100°].

**Formation.**—1. From citraconates and  $HCl$  (Oarius, A. 126, 204).—2. From citra- or meso-di-chloro-pyrotartaric acid by warming with water (Gottlieb, A. 160, 104; Morawski, J. pr. [2] 10, 68; 11, 466).—3. By passing chlorine into an aqueous solution of sodium mesaconate (Morawski, J. pr. [2] 12, 899).

**Properties.**—Trimetric crystals. Water at 120° converts it into di-oxy-pyrotartaric acid and acetone.

**Salts.**— $BaA'$  4aq: monoclinic tables, v. al. sol. cold water.— $PbA'$  4aq.— $Ag_2A'$ .

**Chloro-oxy-pyrotartaric acid**  $C_4H_4ClO_6$ . *Hydro-chloro-oxy-citraconic acid*. [162°]. From oxy-citraconic acid and fuming  $HCl$  at 120° (Morawski, J. pr. [2] 11, 448). Plates. Split up by bases into  $HCl$  and oxy-citraconic acid. Sodium amalgam reduces it to oxy-pyrotartaric acid q.v.

**CHLORO-OXY-QUINOLINE**  $C_8H_6NCl$  *etc.*

of bleaching powder solution on the borate of quinoline (Einhorn & Lauch, A. 243, 843). White prismatic needles. Sol. hot water, acetic ether,  $HOAc$ .

**Reactions.**—1. Boiled in an alkaline solution carbostyryl is formed.—2.  $PCl_5$  forms (Py. 3) chloro-quinoline.—3. Boiled with alcohol p-chloro-carbostyryl [268°] is formed.

(B. 2.) Chloro-(Py. 3)-oxy-quinoline

*p-Chloro-carbostyryl*. [268°].

Formed by treating the following body with alkalis, and, by intramolecular change, from the preceding body. When its alkaline solution mixed with  $NaOCl$  is treated with  $CO$ , the following body is ppd.  $KMnO_4$  gives *p-chloro-tetralin* [248°].

(B. 2, Py. 3.) Di-chloro-(Py. 3)-oxy-quinoline

[115°] and [145°]. From

(B. 2.) chloro-quinoline and bleaching powder (Einhorn & Lauch, A. 243, 859). Plates (from  $HOAc$ ) or needles (from  $Et(OAc)$ ). Dimorphic. Boiling alkalis give chloro-carbostyryl [268°].

Chloro-oxy-quinoline v. **CHLORO-CARBOSTYRYL**.

**Tri-chloro-oxy-quinoline**  $C_8H_4Cl_3ON$ . [200°].

Prepared by passing chlorine for 6 hours into a solution of quinoline in dilute acetic acid. The product is crystallised from alcohol. The yield is 15 p.p., most of the quinoline being recovered. Thin matted needles, sol. benzene, chloroform, and alcohol. Reduced by  $HI$  at 260° to oxy-quinoline, which is found to be (Py. 3)-oxy-quinoline (J. Rothelt, J. pr. [2] 29, 300).

**(Py. 2:4)-CHLORO-OXY-ISOQUINOLINE**

$C_6H_4ClNO$  &  $C_6H_4$   $\begin{matrix} CH=CCl \\ | \\ C(OH):N \end{matrix}$  or  $C_6H_4$   $\begin{matrix} CH=CCl \\ | \\ CO.NH \end{matrix}$  [220°]. Fine needles. V. sol. ordinary solvents. Dissolve in dilute NaOH. Formed as a by-product in the action of alcoholic KOH upon di-chloro-isoquinoline. Obtained by the action of dry HCl gas at c. 150° upon (Py. 2:4)-chloro-

methoxy-isoquinoline  $C_6H_4$   $\begin{matrix} CH=CCl \\ | \\ C(OMe):N \end{matrix}$ . On

methylation with MeI and methyl alcoholic KOH, it is converted into (Py. 2:4:3)-chloro-oxy-methoxy-isoquinoline  $C_6H_4$   $\begin{matrix} CH=CCl \\ | \\ CO.NMe \end{matrix}$ , isomeric with

the above chloro-methoxy-isoquinoline (Gabriel, B. 19, 2360).

**Methyl derivative**  $C_6H_4$   $\begin{matrix} CH=CCl \\ | \\ C(OMe):N \end{matrix}$

[74°]. Formed by heating di-chloro-isoquinoline with a solution of sodium in methyl alcohol, at 100°. Thick needles. V. sol. alcohol, ether, &c. By digestion with fuming HCl at 100° it is converted into the imide of phenyl-acetic-o-carboxylic acid  $C_6H_4$   $\begin{matrix} CH_2.CO \\ | \\ CO.NH \end{matrix}$  (di-oxy-isoquinoline). By

dry HCl at 150° it is converted into chloro-oxy-isoquinoline (Gabriel, B. 19, 2359).

**Ethyl derivative**  $C_6H_4$   $\begin{matrix} CH=CCl \\ | \\ C(OEt):N \end{matrix}$

[37°]. Formed by heating di-chloro-isoquinoline with alcoholic sodium ethylate at 100°. Long needles. V. sol. ordinary solvents (Gabriel, B. 19, 2358).

(Py. 4:2)-Chloro-oxy-isoquinoline  $C_6H_4ClNO$  &  $C_6H_4$   $\begin{matrix} OH:C(OH) \\ | \\ CCl:N \end{matrix}$  or  $C_6H_4$   $\begin{matrix} CH_2.CO \\ | \\ CCl:N \end{matrix}$  [197°].

Formed as a by-product in the preparation of di-chloro-isoquinoline by the action of POCl<sub>3</sub> at 150°-170° upon the imide of phenyl-acetic-o-carboxylic acid  $C_6H_4$   $\begin{matrix} CH_2.CO \\ | \\ CO.NH \end{matrix}$  (di-oxy-isoquinoline). Long thick needles, or colourless plates.

M. sol. hot alcohol, sl. sol. ether, cold acetic acid, hot benzene, and chloroform.

**Methyl derivative**  $C_6H_4(CH_3)NO$  : [87°]. Small white crystals; v. sol. alcohol, ether, &c., insol. alkalis. Formed by heating chloro-oxy-isoquinoline with MeI and methyl-alcoholic KOH (Gabriel, B. 19, 2356).

Di-chloro-oxy-isoquinoline (?)

$C_6H_4Cl_2NO$  probably  $C_6H_4$   $\begin{matrix} CO.CHCl \\ | \\ CCl:N \end{matrix}$ . Formed by heating hippuric acid with POCl<sub>3</sub>. By further action of POCl<sub>3</sub> it is converted into a body  $C_6H_4Cl_2N$ , [184°] (Rügheimer, B. 19, 1189; cf. Schwabert, A. 113, 59).

**Di-p-CHLORO-DI-OXY-QUINONE**  $C_6Cl_4(OH)_2O$  [1:4:2:5:3:6]. **Chloranilic acid** (Hantzsch, B. 20, 2808, 2279).

**Formation**.—1. By dissolving tetra-chloro-quinone (chloranil) in dilute aqueous KOH (Brdmann, J. pr. 32, 381; cf. Stenhouse, A.

Suppl. 8, 14).—2. By the action of potash on tri-chloro-quinone (Graebe, A. 146, 24).

**Properties**.—Glittering red plates (containing aq). May be partially sublimed. Its aqueous solution is violet, but decolourised by HCl or H<sub>2</sub>SO<sub>4</sub>, by which it is ppd.

**Reactions**.—1. Reduced by tin and HCl to di-chloro-tetra-oxy-benzene.—2. PCl<sub>5</sub> forms tetra-chloro-quinone.—3. By treatment with bromine it is converted into di-chloro-tetra-bromo-acetone CBr<sub>2</sub>Cl.CO.CBr<sub>2</sub>Cl [79°] (Levy a. Jedlička, B. 20, 2318; cf. Stenhouse, A. Suppl. 8, 17).—4. HCl and KClO<sub>4</sub> form tetra-chloro-acetone CHCl<sub>2</sub>.CO.CHCl<sub>2</sub>, which crystallises with 4aq [49°] (Levy a. Jedlička, B. 21, 318).—5. Ammonia forms C<sub>6</sub>Cl<sub>4</sub>O<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub>(OH)<sub>2</sub> 3aq crystallising in black needles and forming the salts C<sub>6</sub>Cl<sub>4</sub>O<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub>(ONH<sub>2</sub>) 4aq and C<sub>6</sub>Cl<sub>4</sub>O<sub>2</sub>(NH<sub>2</sub>)<sub>2</sub>(OAg). 6. A small quantity of SO<sub>2</sub> forms tetra-chloro-tetra-oxy-quinhydrone C<sub>2</sub>H<sub>2</sub>Cl<sub>4</sub>O<sub>4</sub>, crystallising in black needles.

**Salts**.—K<sub>2</sub>C<sub>6</sub>Cl<sub>4</sub>O<sub>4</sub> aq: purple prisms, forming a purple solution in water or alcohol.—Na<sub>2</sub>A'' 4aq: dark crimson needles (Hesse, A. 114, 304).—BaA'' 3aq: red-brown scales.—AgA'' red pp.

**Di-ethyl ether** Et<sub>2</sub>C<sub>6</sub>Cl<sub>4</sub>O<sub>4</sub>. Red prisms (from alcohol).

**CHLORO-DI-OXY-QUINONE SULPHONIC ACID** C<sub>6</sub>H<sub>2</sub>ClSO<sub>3</sub>, i.e. C<sub>6</sub>Cl(OH)<sub>2</sub>O<sub>2</sub>(SO<sub>3</sub>H). Potassium salt C<sub>6</sub>Cl(OK)<sub>2</sub>O<sub>2</sub>(SO<sub>3</sub>K) 2aq. From tri-chloro-hydroquinone sulphonic acid and KOH (Graebe, A. 146, 55). Red needles; v. sol. water, insol. alcohol. With HCl it gives yellow laminar C<sub>6</sub>Cl(OH)<sub>2</sub>O<sub>2</sub>(SO<sub>3</sub>K), decolourised by tin and HCl.

**Di-p-CHLORO-DI-OXY-TEREPHTHALIC ACID** C<sub>6</sub>Cl<sub>2</sub>(OH)<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub> [1:4:2:5:3:6]. From the colourless ether (v. infra) and conc. aqueous NaOH at 100°. Greenish-yellow needles (containing 2aq). Stable in the air, but effloresces over H<sub>2</sub>SO<sub>4</sub> into the white anhydrous pseudo-form (di-chloro-quinone di-hydro-di-carboxylic acid) which is reconverted into the unstable form by heating with aqueous NaOH.

**Ethyl ether**. **Di-chloro-hydroquinone-di-carboxylic ether**. [123°]. Formed by reduction of di-chloro-quinone-di-carboxylic ether C<sub>6</sub>Cl<sub>2</sub>O<sub>2</sub>(CO<sub>2</sub>Et)<sub>2</sub> with zinc-dust and acetic acid. Long thin colourless needles. V. sol. ether. By melting and quick cooling it is converted into yellowish-green dichroic tables, which are probably the pseudo-form C<sub>6</sub>H<sub>2</sub>Cl<sub>2</sub>O<sub>2</sub>(CO<sub>2</sub>Et)<sub>2</sub> (di-chloro-quinone-di-hydro-di-carboxylic ether); this is unstable, and by a gentle warming is converted back into the colourless needles of the stable form (Hantzsch a. Zeckendorf, B. 20, 1812).

**CHLORO-OXY-THYMOQUINONE** C<sub>9</sub>H<sub>4</sub>(OH)ClO<sub>2</sub>, i.e. C<sub>6</sub>Cl(CH<sub>3</sub>)(C<sub>3</sub>H<sub>3</sub>)O<sub>2</sub>(OH) [123°]. From di-nitrothymol by treatment with POCl<sub>3</sub>, the chloro-di-nitro-thymol so formed being reduced by tin and HCl and the resulting amido-compound oxidised by CrO<sub>3</sub> (Ladenburg a. Engelbrecht, B. 10, 1218). Lemon-yellow prisms (from Alcohol). Readily sublimes. Its alkaline solutions are violet. Boiling with KOH converts it into di-oxy-thymoquinone.

**CHLORO-OXY-TOLUARBOSTYRIL**

**CHLORO-DI-OXY-METHYL-QUINOLINE**

# CHLORO-OXY-TOLUQUINOLINE

**CHLORO-OXY-TOLUQUINOLINE** v. **CHLORO-XY-QUINOLINE**.

**DI-CHLORO-DI-OXY-TOLUQUINONE** (?).  $C_8H_5Cl_2O_2$ , i.e.  $C_6Cl_2Me(OH)O_2$ . [157°]. From tri-chloro-orein and alkaline  $K_2FeO_4$  (Stenhouse a. Groves, B. 18, 1806). Deep yellow scales (from water). Sl. sol. water, v. sol. alcohol. Reduced by  $SO_2$  to colourless  $C_8H_5Cl_2O_2$ , which on oxidation gives purplish-brown crystals of a quinhydrone. A di-chloro-di-oxy-toluquinone has been described by Bräuninger (A. 185, 339) as obtained from beech-wood creosote by treatment with  $KClO_4$  and  $HCl$ ; the resulting tetra-chloro-toluquinone being reduced by  $SO_2$  to the tetra-chloro-hydrotoluquinone, whence dilute  $KOH$  forms di-chloro-di-oxy-toluquinone, a brick-red crystalline powder.

**DI-CHLORO-DI-OXY-DI-o-TOLYL-PYRAZINE**  $C_8H_5N_2 - CCl_2CO$ .

**ZINE**  $CO.CCl_2N_2C_6H_5$ . [201°]. From di-oxy-di-tolyl-pyrazine dihydride and  $PCl_5$  (Abenius a. Widmann, B. 21, 1662).

**CHLORO-OXY-VALERIC ACID**  $C_5H_7Cl(OH).CH_2.CO_2H$ . Obtained by oxidising chloro-allyl-propyl alcohol by chromic mixture (Lopatin, J. pr. [2] 30, 386). Crystalline. Salts.— $BaA'$ ,  $Saq$ .— $NaA'$ ,  $aq$ .

**γ-Chloro-γ-oxy-valeric acid**  
**Lactone**  $C_5H_7O_2Cl$  i.e.  $CH_2.CCl.CH_2.CH_2.CO.O$  (80°-83°) at 10 mm. Got by passing  $HCl$  into (α)-angelico-lactone. Decomposed by water into  $HCl$  and levulic acid. On distillation it splits up into  $HCl$  and (β)-angelico-lactone. Bromine converts the lactone into brominated bodies, whence water forms a great deal of di-bromo-levulic acid and some bromo-levulic acid (Wolff, A. 229, 249).

**Chloro-oxy-valeric acid**  $C_5H_7ClO_2$ , i.e.  $CH_2.CHCl.CMe(OH).CO_2H$ . [75°]. Formed, together with its isomeride, by the union of tiglic acid with  $HOCl$  (Melikoff, A. 234, 225; B. [2] 47, 166). Needles, sol. water, alcohol, and ether. Alcoholic  $KOH$  converts it into butylenic oxide carboxylic (di-methyl-glycidic) acid

$O$   
 $CH_2.CH.CMe.CO_2H$  [62°], whence  $HCl$  reproduces the original acid [75°].

**Salts**.— $ZnA'$ ,  $CaA'$ : prisms.  
**Chloro-oxy-valeric acid**  $CH_2.CH(OH).CMeCl.CO_2H$ . [112°]. Formed, together with the preceding, by the union of  $HOCl$  with tiglic acid (M.). Prisms; v. sol. water, alcohol, and ether. Alcoholic  $KOH$  converts it into the same butylene oxide carboxylic acid as the preceding.

**Salts**.—These are gummy masses.— $ZnA'$ ,  $CaA'$ ,  $BaA'$ .

**Tri-chloro-oxy-valeric acid**  $CH_2.CHCl.CCl.CH(OH).CO_2H$ . [140°]. Prepared by boiling with  $HCl$  the compound of tri-chloro-butyric aldehyde with  $HCN$  (Pinner a. Klein, B. 11, 1492; A. 179, 99). Trimetric tables, v. sol. alcohol, ether, and hot water.

**Salts**.— $NaA'$ ,  $aq$ : crystals.— $PbA'$ : amorphous pp.

**Ethyl ether**  $EtA'$ . [40°]. (255°). Long prisms. Alcoholic  $NH_3$  converts it into  $C_5H_7ClN_2O$

(? amide of chloro-imido-angelic acid) [116°] whence boiling alcohol produces  $C_5H_7ClNO$ .

**Acetyl derivative**  $C_5H_7AcClO_2$ ,  $aq$ . [84°]. Slender needles.

**Tri-chloro-ethylidene ether**  
 $CCl_2CH \begin{smallmatrix} O \\ \diagup \diagdown \\ O \end{smallmatrix} CCl_2CH \begin{smallmatrix} O \\ \diagup \diagdown \\ O \end{smallmatrix} CCl_2CH$ . [87°].

(297°). From the acid and chloral at 175° (Wallach, A. 193, 87). Thick crystals (from chloroform); explodes when struck.

**Amide**  $CH_2.CHCl.CCl_2.CH(OH).CO.NH_2$ . [119°]. Sl. sol. water and  $C_2H_5$ , v. sol. alcohol and ether. Prepared by the action of strong  $H_2SO_4$  on the nitrile (Pinner a. Klein, B. 11, 1490).

**Nitrile**  $CH_2.CHCl.CCl_2.CH(OH).CN$ . **Butyl-chloral cyanhydrin**. [102°]. (q. 230°). From tri-chloro-butyric orthoaldehyde, alcohol, and conc.  $HCl$ . Leaflets (from dilute  $HCl$ ); m. sol. cold water, v. sol. alcohol. Converted by alcoholic  $NH_3$  into the amide of (β)-chloro-ortho-tonic acid. Urea gives chloro-ortho-tonic uret  $C_5H_7Cl.CONH.CO.NH_2$  and butyro-chloral biuret.

**Acetyl derivative of the nitrile**  $CH_2.CHCl.CCl_2.CH(OAc).CN$ . (240°-252°). From the nitrile and  $AcCl$ . Yellowish oil.

**TETRA-CHLORO-o-DI-OXY-XYLENE**. **Anhydride**  $C_6H_2Cl_4O$  i.e.  $C_6Cl_4 \begin{smallmatrix} CH_2 \\ \diagup \diagdown \\ O \end{smallmatrix}$ . [218°]. From tetra-chloro-phthalic acid (7.7 g.), conc.  $HI$  (8.5 c.c.) and red phosphorus (2 g.) at 230° (Graebe, A. 238, 831). Needles (from toluene). Sl. sol. hot alcohol, m. sol. hot benzene or  $HOAc$ . Insol. boiling alkalis.

**CHLORO-PENTANE** v. **AMYL CHLORIDE**.  
**Di-chloro-pentane**  $C_5H_{10}Cl_2$ . **Amylene chloride**. (145°). S.G. 1.22;  $n_D^{20}$  1.058. From crude amylene and  $PCl_5$  (Guthrie, C. J. 14, 128; A. 121, 115) or  $Cl_2$ , the temperature being first at -15°, afterwards boiling (Bauer, Z. [2] 4, 880, 667; cf. Kondakoff, C. C. 1887, 959).

**Di-chloro-pentane**  $(CH_3)_2CH.CH_2.CHCl_2$ . **Isoamylene chloride**. (130°). S.G. 1.05. From isovaleric aldehyde and  $PCl_5$  (Ebersbach, A. 106, 265).  $KOH$  gives  $(CH_3)_2CH.CH_2.CHCl_2$  (86°) and  $(CH_3)_2CH.C_2H_5$  (Brylants, B. 8, 418).  
**α-Di-chloro-pentane**  $CH_3.CH_2.CH_2.CCl_2.CH_3$ . From methyl propyl ketone and  $PCl_5$  (Brylants, B. 8, 411). Liquid; decomposed by distillation. Dry  $KOH$  forms  $CH_3.CH_2.CH_2.C_2H_5$ . Alcoholic  $KOH$  forms  $CH_3.CH_2.CH_2.CCl_2.CH_3$  (96°) and  $CH_3.C_2H_5.C_2H_5$  (Favorsky, B. [2] 45, 247).

**Di-chloro-pentane**  $C_5H_{10}Cl_2$ . (155°-160°). S.G. 1.19. Formed by chlorination of ordinary amyl chloride (Buff, A. 148, 850).

**Di-chloro-pentane**  $C_5H_{10}Cl_2$ . (151°). From valerylene and  $HCl$  at 100° (Reboul, Z. 1887, 179). Heavy oil.

**Tri-chloro-pentane**  $C_5H_9Cl_3$ . (165°-190°). S.G. 1.33. By chlorination of ordinary amyl chloride (Buff, A. 148, 850). A crystalline tri-chloro-pentane is formed (160°-180°) by chlorinating crude amylene (Bauer, J. pr. 100, 42).

**Tetra-chloro-pentane**  $C_5H_8Cl_4$ . (240°). S.G. 1.429. From amylene and  $Cl_2$  (Bauer, J. pr. 100, 43).

**Penta- and Hexa-chloro-pentanes** have been obtained by Spring a. Leorenor (B. [2] 48, 628) by chlorinating isoamyl mercaptan.

**CHLORO-ISO-PENTANE SULPHONIC ACID**  $C_5H_9ClSO_3H$ . From isopentane sulphonic acid

and Cl in sunshine or, in presence of iodine, at 180° (Spring a. Winsinger, *B.* 17, 537; *B.* [2] 41, 801).—BaA'.

**CHLORO-PENTENOIC ACID** v. **CHLORO-ANGELIC ACID** and **CHLORO-TRIGLIC ACID**.

#### CHLORO-PENTENYL ALCOHOL

**CH<sub>2</sub>.CH.CCl.OHMe.OH.** *Methyl-chloro-allyl carbinol.* (159°) at 725 mm. S.G.  $\frac{141}{171}$  1.0882. V.D. 4.09 (Theory 4.17). From tri-chloro-amylic alcohol C<sub>2</sub>H<sub>4</sub>Cl<sub>3</sub>.CHMe.OH, finely divided iron, and acetic acid (Garzarolli-Thuralackh, *A.* 223, 154), or zinc-dust and dilute HCl. Colourless mobile liquid with pungent smell, faintly soluble in water, soluble in ether, CS<sub>2</sub>, and chloroform. Combines with bromine. Acetic acid is among the products of oxidation by chromic mixture.

*Acetyl derivative* C<sub>2</sub>H<sub>4</sub>AsClO. (173°) at 735 mm. V.D. 5.73 (theor 5.66). Does not combine with bromine.

• **PER-CHLORO-PENTINENE** C<sub>5</sub>Cl<sub>10</sub>. *Per-chloro-mecylene.* [189°]. From cemenic acid and PCl<sub>5</sub> at 280° (Offt, *J. pr.* [2] 27, 293). Prisms (from alcohol); smells like camphor. Begins to distil with decomposition at 270°.

**CHLORO-PHENANTHRENE** v. **PHENANTHRENE**.

**CHLORO-PHENETOL** v. *Ethyl ether of CHLORO-PHENOL.*

*o*-**CHLORO-PHENOL** C<sub>6</sub>H<sub>4</sub>Cl(OH) [2:1]. [7°]. (176° i.V.).

*Formation*.—1. From *o*-amido-phenol by displacing NH<sub>2</sub> by Cl by the diazo-reaction (Schmitt a. Cook, *B.* 1, 67; Faust a. Müller, *B.* 5, 777). Solution of NaNO<sub>2</sub> is run into a hot solution of *o*-amido-phenol and Cu<sub>2</sub>Cl<sub>2</sub> in dilute HCl (Sandmeyer, *B.* 17, 2651).—2. Together with the *p*-isomeride by passing chlorine into phenol (F. a. M.; Krämers, *A.* 173, 331).—3. From *o*-chloro-aniline by displacing NH<sub>2</sub> by OH through the diazo-reaction (Beilstein a. Kurbatoff, *A.* 146, 39).—4. Formed by neutralising with acid a mixture of sodium hypochlorite and phenol (Chandelon, *B.* 16, 1749).

*Properties*.—Colourless liquid; sl. sol. water, v. sol. alcohol and ether. Potash-fusion converts it into pyrocatechin (Petersen, *B.* 6, 368). HNO<sub>3</sub> gives two chloro-nitro-phenols [111°] and [70°]. PCl<sub>5</sub> gives *o*-di-chloro-benzene (179°).

*Methyl ether* C<sub>6</sub>H<sub>4</sub>Cl(OMe). *o*-**Chloro-anisol.** (203°). Prepared from *o*-anisidine C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)(OMe) by Sandmeyer's reaction (Wallach a. Hensler, *A.* 243, 237; cf. Fischli, *B.* 11, 1468).

*Ethyl ether* C<sub>6</sub>H<sub>4</sub>Cl(OEt). *o*-**Chloro-phenetol.** (208°).

*Benzoyl derivative* C<sub>6</sub>H<sub>4</sub>Cl.OBz. [814°].

*Phthalyl derivative* C<sub>6</sub>H<sub>4</sub>Cl.O<sub>2</sub>(CO.C<sub>6</sub>H<sub>4</sub>Cl). [98°] (Mosso, *C. C.* 1887, 1396).

*m*-**Chloro-phenol** C<sub>6</sub>H<sub>4</sub>Cl(OH) [3:1]. [28.5°]. (214° i.V.). From *m*-chloro-aniline by displacing NH<sub>2</sub> by OH through the diazo-reaction (Beilstein a. Kurbatoff, *A.* 176, 45; Uhlemann, *B.* 11, 1161; Varnholt, *J. pr.* [2] 36, 26). White needles.

*Benzoyl derivative* C<sub>6</sub>H<sub>4</sub>Cl(OBz). [86°].

*Phthalyl derivative* [108°] (Mosso).

*p*-**Chloro-phenol** C<sub>6</sub>H<sub>4</sub>Cl(OH) [4:1]. [37°]. (217°).

*Formation*.—1. From phenol and SO<sub>2</sub>Cl<sub>2</sub> (Dubois, *Z.* [2] 2, 705; 3, 305).—2. Together with the *o*-isomeride by passing chlorine into

cold phenol (D.; Petersen a. Bähr-Praderi, *A.* 157, 123).—3. From *p*-amido-phenol by displacing NH<sub>2</sub> by Cl through the diazo-reaction (Schmitt, *B.* 1, 87).—4. From *p*-chloro-aniline by displacing NH<sub>2</sub> by OH through the diazo-reaction (Beilstein a. Kurbatoff, *A.* 176, 30; *B.* 7, 1395).

*Properties*.—Crystalline; v. sl. sol. water, v. s. sol. alcohol and ether. Insol. aqueous Na<sub>2</sub>CO<sub>3</sub>. Potash-fusion converts it into hydroquinone and resorcin (Petersen, *B.* 6, 1399; 7, 61; cf. Faust, *B.* 6, 1022). PCl<sub>5</sub> gives *p*-di-chloro-benzene [53°]. HNO<sub>3</sub> forms chloro-nitro-phenol [87°].

*Salt*.—C<sub>6</sub>H<sub>4</sub>Cl(O<sup>+</sup>Na) (Varnholt, *J. pr.* [2] 86, 19).

*Methyl ether* C<sub>6</sub>H<sub>4</sub>Cl(OMe). (a. 200°); S.G. 1.182 (Henry, *Z.* [2] 6, 247).

*Ethyl ether* C<sub>6</sub>H<sub>4</sub>Cl(OEt). [21°]. (211°).

*Benzoyl derivative* C<sub>6</sub>H<sub>4</sub>Cl(OBz). [93°].

*Phthalyl derivative* C<sub>6</sub>H<sub>4</sub>(CO.C<sub>6</sub>H<sub>4</sub>Cl). [11°] (Mosso).

(4:2:1)-**Di-chloro-phenol** C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(OH) [4:2:1] [42°]. (210°).

*Formation*.—1. By chlorinating phenol (Laurent, *A. Ch.* [2] 63, 27; [3] 3, 210; F. Fischer, *Z.* [2] 4, 386; *A. Suppl.* 7, 180).—2. By adding HCl to a mixture of phenol (1 mol.) and sodium hypochlorite (2 mols.), the (6:2:1)-isomeride is formed simultaneously (Chandelon, *B.* 16, 1751).

*Properties*.—White needles. Sol. alcohol and ether, nearly insol. water. Expels CO<sub>2</sub> from boiling aqueous Na<sub>2</sub>CO<sub>3</sub>, but in the cold it is pptd. from its salts by CO<sub>2</sub>. PCl<sub>5</sub> gives tri-chloro-benzene [16°].

*Salts*.—NH<sub>4</sub>O.C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>: needles (from hot NH<sub>4</sub>Aq).—KA' 3aq: decomposed by water at 70°, giving off *p*-chloro-phenol.—HOPbA'.—AgA'.

*Ethyl ether* C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(OEt). (237°).

*Acetyl derivative* C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(OAc). (245°).

*Benzoyl derivative* C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(OBz). [97°].

*Phthalyl derivative* C<sub>6</sub>H<sub>3</sub>(CO.C<sub>6</sub>H<sub>4</sub>Cl)<sub>2</sub>. [108°] (Mosso, *Ann. Chim. Farm.* 87, 184).

(6:2:1)-**Di-chloro-phenol** C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>(OH) [6:2:1] [53°]. (218°).

*Formation*.—1. Together with the (4:2:1) isomeride by adding HCl to a mixture of phenol (1 mol.) and sodium hypochlorite (2 mols.) (Chandelon, *B.* 16, 1752).—2. From di-chloro-*p*-amido-phenol by displacing NH<sub>2</sub> by Cl through the diazo-reaction (Seifart, *A. Suppl.* 7, 203; *Z.* [2] 5, 450).

*Properties*.—Needles. Sol. alcohol and ether, nearly insol. water.

Tri-chloro-phenol C<sub>6</sub>H<sub>2</sub>Cl<sub>3</sub>(OH) [6:4:2:1]. [68°]. (244°). S. 0.51 at 14°; 243 at 96°.

*Formation*.—1. By chlorination of phenol (Laurent, *A. Ch.* [2] 63, 27; [3] 3, 497), of saligenin (the product being distilled with conc. H<sub>2</sub>SO<sub>4</sub>, Piria, *A.* 56, 47), of aniline (Hofmann, *A.* 53, 8), of indigo (Erdmann, *J. pr.* 19, 382; 22, 276; 25, 473), of phenol sulphonic acid (Vogel, *Z.* 1865, 529), or of phenyl benzoate (Vogel, *Z.* 1865, 529), or of phenyl benzoate (Vogel, *Z.* 1865, 529) (Sintenis, *A.* 161, 338).—2. By the action of NaOCl upon (2, 6, 1)-di-chloro-phenol [65°], and upon (2, 4, 1)-di-chloro-phenol [48°] (Chandelon, *Bl.* [2] 89, 138).

*Properties*.—Needles or prisms. Acid to litmus.

*Reactions*.—1. HNO<sub>3</sub> forms di-chloro-quinone [120°]; alcohol and N<sub>2</sub>O, produce the same

body.—2.  $\text{PCl}_5$  or  $\text{FeCl}_3$  from tetra-chloro-benzene.—3.  $\text{HCl}$  and  $\text{KClO}_3$  give tetra-chloro-quinone.  $\text{CrO}_3$  and  $\text{HOAc}$  produces the same body (Levy & Schults, A. 210, 180).—4.  $\text{K}_2\text{SO}_4$  at  $170^\circ$  gives chloro-phenol disulphonic acid and di-chloro-phenol sulphonic acid (Armstrong & Harrow, C. J. 29, 474).—5.  $\text{Br}$  gives  $\text{C}_6\text{H}_4\text{Cl}_2\text{OBr}$  [ $99^\circ$ ] (Benedikt, M. 4, 235).

Salts.— $\text{NH}_4\text{C}_6\text{H}_4\text{Cl}_2\text{O}$ : needles; v. sl. sol. cold water.— $\text{KA}'$  3aq.— $\text{MgA}'$ , 2aq.— $\text{BaA}'$ , 4aq: radiate groups of laminae.— $\text{PbA}'$ ,—( $\text{PbA}'$ ),  $\text{PbO}$ .  $\text{AgA}'$ : yellow amorphous pp.

Ethyl ether  $\text{C}_6\text{H}_4\text{Cl}_2\text{O}(\text{OEt})$ : [ $44^\circ$ ]. ( $240^\circ$ ). (Faust, A. 149, 152; Lampert, J. pr. [2] 83, 381).

Acetyl derivative  $\text{C}_6\text{H}_4\text{Cl}_2\text{O}(\text{OAc})$ . ( $262^\circ$ ).

Propionyl derivative  $\text{C}_6\text{H}_4\text{Cl}_2\text{O}(\text{O(CO.C}_2\text{H}_5))$ : ( $268^\circ$  uncor.), colourless heavy liquid.

Butyryl derivative  $\text{C}_6\text{H}_4\text{Cl}_2\text{O}(\text{O(CO.C}_2\text{H}_5))$ : ( $274^\circ$  uncor.).

Valeryl derivative  $\text{C}_6\text{H}_4\text{Cl}_2\text{O}(\text{O(CO.C}_2\text{H}_5))$ : ( $383^\circ$  uncor.).

Benzoyl derivative  $\text{C}_6\text{H}_4\text{Cl}_2\text{O.Bz}$ : [ $70^\circ$ ]; colourless needles; sl. alcohol and ether, insol. water.

Phthalyl derivative  $\text{C}_6\text{H}_4\text{Cl}_2\text{O} \begin{smallmatrix} \diagup \text{CO} \diagdown \\ \diagdown \text{CO} \diagup \end{smallmatrix} \text{C}_6\text{H}_4$ : [ $194^\circ$ ]; v. sol. chloroform, sl. sol. alcohol and ether, insol. water (Dacomo, B. 18, 1168).

Tri-chloro-phenol  $\text{C}_6\text{H}_3\text{Cl}_3(\text{OH})$ . [ $54^\circ$ ]. ( $253^\circ$  uncor.). From tri-chloro-*p*-amido-phenol (Lampert, J. pr. [2] 83, 378). Also from phenol and  $\text{NaOCl}$  (Chandelon, Bl. [2] 38, 119). Silky needles (from dilute alcohol). Volatile with steam.  $\text{HNO}_3$  gives no quinone, but a nitro-derivative [ $146^\circ$ ].  $\text{PCl}_5$  gives  $\text{C}_6\text{H}_3\text{Cl}_3$ .

Ethyl ether  $\text{C}_6\text{H}_3\text{Cl}_3(\text{OEt})$ : ( $246^\circ$  uncor.).

Acetyl derivative  $\text{C}_6\text{H}_3\text{Cl}_3(\text{OAc})$ : ( $259^\circ$  uncor.).

Tetra-chloro-phenol  $\text{C}_6\text{H}_2\text{Cl}_4(\text{OCl})$  [ $6:4:2:1$ ] or  $\text{C}_6\text{H}_2\text{Cl}_4(\text{Cl})\text{O}$ . 'Tri-chloro-phenol chloride' [ $119^\circ$ ]. Formed by passing  $\text{Cl}$  into tri-chloro-phenol suspended in fuming aqueous  $\text{HCl}$  (Benedikt, M. 4, 235). Trimetric pyramids;  $a:b:c = 1:61:61$ . May be distilled. Conc.  $\text{KOH}$  turns the crystals blue, and on boiling forms tri-chloro-phenol. Hot conc.  $\text{H}_2\text{SO}_4$  gives tri-chloro-phenol and tetra-chloro-quinone.

Penta-chloro-phenol  $\text{C}_6\text{Cl}_5(\text{OH})$  [ $188^\circ$ ].

Formation.—1. By the action of chlorine on an alcoholic solution of tri-chloro-phenol, chloroisatin, or di-chloro-isatin (Erdmann, J. pr. 22, 272; Laurent, A. Chm. [3] 3, 497).—2. From phenol and chloride of iodine (Schützenberger, Bl. [2] 4, 102).—3. By passing chlorine into a mixture of phenol or tri-chloro-phenol and  $\text{SbCl}_5$  at  $200^\circ$  (Mers & Weith, B. 6, 458; Benedikt & Schmidt, M. 4, 606).—4. Obtained by heating hexa-chloro-benzene with a glycerin solution of  $\text{NaOH}$  at  $250^\circ$ – $280^\circ$ . Properties.—Sublimes in long white needles.  $\text{HNO}_3$  forms tetra-chloro-quinone.  $\text{PCl}_5$  gives  $\text{C}_6\text{Cl}_5$ .

Salts.— $\text{C}_6\text{Cl}_5\text{ONa}$ .— $\text{KA}'$ .— $\text{AgA}'$ .

Methyl ether  $\text{C}_6\text{Cl}_5\text{O}(\text{OMe})$ : [ $108^\circ$ ]; long white needles; v. sol. alcohol; sublimable.

Acetyl derivative  $\text{C}_6\text{Cl}_5\text{O}(\text{OAc})$ : [ $148^\circ$ ]; fine white needles; v. sol. alcohol; sublimable (Weber & Wolff, B. 18, 835).

Dichloride  $\text{C}_6\text{Cl}_4(\text{OH})\text{Cl}$ . [ $78\frac{1}{2}^\circ$ – $80^\circ$ ]. Formed in the chlorination of *m*-chloro-acetanil-

ide in acetic acid (Beilstein, B. 11, 2182). Large colourless pillars. Difficultly soluble in 50 p.p. acetic acid, easily in  $\text{C}_6\text{H}_6$ ,  $\text{CHCl}_3$ ,  $\text{CS}_2$ , alcohol, &c. Alkalis decompose it entirely. On heating with alcohol per-chloro-phenol is formed.

Hexa-chloro-phenol  $\text{C}_6\text{Cl}_6\text{O}$ . [ $46^\circ$ ]. Formed by passing  $\text{Cl}$  into a solution of penta-chloro-phenol in dilute  $\text{HCl}$  (Benedikt & Schmidt, M. 4, 607). Golden-yellow crystals; gives off chlorine on heating. Tin and  $\text{HCl}$  re-convert it into penta-chloro-phenol.

Dichloride  $\text{C}_6\text{Cl}_4\text{O}$ . [ $102^\circ$ ]. Formed by chlorinating penta-chloro-phenol in acetic acid solution (B. & S.). Prisms (from ligroin).

Hexa-chloro-phenol  $\text{C}_6\text{Cl}_6\text{O}$ . [ $106^\circ$ ]. From penta-chloro-aniline by chlorination in acetic acid solution (Langer, A. 215, 122). Yellowish prisms (from ligroin).

Per-chloro-diphenol 9. OCTO-CHLORO-DI-OXY-DIPHENYL.

*o*-CHLORO-PHENOL ( $\gamma$ )-SULPHONIC ACID,  $\text{C}_6\text{H}_4\text{ClSO}_3$ , i.e.  $\text{C}_6\text{H}_4\text{Cl}(\text{OH})\text{SO}_3\text{H}$ . From *o*-chloro-phenol and fuming  $\text{H}_2\text{SO}_4$  (Krämers, A. 173, 331). Small colourless plates or cubes (containing aq). V. e. sol. water and alcohol. It begins to decompose at  $80^\circ$ .  $\text{FeCl}_3$  colours its solutions violet.  $\text{HNO}_3$  forms chloro-di-nitro-phenol [ $111^\circ$ ].

Salts.— $\text{KA}'$  3aq: S. (of  $\text{KA}'$ ) 14 at  $9^\circ$ .— $\text{K}_2\text{C}_6\text{H}_4\text{ClSO}_3$  3aq: deliquescent laminae.— $\text{NaA}'$  aq.— $\text{Na}_2\text{C}_6\text{H}_4\text{ClSO}_3$  3aq.— $\text{CaA}'$ , 2aq.— $\text{CaC}_6\text{H}_4\text{ClSO}_3$  3aq: efflorescent crystalline aggregates; S. 38 at  $12^\circ$ .— $\text{BaA}'$ , 1aq: granular aggregates of crystals.— $\text{PbA}'$ , 4aq.— $\text{PbC}_6\text{H}_4\text{ClSO}_3$  aq.— $\text{CuA}'$ , 4aq: bluish-green trimetric prisms.

*o*-Chloro-phenol ( $\delta$ )-sulphonic acid  $\text{C}_6\text{H}_3\text{Cl}(\text{OH})\text{SO}_3\text{H}$ . Formed, together with the preceding, when the sulphonation is effected in the cold by fuming  $\text{H}_2\text{SO}_4$  (1 pt.) mixed with conc.  $\text{H}_2\text{SO}_4$  (1½ pts.) (K.).— $\text{KA}'$ : small plates.  $\text{CaC}_6\text{H}_3\text{ClSO}_3$  2aq: small needles; S. 225 at  $11^\circ$ .

*o*-Chloro-phenol ( $\delta$ )-sulphonic acid  $\text{C}_6\text{H}_3\text{Cl}(\text{OH})\text{SO}_3\text{H}$ . Obtained, in small quantity, in sulphonating impure *p*-chloro-phenol (Petersen & Baehr-Praderi, A. 157, 121). Potash-fusion gives pyrogallol.  $\text{FeCl}_3$  colours its neutral solutions violet.  $\text{HNO}_3$  gives chloro-di-nitro-phenol [ $81^\circ$ ].— $\text{KA}'$ : stellate groups of short prisms; less soluble than potassium *p*-chloro-phenol sulphonate.

*p*-Chloro-phenol ( $\alpha$ )-sulphonic acid  $\text{C}_6\text{H}_4\text{Cl}(\text{OH})(\text{SO}_3\text{H})$ . [ $76^\circ$ ]. From *p*-chloro-phenol and fuming  $\text{H}_2\text{SO}_4$  at  $100^\circ$  (Petersen & Baehr-Praderi, A. 157, 121). Glittering plates (containing aq). Begins to decompose at  $100^\circ$ . Gives a bluish-violet colour with  $\text{FeCl}_3$ . Potash-fusion gives pyrogallol and a trace of hydroquinone.  $\text{HNO}_3$  forms chloro-nitro-phenol sulphonic acid (Armstrong, B. 7, 404) and chloro-di-nitro-phenol [ $81^\circ$ ].

Salts.— $\text{KA}'$  2aq: flat monoclinic prisms; S. 10.8 at  $20^\circ$ ; 44.3 at  $100^\circ$ .— $\text{KA}'$  aq.— $\text{KA}'$  (from alcohol): needles.— $\text{NaA}'$ : groups of needles.— $\text{LiA}'$  aq.— $\text{NH}_4\text{A}'$ : [ $280^\circ$ ].— $\text{BaA}'$ ,— $\text{BaC}_6\text{H}_3\text{ClSO}_3$  2aq.— $\text{CaA}'$ , 2aq: easily soluble needles.— $\text{MgA}'$ , 6aq: small flat plates or needles.— $\text{CuA}'$ , 6aq: greenish-white needles, v. e. sol. water.

Ethyl derivative  $\text{C}_6\text{H}_3\text{Cl}(\text{OEt})\text{SO}_3\text{H}$ .

**Salt.**—KA': stellate groups of needles.

**Chloro-phenol disulphonic acid**

$\text{C}_6\text{H}_3\text{Cl}(\text{OH})(\text{SO}_3\text{H})_2$  [4:1:6:2]. Formed, together with di-chloro-phenol sulphonic acid, by heating tri-chloro-phenol with  $\text{K}_2\text{SO}_4$  at  $170^\circ$  (Armstrong a. Harrow, *C. J.* 29, 474). The same acid appears to be formed by sulphonating *p*-chloro-phenol at  $100^\circ$  (Petersen a. Baehr-Praderi, *A.* 157, 153). Conc.  $\text{HNO}_3$  forms chloro-di-nitro-phenol [81°].

**Di-chloro-phenol sulphonic acid**

$\text{C}_6\text{H}_3\text{Cl}_2(\text{OH})(\text{SO}_3\text{H})$  [4:2:1:6]. From (4,2,1)-di-chloro-phenol and  $\text{ClSO}_3\text{H}$  [43°] (Armstrong, *C. J.* 25, 98). Formed also by chlorinating phenol *o*-sulphonic acid; and by heating tri-chloro-phenol with  $\text{K}_2\text{SO}_4$  at  $170^\circ$  (Armstrong a. Harrow).  $\text{HNO}_3$  (S.G. 1.36) forms di-chloro-nitro-phenol [121°].

**Di-chloro-phenol sulphonic acid**

$\text{C}_6\text{H}_3\text{Cl}_2(\text{OH})(\text{SO}_3\text{H})$  [2:6:1:4]. Formed by chlorinating phenol *p*-sulphonic acid (Kolbe a. Gauche, *A.* 147, 76) and by sulphonating (2,6,1)-di-chloro-phenol. Deliquescent trimetric tables or prisms.  $\text{HNO}_3$  forms di-chloro-nitro-phenol and chloro-di-nitro-phenol [111°] (Faust, *Z.* 1871, 838; Armstrong, *C. J.* 24, 1112).— $\text{BaA'}$ , 2aq (dried at  $100^\circ$ ).

**Tri-chloro-phenol sulphonic acid**

$\text{C}_6\text{HCl}_3(\text{OH})(\text{SO}_3\text{H})$ . From tri-chloro-phenol and  $\text{ClSO}_3\text{H}$  (Armstrong, *C. J.* 25, 97; cf. Kekulé, *K.* 3, 238). Its aqueous solutions decompose with deposition of tri-chloro-phenol.

**TRI-CHLORO-PHENOMALIC ACID**

$\text{C}_6\text{H}_2\text{Cl}_3\text{O}$ , i.e.  $\text{CCl}_3\text{CO.CH.C}_6\text{H}_2\text{Cl}_3$  or  $\text{CH}_2\text{Cl}(\text{OH}).\text{CCl}_3$   
 $\text{I} > \text{O}$  (Anschütz, *A.* 239, 176). Tri-chloro-CH.CO

**acetyl-acrylic acid.** [132°]. From benzene (80g.),  $\text{H}_2\text{SO}_4$  (1,200 g.) and water (600 g.), to which  $\text{KClO}_4$  (120 g.) is slowly (in 5 days) added with gentle shaking. The benzene is then separated and evaporated, the residue is extracted with water and the acid (6 g.) extracted from the water by ether (Carius, *A.* 140, 317; 142, 131; Kekulé a. O. Strecker, *A.* 223, 179). Quinone may be substituted for benzene.

**Properties.**—Glittering plates (from water). May be sublimed. Is volatile with steam.

**Reactions.**—1. Warmed with baryta it gives chloroform and baric maleate.—2. Combines with bromine in chloroform with formation of  $\text{CCl}_3\text{CO.CHBr.CHBr.CO}_2\text{H}$  [97-5°]. This is sl. sol. water, v. sol. alcohol, ether, and chloroform. Boiled with lime water, it gives chloroform and inactive calcic tartrate.

**Theory of Formation.**—Kekulé supposes that it is produced from chloro-quinone, and if this is written  $\text{CO} < \frac{\text{CH}_2\text{CH}}{\text{CH}_2\text{CHCl}} > \text{CO}$  the conversion of it into  $\text{CO} < \frac{\text{CH}_2\text{OH}}{\text{OH.CCl}_3} > \text{CO}$  does not appear very difficult to understand.

**CHLORO-PHENOXY-ACETIC ACID**

$\text{C}_6\text{H}_4\text{ClO}$ , i.e.  $\text{C}_6\text{H}_4\text{ClO.CH}_2\text{CO}_2\text{H}$  [162°]. From phenoxy-acetic acid by successive treatment with  $\text{PCl}_5$  and water (Michael, *J. pr.* [3] 85, 96). Trimetric prisms (from water).

***o*-CHLORO-DIPHENYL**  $\text{C}_{12}\text{H}_9\text{Cl}$  i.e.

$\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{Cl}$  [3:1]. [84°]. (897°). Formed, together with the *p*-isomeride, by passing chlorine into diphenyl mixed with  $\text{SbCl}_5$  (Krämers, *A.*

189, 142). Monoclinic crystals; v. sol. ligroin.  $\text{CrO}_3$  gives *o*-chloro-benzoic acid.

***m*-Chloro-diphenyl**  $\text{C}_{12}\text{H}_9\text{Cl}$  [3:1]? [89°]. Formed by heating  $\text{C}_6\text{H}_5\text{OK}$  with calcium *m*-chloro-benzoic acid (Fannkueh, *J. pr.* [2] 6, 106).

***p*-Chloro-diphenyl**  $\text{C}_{12}\text{H}_9\text{Cl}$  [4:1]. [75°]. (283°). Formed by chlorinating diphenyl (v. *supra*) or by treating *p*-oxy-diphenyl with  $\text{PCl}_5$  (G. Schultz, *B.* 7, 52). Thin plates (from ligroin). Smells like oranges. May be oxidised to *p*-chloro-benzoic acid.

**Di-*p*-chloro-diphenyl**  $[\text{4:1}]\text{C}_6\text{H}_4\text{Cl}_2\text{C}_6\text{H}_4[\text{1:4}]$  [148°]. (c.  $817^\circ$  act.).

**Formation.**—1. Amongst the products of the action of  $\text{PCl}_5$  on di-*p*-oxy-diphenyl (Schmidt a. Schultz, *B.* 12, 494; *A.* 207, 339).—2. From di-amido-diphenyl (benzidine) by displacement of  $\text{NH}_2$  by  $\text{Cl}$  through the diazo-reaction (Griess, *Tr.* 1864, iii. 780); e.g. by heating tetrazo-diphenyl with a large excess of  $\text{HCl}$ ; the yield being 16 p.c. of the theoretical (Gasirowski a. Wayss, *B.* 18, 1941).—3. By chlorinating diphenyl (Krämers, *A.* 189, 189, 145).—4. By passing chloro-benzene through a red-hot tube.

**Properties.**—Prisms or needles; insol. water, sl. sol. alcohol, v. sol. ether.  $\text{CrO}_3$  gives *p*-chloro-benzoic acid.

**Penta-chloro-diphenyl**  $\text{C}_{12}\text{HCl}_5$ . [179°]. Formed together with other products by the action of  $\text{PCl}_5$  on di-*p*-oxy-diphenyl (Schmidt a. Schultz, *B.* 12, 495; cf. Doeberner, *B.* 9, 180). Long needles. Sublimable.

**Per-chloro-diphenyl**  $\text{C}_{12}\text{Cl}_{10}$ . Prepared by exhaustive chlorination of diphenyl in presence of  $\text{SbCl}_5$  or iodine (Ruoff, *B.* 9, 1491; Weber a. Söllcher, *B.* 16, 882; Merz a. Weith, *B.* 16, 2881). Formed also by exhaustive chlorination of ditolyl (Merz a. Weith, *B.* 12, 677), benzidine, carbazole (Zetter, *B.* 10, 1233), and phenanthraquinone (Merz a. Weith, *B.* 16, 2871). Long tables or prisms. Does not melt below  $270^\circ$ . V. sl. sol. alcohol or ether. Not attacked by  $\text{SbCl}_5$  even at  $350^\circ$ . Alcoholic  $\text{NaOH}$  at  $160^\circ$  gives  $\text{C}_{12}\text{Cl}_8(\text{OH})_2$ .

***o*-CHLORO-PHENYL-ACETIC ACID**  $\text{C}_6\text{H}_4\text{ClO}$ , i.e.  $\text{C}_6\text{H}_3\text{Cl}(\text{OH}).\text{CO}_2\text{H}$ . [78°].

**Formation.**—1. From mandelic acid  $\text{C}_6\text{H}_5\text{CH}(\text{OH}).\text{CO}_2\text{H}$  and  $\text{HCl}$  at  $140^\circ$  (Radziszewski, *B.* 2, 208).—2. From benzoic aldehyde by conversion into  $\text{PhCH}(\text{OH})\text{CN}$  by  $\text{KCN}$  and  $\text{HCl}$ , the mandelo-nitrile being then treated with  $\text{HCl}$  (Spiegel, *B.* 14, 235; R. Meyer, *A.* 220, 41).—3. From  $\text{C}_6\text{H}_5\text{CH}(\text{OH}).\text{NO}_2$  and fuming  $\text{HCl}$  at  $100^\circ$  (Priebs, *A.* 225, 837).

**Properties.**—Trimetric tables; sl. sol. cold water and ligroin, v. e. sol. alcohol and ether. Sodium amalgam converts it into phenyl-acetic acid. Boiling aqueous  $\text{KOH}$  forms mandelic acid. Phenyl-hydrazine forms benzylidene-phenyl-hydrazine  $\text{C}_6\text{H}_5\text{CH}:\text{N}:\text{HPh}$  (Reisert, *B.* 17, 1452). The salts are unstable.

**Methyl ether**  $\text{MeA'}$  (248° cor.). Oil (Meyer a. Boner, *B.* 14, 2892).

***p*-Chloro-phenylacetic acid**  $\text{C}_6\text{H}_4\text{ClCH}_2\text{CO}_2\text{H}$  [104°]. Prepared by saponification of the nitrile (Neuhof, *A.* 147, 346; Jackson a. Field, *P. Am. A.* 14, 68). Also by treating phenyl-acetic acid with  $\text{Cl}$  in sunshine (Radziszewski, *B.* 2, 208). Long needles (from water). V. sol. benzene.

water, alcohol, and ether.—AgA': curdy mass.—CaA', aq.

**Amide**  $C_6H_4Cl.CH_2.CONH_2$ . [175°]. Tables (from alcohol). V. sol. alcohol and ether, sl. sol. hot water.

**Nitrile**  $C_6H_4Cl.CH_2.CN$ . [29°]. From *p*-chloro-benzyl bromide by heating with alcoholic KOH (Jackson & Field, *Am.* 2, 88). Prisms; sol. alcohol and ether.

**Di- $\alpha$ -chloro-phenyl-acetic acid**  $C_6H_3Cl_2.CO_2H$ . [68°]. Prepared by the action of  $PCl_5$  on phenyl-glyoxylic ether and subsequent saponification (Claisen, *B.* 12, 630). Small tables. V. sol. water, alcohol, and ether.

**Ethyl ether** A'Et. (263°–266°).

**Nitrile**  $C_6H_3Cl_2.CN$ . (224°). From benzoyl cyanide and  $PCl_5$  (C).

**DI- $\alpha$ -CHLORO-PHENYL-ACETIC ALDEHYDE**  $C_6H_3Cl_2.CHO$ . (235°). From chloral, benzene, and  $AlCl_3$  at 70°. The product is treated with water and fractionally distilled *in vacuo*, when the compound  $C_6H_3Cl_2.CHCl(OH)$  passes over at 180°. By the action of KOH it is converted into the aldehyde by removal of HCl (Combes, *C. R.* 98, 678). Liquid. Reduces Fehling's solution and combines with  $NaHSO_3$ , although with difficulty. Benzene and  $AlCl_3$  convert the aldehyde into tri-phenyl-methane.

**CHLORO-PHENYL-ACRYLIC ACID** *v.* CHLORO-CINNAMIC ACID.

**CHLORO-PHENYL-AMIDO-CHLORO-NAPHTHOQUINONE** *v.* CHLORO-NAPHTHOQUINONE-CHLORO-ANILIDE.

**CHLORO-PHENYL-AMIDO-HYDRONAPHTHOQUINONE**  $C_{10}H_6Cl_2ClNO$ , *i.e.*  $C_{10}H_6Cl_2(OH)(NHPh)$ . [171°]. From chloro-naphthoquinone anilide and conc. aqueous  $SnCl_2$  (Knapp & Schultz, *A.* 210, 190).

**Acetyl derivative** [169°].

**CHLORO-DI-PHENYL-DI-AMIDO-HYDROQUINONE**  $C_{12}H_8Cl_2O_2$ , *i.e.*  $C_6H_4Cl(OH)_2(NHPh)_2$ . From chloro-di-phenyl-di-amido-quinone, conc.  $SnCl_2$ , Ag, and alcohol (Knapp & Schultz, *A.* 210, 181). Slender needles. Decomposes about 223°. Readily oxidised to the corresponding quinone.

**Di-chloro-di-phenyl-di-amido-hydroquinone**  $C_{12}H_8Cl_4N_2O_2$ , *i.e.*  $C_6Cl_2(NHPh)_2(OH)_2$ . Formed by boiling di-chloro-di-phenyl-di-amido-quinone  $C_6Cl_2(NHPh)_2O$  with conc. aqueous  $SnCl_2$  (Knapp & Schultz, *A.* 210, 181). Slender needles, v. sol. water. Oxidation gives  $C_{12}H_8Cl_4(NHPh)_2O_2$ . Boiling  $Ac_2O$  gives long needles of  $C_{12}H_8Cl_4N_2O_2$  [255°].

***p*-CHLORO-DI-PHENYL-DI-*p*-AMIDO-TRI-PHENYL-METHANE**  $C_{18}H_{15}Cl_2CH_2(NHPh)_3$ . Not isolated in a pure state. Formed by heating together diphenylamine and *p*-chloro-benzaldehyde in presence of  $ZnCl_2$ . On oxidation it gives a green dye-stuff (Kaeswurm, *B.* 19, 745).

**TRI-CHLORO-TRI-PHENYL-TRI-AMIDO-DI-PHENYL-TOLYL-CARBINOL** *v.* TRI-CHLORO-TRI-PHENYL-ROBINILAN.

**CHLORO-PHENYL-AMIDO-QUINONES** *v.* ANILIDES OF CHLORO-QUINONES.

***p*-CHLORO-DI-PHENYL-AMINE**  $PhNHCH_2Cl$ . [74°]. Formed by treating diazotised *p*-amido-di-phenyl-amine with cuprous chloride (Ikuta, *A.* 245, 286). Long prisms. V. sl. sol. water, v. sol. ether, alcohol, benzene,

petroleum ether. Yields a nitrosamine  $PhN(NO)C_6H_4Cl$  [88°], v. sol. alcohol and ether, which on standing with alcoholic HCl is converted into the isomeric *p*-nitroso-chloro-di-phenyl-amine  $C_6H_4(NO)NHCH_2Cl$  [159°] green plates (from benzene).

**Di-chloro-di-phenyl-amine**  $NH(C_6H_4Cl)_2$ . [80°]. From the benzoyl derivative and alcoholic KOH at 160° (Claus & Schaare, *B.* 15, 1286). Needles.

**Benzoyl derivative**  $NBz(C_6H_4Cl)_2$ . [153°]. From benzoyl-di-phenyl-amine by chlorination (C. a. S.; *cf.* Claus, *B.* 14, 2368). Needles (from alcohol).

**Tetra-chloro-di-phenyl-amine**  $NH(C_6H_2Cl_4)_2$ . [134°]. Formed by passing Cl into a solution of di-phenyl-amine in HOAc (Gnehm, *B.* 8, 1040). Prisms or needles.

**Per-chloro-tri-phenyl-amine**  $N(C_6Cl_5)_3$ . From tri-phenyl-amine by exhaustive chlorination (Ruoff, *B.* 9, 1494). Needles (from benzene-alcohol).

**DI-CHLORO-PHENYL-ANTHRANOL**

$C_{12}H_8Cl_2O$  *i.e.*  $C_6H_3Cl_2 \begin{matrix} \diagup C_6H_4Cl \\ \diagdown C(OH) \end{matrix}$   $C_6H_4Cl$ . [170°].

From  $CO \begin{matrix} \diagup C_6H_4Cl \\ \diagdown C(OH) \end{matrix} C_6H_4Cl$  (phenolphthalidein chloride), acetic acid, and zinc-dust (Baeyer, *A.* 202, 95). Needles (from alcohol). V. sl. sol. alcohol; m. sol. acetone and ether, with bluish-green fluorescence.

**Dihydride**  $C_6H_3Cl_2 \begin{matrix} \diagup CH(C_6H_4Cl) \\ \diagdown CH(OH) \end{matrix} C_6H_4Cl$ .

**Hydrophenolphthalidin chloride**. [56°]. From the preceding by heating in alcoholic solution with sodium amalgam (B.). Long needles (from  $CS_2$ ).

**PER-CHLORO-DI-PHENYL-BENZENE**

$C_{12}Cl_{10}$ . Formed by exhaustive chlorination of di-phenyl-benzene by means of  $SbCl_5$  (Merz & Weith, *B.* 16, 2884). Colourless needles. V. sol. hot nitrobenzene, sl. sol. alcohol, ether, and acetic acid.

**Per-chloro-tri-phenyl-benzene**  $C_{18}Cl_{15}$ . Formed by exhaustive chlorination of tri-phenyl-benzene by means of  $SbCl_5$  (Merz & Weith, *B.* 16, 2883). Colourless needles. V. sol. hot nitrobenzene, sl. sol. ether, benzene, and alcohol. It is only slightly attacked by  $HNO_3$  at 850°.

**CHLORO-PHENYL BENZYL OXIDE**

$C_6H_4Cl.O.CH_2Ph$ . [71°]. From phenyl benzyl oxide and Cl in presence of  $HgO$  (Sintenis, *A.* 161, 338). Long needles (from alcohol).

**TRI-CHLORO-DI-PHENYL-BUTANE**

$C_{18}H_{15}Cl_3$ , *i.e.*  $CH_3.CHCl.CCl_2.CHPh_3$ . [80°]. S. (ether) 50; (alcohol) 2. From tri-chloro-butyric aldehyde, benzene, and  $H_2SO_4$  (Hepp, *B.* 7, 1420). Monoclinic prisms (from ether-alcohol).

**TRI-CHLORO-DI-PHENYL-BUTANE DISULPHONIC ACID**  $C_{18}H_{15}Cl_3(SO_3H)_2$ . From  $C_{18}H_{15}Cl_3$  and fuming  $H_2SO_4$  (Hepp, *B.* 7, 1420).—BaA<sup>4</sup>.

**CHLORO-DI-PHENYL-*tert*-BUTYL ALCOHOL**  $CClPh_2.CMe_2.OH$ . (239°). From liquid acetone-chloroform, benzene, and  $AlCl_3$  (Willgerodt, *J. pr.* [2] 87, 362).

**Di-chloro-phenyl-*tert*-butyl alcohol**  $CClPh.CMe_2.OH$ . (217°). From acetone-chloroform, benzene, and  $AlCl_3$  (Willgerodt & Gieseler, *J. pr.* [2] 87, 367). Liquid.

**CHLORO-*o*-PHENYLENE-DIAMINE**

$C_6H_4ClN_2$ , i.e.  $C_6H_4Cl(NH_2)_2$  [4:2:1]. [72°]. From chloro-di-nitro-benzene [39°] by reduction with tin and HCl (Laubenheimer, B. 9, 773). Laminæ.  $FeCl_3$  gives a red colour and a brown pp.

Chloro-*m*-phenylene-diamine  $C_6H_4Cl(NH_2)_2$  [4:3:1]. [86°]. From chloro-di-nitro-benzene [50°], tin, and HCl (Beilstein & Kurbatoff, A. 197, 76). Needles (from ligroin).

Chloro-*p*-phenylene-diamine  $C_6H_4Cl(NH_2)_2$  [2:4:1]. [123-5°]. From di-chloro-nitro-aniline [188°], tin, and HCl (Witt, B. 8, 145). Flat needles.—B'HCl: long needles.

Di-chloro-*o*-phenylene-diamine  $C_6H_3Cl_2(NH_2)_2$  [5:3:2:1]. [60-5°]. From di-chloro-nitro-aniline [100°], tin, and HCl (Witt, B. 7, 1604). Long flexible needles (from alcohol).

Di-chloro-*p*-phenylene-diamine  $C_6H_3Cl_2(NH_2)_2$  [5:2:4:1]. [164°]. Formed, together with dimethyl-*p*-phenylene-diamine and di-chloro-di-methyl-*p*-phenylene-diamine, by boiling nitroso-di-methyl-aniline with HCl (S.G. 1-2) (Möhlau, B. 19, 2010). Colourless glistening prisms. By  $K_2Cr_2O_7$  and  $H_2SO_4$  it is oxidised to di-chloro-quinone [169°]. The dilute HCl solution on treatment with chloride of lime yields di-chloro-quinone-di-chlorimide [134°].

Tetra-chloro-*p*-phenylene diamine  $C_6Cl_4(NH_2)_2$  [218°]. Formed by boiling quinone dichlorimide with HCl (S.G. 1-2) (Krause, B. 12, 51). Red needles (from dilute alcohol).

**DI-CHLORO-DI-PHENYLENE KETONE**  
 $C_{12}H_8Cl_2O$ . [168°]. From di-chloro-fluorene by  $CrO_3$  (Hodgkinson & Matthews, C. J. 43, 170).

**DI-*a*-CHLORO-PHENYLENE-DI-METHYL-DI-MALONIC ETHER**  $C_{12}H_8(CH_3COO)_2(CO_2Et)_2$ . *v. Exo-di-chloro-xylylene-malonic ether.*

**TETRA-CHLORO-PHENYLENE-DI-METHYL OXIDE**  $C_{12}H_8Cl_4O$ . [218°]. V.D. 8.6 (calc. 8.9). From tetra-chloro-phthalic acid, HI, and P at 230° (Gfæbe, A. 238, 331). Needles (from benzene).

Octo-chloro-phenylene-di-methyl oxide  
 $C_8Cl_8(CCl_2)_2O$ . [140°]. From tetrachloro-phthalic anhydride and  $PCl_5$  at 200° (G).

**DI-CHLORO-PHENYLENE-(*a*)-NAPHTHYLENE-OXIDE**  $C_{12}H_8Cl_2O$ . [245°]. Prepared by the action of  $PCl_5$  on phenylene-(*a*)-naphthylene-oxide (Arr, B. 13, 1737). Fine white needles. V. sol. alcohol and ether, sl. sol. benzene.

**TETRA-CHLORO-PHENYLENE OXIDE**  
 $C_{12}Cl_8O$  (?) [320°]. (above 360°). Formed by distilling potassium penta-chloro-phenol  $C_6Cl_5OK$  (Merz & Weith, B. 5, 461). Flat needles. V. sl. sol. alcohol and ether. Not affected by  $PCl_5$  at 250° or by sodium-amalgam.

**CHLORO-*p*-PHENYL-ETHANE** *v.* **CHLORO-*o*-PHENYL-BENZENE.**

Chloro-di-phenyl-ethane  $C_{12}H_{10}Cl$  i.e.  $CH_3CH_2CHPh_2$ . From di-chloro-di-ethyl oxide  $CH_3CH_2CHClOEt$ , benzene, and  $H_2SO_4$  (Hepp, B. 6, 1439). Liquid. Splits up on distillation or treatment with alcoholic KOH into HCl and  $C_6H_5$ .

Di-*p*-chloro-di-phenyl-ethane  
 $C_6H_3Cl_2CH_2CH_2C_6H_4Cl$ . **Di-chloro-dibenzyl.** [112°]. Formed by passing chlorine over a solid cake of dibenzyl (150 pts.) and iodine (1 pt.) till the cake liquefies. This is distilled and the pro-

duct crystallised from alcohol (Kade, J. pr. [2] 19, 462). Glittering plates which feel greasy. Sol. alcohol, ether, and chloroform. Chromic mixture oxidises it to *p*-chloro-benzoic acid.

(*a*)-Di-*exo*-chloro-*s*-di-phenyl ethane  
 $C_6H_5CHClCHClC_6H_5$ . **Stilbene (*a*)-chloride.** [193°]. Formed, together with the (*β*)-isomeride, by the action of  $PCl_5$  on hydrobenzoin (Zincke, A. 198, 129) and by the union of Cl with *s*-di-phenyl-ethylene (Laurent, B. J. 25, 620). Formed also from isohydrobenzoin and  $PCl_5$  (Ammann, A. 168, 67). Perhaps identical with the compound [180°] which is formed by heating benzylidene chloride with copper-powder at 100° (Onufrowicz, B. 17, 835).

**Properties.**—Silky needles (from alcohol), prisms (from toluene), or plates (O.). Sl. sol. boiling alcohol. May be sublimed. Alcoholic KOH forms *s*-di-phenyl-acetylene (tolane). AgOAc followed by KOH gives isohydrobenzoin.

(*β*)-Di-*exo*-chloro-*s*-di-phenyl-ethane  
 $C_6H_5CHClCHClC_6H_5$ . **Stilbene (*β*)-chloride.** [94°]. Formed as above. Thick tables. At 200° it is partially converted into the (*a*)-isomeride.

**Tri-chloro-*s*-di-phenyl-ethane**  $C_{12}H_7Cl_3$ . [85°]. From *s*-di-phenyl-ethylene and Cl (Laurent).

**Tri-chloro-*u*-di-phenyl-ethane**  $CCl_3CHPh_2$ . [64°]. From chloral, benzene, and  $H_2SO_4$  (Baeyer, B. 5, 1098). Small thin plates. Alcoholic KOH gives  $CPh_2CCl_3$ .

**Tri-chloro-*u*-di-phenyl-ethane**  
 $CH_2ClCH(C_6H_5)Cl_2$ . From di-chloro-di-ethyl-oxide  $CH_3CH_2CHClOEt$ , chloro-benzene, and  $H_2SO_4$  (Hepp, B. 7, 1419). On distillation it gives  $CH_2ClC(C_6H_5)Cl_2$ .

**Tetra-chloro-*s*-di-phenyl-ethane**  
 $C_6H_5CCl_2CCl_2C_6H_5$ . **Tolane tetra-chloride.** [163°]. **Formation.**—1. From benzil and  $PCl_5$  (Zinin, Z. 1868, 718).—2. A by-product in the preparation of benzotrichloride by chlorinating toluene (Liebermann & Homeyer, B. 12, 1971). 3. By heating benzotrichloride with copper-powder at 100° (Onufrowicz, B. 17, 833).—4. By heating benzotrichloride with benzene and copper-powder (Hanhart, B. 15, 901).

**Properties.**—Trimetric crystals; sol. benzene, hot alcohol, and ether. Gives a violet dye with dimethylaniline and  $ZnCl_2$ . Alcohol and zinc-dust gives (*a*) and (*β*) di-chloro-di-phenyl-ethylene.

**Penta-chloro-*u*-di-phenyl-ethane**  
 $CCl_3CH(C_6H_5)Cl_2$ . [106°]. S. (95 p.p. alcohol) 10. From chloral, chlorobenzene, and  $H_2SO_4$  (Zeidler, B. 7, 1181). Melted needles (from ether-alcohol). Alcoholic KOH gives  $C_6H_5CCl_3$ .

**CHLORO-DI-PHENYL-ETHYLENE**  
 $C_6H_5CClCH=C_6H_5$ . **Chloro-stilbene.** From stilbene di-chloride and alcoholic KOH (Zinin, A. 149, 875). Oil.

(*a*)-Di-chloro-*s*-di-phenyl-ethylene  
 $C_6H_5CClCHClC_6H_5$ . **Tolane-(*a*)-di-*s*-chloride.** [143°]. Formed, together with the (*β*)-modification, by the action of powdered zinc on an alcoholic solution of tetra-chloro-di-phenyl-ethane (Liebermann & Homeyer, B. 12, 1973; cf. Zinin, B. 4, 289); or of iron powder on an acetic acid solution of the same body (Lachowicz, B. 17, 1165). Formed also by passing Cl into a solution of *s*-di-phenyl-ethylene in chloro-

form. Both modifications are also formed by heating benzo-trichloride with copper-powder (Hannhart, B. 16, 899), and by heating *s*-di-phenyl-ethylene with  $\text{PCl}_5$  at  $180^\circ$  (Limpriehart a. Schwanert, B. 4, 379). Trimetric tables or prisms. Sl. sol. alcohol. Alcoholic KOH at  $180^\circ$  gives *s*-di-phenyl-acetylene (tolane).

( $\beta$ )-Di-chloro-*s*-di-phenyl-ethylene  $\text{C}_6\text{H}_4\text{Cl}_2\text{C}(\text{C}_6\text{H}_5)_2$ . Tolane- ( $\beta$ )-di-chloride. [ $63^\circ$ ]. Formed as above. Long needles. More soluble in alcohol than the ( $\alpha$ )-modification. The ( $\alpha$ ) and ( $\beta$ ) modifications can be partially changed into one another by distillation.

Di-chloro-*u*-di-phenyl-ethylene  $\text{C}_6\text{H}_4\text{Cl}_2\text{C}(\text{C}_6\text{H}_5)_2$ . [ $80^\circ$ ]. Formed by passing Cl into *u*-di-phenyl-ethylene and distilling the resulting  $\text{CCl}_4\text{C}_6\text{H}_4\text{Cl}_2$  (Hepp). Formed also from  $\text{CCl}_4\text{CHPh}_2$  by boiling with alcoholic KOH (Baeyer, B. 6, 223). Monoclinic prisms (from alcohol).

Di-chloro-*d*-di-phenyl-ethylene  $\text{C}_6\text{H}_4\text{Cl}_2\text{CH}(\text{C}_6\text{H}_5)_2$ . [ $170^\circ$ ]. Formed by passing Cl in excess into melted diphenyl (Kade, J. pr. [3] 19, 466). Needles or plates (from alcohol).

Di-chloro-*u*-di-phenyl-ethylene  $\text{JH}_2\text{C}(\text{C}_6\text{H}_4\text{Cl})_2$ . [ $283^\circ$ ]. Formed by distilling  $\text{CH}_2\text{ClCH}(\text{C}_6\text{H}_4\text{Cl})_2$  (Hepp, B. 7, 1419).

Tri-chloro-*s*-di-phenyl-ethylene  $\text{C}_6\text{H}_4\text{Cl}_3$ . Two modifications are formed by treating *s*-di-phenyl-acetylene (tolane) with  $\text{PCl}_5$  (Limpriehart a. Schwanert, B. 4, 379).

( $\alpha$ )-Modification: [ $137^\circ$ - $145^\circ$ ]; needles.

( $\beta$ )-Modification: [ $150^\circ$ ]; prisms.

Tetra-chloro-di-phenyl-ethylene  $\text{OCl}_2\text{C}(\text{C}_6\text{H}_4\text{Cl})_2$ . [ $80^\circ$ ]. From  $\text{CCl}_4\text{CH}(\text{C}_6\text{H}_4\text{Cl})_2$  and alcoholic KOH (Zeidler, B. 7, 1181).

TRI-CHLORO-DI-PHENYL-ETHYLIDENE DIAMINE  $\text{C}_6\text{H}_4\text{N}_3\text{Cl}_3$  i.e.  $\text{OCl}_2\text{CH}(\text{NHC}_6\text{H}_5)_2$ . [ $101^\circ$ ]. Formed by the action of aniline on chloral (Wallach, B. 5, 251; A. 173, 277). Tabular crystals (from alcohol). Insol. water. Decomposes at  $160^\circ$ . Boiling with alkalis forms phenyl carbamine. — $\text{B}'\text{H}_2\text{PtCl}_4$  (Amato, B. 9, 198).

DI-CHLORO-DI-PHENYL-GUANIDINE  $\text{C}_6\text{H}_4\text{Cl}_2\text{N}_3$  i.e.  $\text{NH}_2\text{C}(\text{NHC}_6\text{H}_4\text{Cl})_2$ . From aqueous di-phenyl-guanidine hydrochloride and Cl (Hofmann, A. 67, 147). Laminæ (from alcohol). — $\text{B}'\text{H}_2\text{PtCl}_4$ .

Di-chloro-di-phenyl-guanidine  $\text{NH}_2\text{C}(\text{NHC}_6\text{H}_4\text{Cl})_2$ . [ $141^\circ$ ]. From di-chloro-di-phenyl-thio-urea,  $\text{PbO}$ , and  $\text{NH}_3$  (Losanitsch, Bl. [3] 82, 170). Needles. Perhaps identical with the preceding.

Tri-*p*-chloro-tri-phenyl-guanidine  $\text{C}_6\text{H}_3\text{Cl}_3\text{N}_3$  i.e.  $\text{C}_6\text{H}_2\text{Cl}_3\text{N}_3\text{C}(\text{NHC}_6\text{H}_2\text{Cl}_3)_2$ . Formed by adding iodine to an alcoholic solution of di-chloro-di-phenyl-thio-urea  $\text{CS}(\text{NH}_2\text{C}_6\text{H}_4\text{Cl})_2$  (Beilstein a. Kurbatoff, A. 176, 51). Slender needles (from  $\text{CS}_2$ ). — $\text{B}'\text{H}_2\text{Cl}$ . — $\text{B}'\text{H}_2\text{I}$ : [ $255^\circ$ ]. — $\text{B}'\text{H}_2\text{SO}_4$ .

CHLORO-DI-PHENYL-KETONE v. CHLORO-BENZOPHENONE.

CHLORO-PHENYL MERCAPTAN  $\text{C}_6\text{H}_4\text{ClSH}$ . [ $54^\circ$ ]. From chloro-benzene sulphonic chloride, zinc, and dilute  $\text{H}_2\text{SO}_4$  (Otto, A. 148, 109). Four-sided trimetric tables (from alcohol). — $(\text{C}_6\text{H}_4\text{ClS})_2\text{Pb}$ : yellow pp.

*p*-CHLORO-PHENYL MERCAPTURIC ACID  $\text{C}_6\text{H}_4\text{ClNSO}_2$  i.e.  $\text{CH}_2\text{CO.NHClC}_6\text{H}_4(\text{S.C}_6\text{H}_4\text{Cl})\text{CO}_2\text{H}$ . [ $154^\circ$ ].

Found in the urine of a dog after it had taken chloro-benzene (Jaffé, B. 12, 1092). Colourless leaflets or tables. V. sl. sol. ether, v. sol. alcohol.

$\beta$ -CHLORO- $\beta$ -PHENYL-METHACRYLIC ACID  $\text{C}_6\text{H}_4\text{H}_2\text{ClO}_2$  i.e.  $\text{C}_6\text{H}_4\text{Cl.CCl.CMe.CO}_2\text{H}$ . [ $116^\circ$ ]. From methyl-benzoyl-acetic ether,  $\text{PCl}_5$ , and  $\text{PCl}_5$  (Perkin, jun., a. Calman, C. J. 49, 159). Needles, v. sol. alcohol, ether, benzene, and  $\text{HOAc}$ , m. sol. cold light petroleum. — $\text{Ag}^+$ .

CHLORO-DI-PHENYL-METHANE  $(\text{C}_6\text{H}_5)_2\text{CHCl}$ . Di-phenyl-carbinyl chloride. [ $14^\circ$ ]. From di-phenyl-carbinol and  $\text{HCl}$  (Engler a. Bethge, B. 7, 1128). Decomposed by heat into  $\text{HCl}$ , tetra-phenyl-ethylene, and tetra-phenyl-ethane (Anschütz, A. 235, 220).

Di-chloro-di-phenyl-methane  $(\text{C}_6\text{H}_5)_2\text{CCl}_2$ . Benzophenone chloride. [ $305^\circ$  i.v.]. S.G.  $d_{20}^{20} = 1.235$ . From benzophenone and  $\text{PCl}_5$  (Behr, B. 3, 752). Liquid. Decomposed by distillation. Warm water reconverts it into benzophenone.  $\text{KHS}$  gives  $(\text{C}_6\text{H}_5)_2\text{CS}$ . Heating with silver forms  $\text{Ph}_2\text{C.CPh}_2$ . Aniline forms  $\text{Ph.C.NPh}$ . Dimethyl-aniline gives  $\text{Ph}_2\text{CH.C}_6\text{H}_4\text{NMe}_2$  (Pauly, A. 187, 198).

Chloro-tri-phenyl-methane  $(\text{C}_6\text{H}_5)_3\text{CCl}$ . Tri-phenyl carbinyl chloride. [ $105^\circ$ - $115^\circ$ ]. From tri-phenyl-carbinol and  $\text{PCl}_5$  (Hemilian, B. 7, 1207). Formed also by the action of benzene on  $\text{CCl}_4$  in presence of  $\text{AlCl}_3$  (Friedel a. Crafts, A. Ch. [6] 1, 502). At  $250^\circ$  it gives  $\text{HCl}$ , tri-phenyl-methane, and  $(\text{C}_6\text{H}_5)_3\text{C}(\text{C}_6\text{H}_5)_2$  (Hemilian,

B. 11, 837). Hot water forms tri-phenyl-carbinol.

DI-CHLORO-TRI-PHENYL-METHANE CARBOXYLIC ACID  $(\text{C}_6\text{H}_5)_3\text{CHCl}_2\text{CO}_2\text{H}$ . [ $206^\circ$ ]. From di-chloro-di-phenyl-phthalide and boiling alcoholic  $\text{NaOH}$ ; the resulting  $(\text{C}_6\text{H}_5)_3\text{C}(\text{OH})\text{C}_6\text{H}_4\text{CO}_2\text{H}$  being reduced with zinc-dust and aqueous  $\text{NaOH}$  (Baeyer, A. 202, 84). Six-sided tables (from alcohol).  $\text{CrO}_3$  gives di-chloro-phenyl-oxanthranol.

Tetra-chloro-di-phenyl-methane carboxylic acid v. Tetra-chloro-*o*-benzyl-benzoic acid.

DI-CHLORO-DI-PHENYL-METHANE SULFONIC CHLORIDE  $\text{C}_6\text{H}_4\text{SO}_2\text{Cl}_2$  i.e.  $\text{CCl}_2(\text{C}_6\text{H}_4\text{SO}_2\text{Cl})_2$ . [ $129^\circ$ ]. From  $\text{CO}(\text{C}_6\text{H}_4\text{SO}_2\text{Cl})_2$  and  $\text{PCl}_5$  (Bockmann, B. 8, 992). Amorphous; sl. sol. alcohol.

TETRA-CHLORO-DI-PHENYL-METHYLAMINE  $\text{C}_6\text{H}_4\text{NCl}_4$  i.e.  $(\text{C}_6\text{H}_4\text{Cl})_2\text{NMe}_2$ . [ $97^\circ$ ]. Formed by passing Cl into a solution of  $\text{NPh}_2\text{Me}$  in  $\text{HOAc}$  (Gnehm, B. 8, 1040). Prisms.

CHLORO-PHENYL-METHYL-KETONE v. CHLORO-ACETOPHENONE.

DI-CHLORO-PHENYL-OXAMIC ACID  $\text{C}_6\text{H}_4\text{Cl}_2\text{NH.CO.CO}_2\text{H}$ . [ $122^\circ$ ]. S.  $d_{20}^{20}$  at  $25^\circ$ . Prepared by boiling tetra-chloro-oxanilide (4 gr.), alcohol (125 cc.) and  $\text{KHO}$  (5 gr.) for 10 minutes (Dyer a. Mixer, Am. 8, 854). White fibres. Sol. alcohol and ether.  $\text{KHO}$  solution gives di-chloro-aniline [ $63^\circ$ ].

Salts. — $\text{KA}^+$ : white hair-like fibres.

TETRA-CHLORO-DI-PHENYL-OXAMIDE  $\text{C}_6\text{H}_4\text{Cl}_2(\text{NH.C}_6\text{H}_4\text{Cl})_2$ . [ $1:2:4$ ]. Tetra-chloro-oxanilide. [c.  $255^\circ$ ]. From oxanilide by chlorination in  $\text{HOAc}$  (Dyer a. Mixer, Am. 8, 849). White fibres.

## DI-CHLORO-PHENYL-OXANTHRANOL

$C_{12}H_{11}Cl_2O$ , i.e.  $CO \langle \begin{smallmatrix} C_6H_4 \\ C_6H_4 \end{smallmatrix} \rangle C(OH).C_6H_4Cl$ . Phenol-phthalidein-chloride. [156°]. From di-oxy-phenyl-oxanthranol (phenol-*p*-phthalidein) and  $PCl_5$  at 120° (Baeyer, A. 202, 100). Silky needles (from alcohol).

## CHLORO-PHENYL-PHOSPHORIC ACID

$C_6H_5ClPO$ , i.e.  $C_6H_5ClO.PO(OH)_2$ . [81°]. Formed together with *p*-di-chloro-benzene by treatment of phenol *p*-sulphonic acid and  $PCl_5$ ; the resulting  $C_6H_5ClO.POCl$  being decomposed by water (Kekulé, B. 5, 877; 6, 944).—BaA'.

Chloride  $C_6H_5ClO.POCl$ . (265°).

*p*-CHLOROPHENYL PHTHALIMIDE

$O=C \begin{smallmatrix} \diagup \\ \diagdown \end{smallmatrix} \begin{smallmatrix} C_6H_4 \\ C_6H_4 \end{smallmatrix} \begin{smallmatrix} \diagdown \\ \diagup \end{smallmatrix} O$  [194°–195° uncor.]. Pre-  
 $O=N.C_6H_4Cl$

pared by heating *p*-chloro-aniline with phthalic anhydride (Gabriel, B. 11, 2260). Long fine needles. Sol. hot alcohol,  $C_6H_6$ , and acetic acid.

*o*-CHLORO-*o*-PHENYL-PROPIONIC ACID

$C_9H_7ClO_2$ , i.e.  $CH_2ClCHPh.CO_2H$ . Chloro-hydro-atropic acid [73°]. From atrolactic acid and HCl in the cold (Merling, A. 209, 19). Small prisms, m. sol. hot water, sl. sol. cold water. Volatile with steam. Attacks the mucous membrane. Decomposes at 110°. Boiling alkaline carbonates form no styrene.

*o*-Chloro-*o*-phenyl-propionic acid

$CH_2ClCHPh.CO_2H$ . Chloro-hydro-atropic acid. [89°]. Possibly identical with the preceding. Prepared by the action of HCl on the cyanhydrin obtained from acetophenone and HCN (Spiegel, B. 14, 235). From tropic acid and  $PCl_5$  followed by water (Ladenburg, A. 217, 77). Formed also by the union of atropic acid with fuming HCl at 100° (Merling, A. 209, 3). Colourless prisms. Sol. alcohol, ether, and benzene, sl. sol. water and ligroin. On boiling with aqueous NaOH it gives atropic acid. On heating with  $Na_2CO_3$  solution to 130° tropic acid is formed. Boiling aqueous  $Na_2CO_3$  forms tropic acid and a little styrene.

*o*-Chloro-*o*-phenyl-propionic acid

$C_9H_7ClO_2$ , i.e.  $CH_2ClCHPh.CO_2H$ . *o*-Chloro-hydrocinnamic acid. [97°]. Needles or plates. Formed by reduction of *o*-chloro-cinnamic acid with HI and P (Gabriel & Herzberg, B. 16, 2037).

*m*-Chloro-*o*-phenyl-propionic acid

$C_9H_7ClO_2$ , i.e.  $CH_2ClCHPh.CO_2H$ . *m*-Chloro-hydrocinnamic acid. [78°]. White easily soluble plates. Formed by reduction of *m*-chloro-cinnamic acid with HI and P (G. & H.).

*p*-Chloro-phenyl-propionic acid.

$C_9H_7ClO_2$ , i.e.  $CH_2ClCHPh.CO_2H$ . *p*-Chloro-hydrocinnamic acid [124°]. Formed by reduction of *p*-chloro-cinnamic acid (G. & H.).

*o*-Chloro-*o*-phenyl-propionic acid

$C_9H_7ClCHCl.CO_2H$ . [126°]. From *o*-oxy-*o*-phenyl-propionic acid and fuming HCl (Glaser, A. 147, 95). Very slowly formed by combination of cinnamic acid with HCl in conc. aqueous solution (Erlenmeyer, B. 14, 1867). Laminæ. Split up by heat into HCl and cinnamic acid; and by aqueous  $Na_2CO_3$  into  $CO_2$ , HCl, and styrene.

*o*-Di-chloro-*o*-phenyl-propionic acid

$C_9H_5Cl_2CHCl.CO_2H$ . [164°]. White plates.

Formed by leading Cl into a  $CS_2$  solution of cinnamic acid. With aqueous  $Na_2CO_3$  it gives *o*-chloro-styrene (Erlenmeyer, B. 14, 1867).

## (Py. 1)-CHLORO-(Py. 2)-PHENYL-ISOQUIN.

$C_{18}H_{15}ClN$  i.e.  $C_6H_5 \begin{smallmatrix} \diagup \\ \diagdown \end{smallmatrix} \begin{smallmatrix} CCl:CPH \\ CH:N \end{smallmatrix} \begin{smallmatrix} \diagdown \\ \diagup \end{smallmatrix} C_6H_5$ . [70°].

Obtained by reduction of (Py. 1:4)-di-chloro-(Py. 2)-phenyl-isoquinoline with HI and P. Glistening pillars. Salts.—B'HCl: small thick crystals.—B' $H_2Cl.PtCl_5$ : orange yellow needles (Gabriel, B. 18, 3475).

## (Py. 4)-Chloro-(Py. 2)-phenyl-isoquinoline

$C_{18}H_{15}ClN$  i.e.  $C_6H_5 \begin{smallmatrix} \diagup \\ \diagdown \end{smallmatrix} \begin{smallmatrix} CH:CPH \\ CCl:N \end{smallmatrix} \begin{smallmatrix} \diagdown \\ \diagup \end{smallmatrix} C_6H_5$ . [78°]. Prepared

by boiling (Py. 4)-oxy-(Py. 2)-phenyl-isoquinoline (isobenzalphthalimidine) with  $POCl_3$  (2 pts.). It is also formed by heating the same compound with  $PCl_5$  at 100°–130°. Flat pointed needles. Sol. alcohol, v. sol. benzene, ether, petroleum-spirit, chloroform, and  $CS_2$ , insol. water. Heated with HI and P at 170° it is reduced to phenyl-isoquinoline (Gabriel, B. 18, 3473).

## (Py. 1:4)-Di-chloro-(Py. 2)-phenyl-isoquinol.

$C_{18}H_{13}Cl_2N$  i.e.  $C_6H_5 \begin{smallmatrix} \diagup \\ \diagdown \end{smallmatrix} \begin{smallmatrix} CCl:CPH \\ CCl:N \end{smallmatrix} \begin{smallmatrix} \diagdown \\ \diagup \end{smallmatrix} C_6H_5$ . [163°]. Ob-

tained by heating (Py. 4)-oxy-(Py. 2)-phenyl-isoquinoline (isobenzalphthalimidine) with  $PCl_5$  at 100°. By boiling with HI and P it is reduced to (Py. 1)-chloro-(Py. 2)-phenyl-isoquinoline [70°] (Gabriel, B. 18, 3473).

## TRI-CHLORO-TRI-PHENYL-ROSANILINE

$C_{18}H_9Cl_3N$ , i.e.  $CH_2Cl.NH.C_6H_4.Ma.C(OH)(C_6H_5)_3$ . Theo-, *m*- and *p*-compounds are formed by heating rosaniline with *o*-, *m*-, or *p*-chloraniline in presence of benzoic acid. They dye silk various shades of bluish violet (Heumann & Heidberg, B. 19, 1992).

## DI-CHLORO-DI-PHENYL SULPHIDE

$(C_6H_4Cl)_2S$ . [89°]. From 'thio-aniline'  $S(C_6H_4NH_2)_2$  by displacement of  $NH_2$  by Cl through the diazo-reaction (Krafft, B. 7, 1165).

Di-chloro-di-phenyl di-sulphide  $(C_6H_4Cl)_2S_2$ . [71°]. From  $C_6H_5Cl.SH$  and  $HNO_3$  (§. G. 1:12) (Otto, A. 143, 111). Tables. Zinc and dilute  $H_2SO_4$  reconvert it into chloro-phenyl mercaptan.

## CHLORO-DI-PHENYL SULPHONE

$C_6H_5.SO_2.C_6H_5Cl$ . [92°]. (889°). From benzene sulphonie chloride, benzene, and  $AlCl_3$ ; the yield is 87 p.c. of the theoretical (Beckurts & Otto, B. 11, 2067; 19, 2418). Leaflets. Insol. water; v. sol. hot alcohol.

Di-*o*-chloro-di-phenyl sulphone  $(C_6H_4Cl)_2SO_2$ . [174°]. (860°). Formed\* in sulphonating *o*-di-chloro-benzene (Friedel & Crafts, A. 61, 10, 414). Crystals.

Di-chloro-di-phenyl-sulphone  $C_6H_4Cl.SO_2$  (above 800°). Formed by chlorinating di-phenyl-sulphone in diffused daylight at 100° in presence of iodine (Otto & Gruber, A. 149, 180). Oil.

Di-*p*-chloro-di-phenyl-sulphone  $(C_6H_4Cl)_2SO_2$ . [141°] (0.); [147°] (B. & O.). From chlorobenzene and  $SO_2$  (Otto, A. 145, 28). Also from chloro-benzene and  $ClSO_3H$  (Beckurts & Otto, B. 11, 2065). Plates.  $H_2SO_4$  at 150° gives chloro-benzene sulphonie acid. Sodium amalgam in alcoholic solution gives benzene, chlorobenzene sulphonie acid, and benzene sulphonie acid.

**CHLORO-PHENYL-THIO-CARBAMIC ETHER**  $C_6H_4Cl.NHCS.OEt$ . [103°]. Formed by adding iodine to an alcoholic solution of di-chloro-di-phenyl-thio-urea (Beilstein a. Kurbatoff, A. 176, 52). Needles.

**o-CHLORO-PHENYL-THIO-CARBIMIDE**  $C_6H_4(Cl).NCS$  [1:2]. [45°]. (250°). Crystalline solid. Prepared by the action of  $P_2O_5$  on the corresponding urea derived from o-chloro-nitrobenzene (Hofmann, B. 13, 14). An isomeride is chloro-methenyl-amido-phenyl-mercaptan

**m-Chloro-phenyl-thiocarbimide**  $C_6H_4(Cl).NCS$  [1:3]. (250°). Prepared by the action of  $P_2O_5$  on the corresponding urea [122°] obtained from m-chloro-aniline and  $CS_2$  (Hofmann, B. 13, 13). Liquid.

**p-Chloro-phenyl-thio-carbimide**  $C_6H_4(Cl).NCS$  [1:4]. [45°]. (250°). Crystalline solid. Prepared by the action of  $CS_2$  on p-chloro-aniline and decomposition of the resulting di-chloro-phenyl-urea (Hofmann, B. 13, 13; Beilstein a. Kurbatoff, A. 176, 51; Losanitsch, B. 5, 156).

**DI-o-CHLORO-DI-PHENYL-THIO-UREA**  $C_6H_4(Cl)_2.N_2S$  i.e.  $CS(NH.C_6H_4Cl)_2$ . [146°]. From o-chloro-aniline and  $CS_2$  (Hofmann, B. 13, 14).

**Di-m-chloro-di-phenyl-thio-urea** [122°] (H.).

**Di-p-chloro-di-phenyl-thio-urea** [168°]. S. (in  $CS_2$ ) 0.264 at 13.7° (Beilstein, A. 176, 47). From p-chloro-aniline,  $CS_2$ , and alcohol (Losanitsch, B. 5, 156; Bt. [2] 32, 170). Iodine acting on its alcoholic solution forms di-chloro-di-phenyl-urea, tri-chloro-tri-phenyl-guanidine, chloro-phenyl-thio-carbimide, and chloro-phenyl-carbamic ether.

**TRI-CHLORO-PHENYL-TOLYL-ETHANE CARBOXYLIC ACID**  $C_6H_3Cl_3.C_6H_4.CO_2H$  i.e.  $CH_3.C_6H_4.CH(CCl_3).C_6H_3Cl_3.CO_2H$ . [174°]. From  $(CH_3.C_6H_4).CH.CCl_3$  and chromic mixture (O. Fischer, B. 7, 1192). Tables (from alcohol). Alkalis give  $CH_3.C_6H_4.C(CCl_3).C_6H_3Cl_3.CO_2H$ .

**DI-CHLORO-PHENYL-TOLYL-KETONE CARBOXYLIC ACID** v. DI-CHLORO-TOLYL-BENZOIC ACID.

**o-CHLORO-PHENYL-TOLYL-METHANE**  $CH_3.Cl.C_6H_3.CH_2.C_6H_4$ . A mixture of the o- and p- varieties of this body is one of the products of the action of benzyl chloride on water at a high temperature, the reaction being as follows:  $2C_6H_5.CH_2Cl = HCl + CH_3.Cl.C_6H_4.CH_2.C_6H_5$ . The mixture on oxidation gives o- and p-benzoyl-benzoic acid (Senff, A. 220, 249).

**DI-p-CHLORO-DI-PHENYL-UREA**  $(C_6H_4.Cl.NH).CO$ . A secondary product in the preparation of p-chloro-phenyl thiocarbimide by the action of  $P_2O_5$  or of iodine on the corresponding thio-urea (Beilstein a. Kurbatoff, A. 176, 46). Long needles (from HOAc). Volatilises at 270°.

**TRI-CHLORO-PHLOROGLUCIN**  $C_6H_3Cl_3O_2$ . [129°]. Formed by passing chlorine into a solution of phloroglucin in HOAc until the liquid ceases to give a red colour with wood (Webster, C. J. 47, 423; Hazura a. Benedikt, M. 6, 706). Slender needles (containing 3aq). Dilute  $HNO_3$  gives oxalic acid. Chlorine, in presence of  $CCl_4$ , gives chlorinated acetic aldehyde and tri-chloro-acetic acid. When chlorine is passed into an aqueous solution of phloroglucin there is formed di-chloro-acetic acid.

**Hexa-Hydrate**  $C_6H_3Cl_3O_2$ . [125°]. From hexa-bromo-phloroglucin dibromide, tin, and HCl (H. a. B.). Needles (containing 3aq).

**CHLORO-PHLORONE** v. CHLOROXYLOQUINONE.

**o-CHLORO-PHTHALIC ACID**  $C_6H_3Cl_2O_4$  i.e.  $C_6H_3Cl_2(CO_2H)_2$  [4:2:1]. [148°] (C. a. D.; G. a. R.; C. a. M.); [130°] (I.); [c. 194°] (K.).

**Formation.**—1. By oxidation of (e)-di-chloro-naphthalene [135°] (Alén, Bt. [2] 86, 434), of chloro-(β)-naphthol (Claus a. Dehne, B. 15, 320), of the two chloro-toluic acids [130°] and [166°] (Krüger, B. 18, 1758), of (β)-di-chloro-(α)-naphthoquinone (Claus a. Müller, B. 18, 3076), and of chloro-di-ethyl-benzene (Istrati, A. Ch. [6] 6, 413).—2. By saponifying the chloride which may be formed by the action of  $PCl_5$  on the tri-chloride of sulpho-phthalic acid  $O < \begin{array}{c} CCl_2 \\ CO \end{array} > C_6H_3.SO_2Cl$  (Rée, A. 233, 236).

**Properties.**—Small needles. V. sol. water and alcohol; m. sol. dilute HCl, chloroform, and  $CS_2$ , sl. sol. benzene, insol. ligroin. With resorcin it gives a chloro-fluorescein.

**Salts.**— $K_2A''$ : large needles, v. sol. water.— $BaA''$ : amorphous; sl. sol. water.— $BaH_2A''_2$ : small needles, sl. sol. water.— $CaA''$ : scales, sl. sol. water.— $Ag_2A''$ : white pp.

**Anhydride**  $C_6H_3Cl_2 < \begin{array}{c} CO \\ CO \end{array} > O$ . [95°] (C. a. D.); [97°] (G. a. R.; K.); [114°] (I.). Formed by heating the acid. Triclinic needles (by sublimation).

**Methyl ether**  $MeA''$ . [37°]. Needles.

**Ethyl ether**  $EtA''$ . [−20°]. (c. 303°) (Graebe a. Rée, C. J. 49, 528).

**Chloride**  $C_6H_3Cl_2 < \begin{array}{c} CCl_2 \\ CO \end{array} > O$ . (276° uncor.). Liquid.

**Imide**  $C_6H_3Cl_2 < \begin{array}{c} CO \\ CO \end{array} > NH$ . [211°]. From the anhydride and  $NH_3$  (Rée, A. 233, 236).

**c-Chloro-phthalic acid**  $C_6H_4Cl(CO_2H)_2$  [3:2:1]. [184°] (G.); [181°] (K.). S. 2:16 at 14°.

**Formation.**—1. By oxidation of chloro-toluic acid [164°] with  $KMnO_4$  (Krüger, B. 18, 1758).—2. By oxidation of (γ)-di-chloro-naphthalene [107°] with  $CrO_3$  in  $HOAc$  (Guarreschi, G. 17, 121; B. 19, 134).

**Properties.**—Long needles; sl. sol. cold, v. sol. hot, water; v. sol. alcohol and ether. Gives the anhydride on melting. Heated with phenol and conc.  $H_2SO_4$  it gives a phthalein which dissolves in alkalis forming a violet solution.

**Salts.**— $BaA''$  aq: long silky needles, v. sol. cold, sl. sol. hot, water. By boiling with water it is converted into an insoluble crystalline powder  $BaA''$  aq.— $Ag_2A''$ : crystalline pp.

**Anhydride**  $C_6H_4Cl < \begin{array}{c} CO \\ CO \end{array} > O$ . [123°].

Needles (by sublimation). By chlorination of phthalic acid Auerbach (J. 1880, 852) obtained an (impure?) phthalic acid [150°] whose anhydride melted at 149°.

**Di-chloro-phthalic acid**  $C_6H_2Cl_2(CO_2H)_2$ . Formed by oxidation of the tri-chloro-naphthalene [90°] (from (β)-naphthol-(β)-di-sulphonate and  $PCl_5$ ), by heating with dilute  $HNO_3$  (S.G. 1:16) at 210°. Syrup. Could not be obtained crystallised although apparently pure.

**Salts.**—The Na and K salts are excessively

phthalimide, tin, and HCl (Weyer, A. 258, 850)

Crystals (from chloroform). Gives a nitroso-derivative.

**TETRACHLORO-DIPHETHALYL**  $C_{12}H_2Cl_4O_2$

Formed by the condensation of tetra-chloro-phthalic anhydride without the use of sodium acetate (Graebe & Guye, A. 233, 245). Brownish yellow powder; insol. alcohol, glacial acetic acid and toluene; sol. chloroform, aniline and phenol.

**CHLOROPHYLL**—the peculiar substance to which the green colour of leaves and other parts of plants is due—was first examined by Pelletier and Caventou, who called it *chlorophyll*. From the chemist's point of view it is simply an organic colouring matter, like indigo or alizarin.

It is important to bear this in mind, since much confusion and misunderstanding have arisen from the term chlorophyll having been applied to distinct things. Some chemists understand by chlorophyll the sum of the coloured constituents of leaves insoluble in water, and it has accordingly been proposed to call that constituent the colour of which inclines more to blue, *Kyanophyll*, while that constituent or group of constituents which gives solutions of a yellow or greenish-yellow tint should be named *Xanthophyll*. In works on vegetable physiology the term chlorophyll is sometimes applied to the complex of substances contained in living green cells, which take part in the process of assimilation and of which the colouring matter constitutes a portion, and chemists, following this example in giving a name to the whole which should have been confined to one part, have been led to ascribe to chlorophyll properties which no mere chemical substance can possibly possess. In order to avoid confusion it should therefore be understood that in using the term chlorophyll we mean simply the substance—or it may be mixture of substances—to which the pure green colour of ordinary healthy leaves and of other vegetable organs, such as unripe fruit, is due. The appearance in leaves of any colour other than green, such as red, yellow, or purple, would indicate the presence of some substance accompanying the chlorophyll and disguising its colour or even replacing it entirely.

Chlorophyll is invariably present in vegetable cells in which the process of assimilation, i. e. the formation of organic matter from  $CO_2$  and  $H_2O$  with elimination of  $O$ , is going on. Parasitic and other plants, such as fungi, which obtain their nutriment ready-formed from other organisms or from decaying organic matter, and do not decompose  $CO_2$  in the same way as the majority of plants, contain no chlorophyll. Plants or shoots grown in the dark from seeds or tubers are also devoid of chlorophyll; they grow at the expense of the matter stored up in the seed or tuber, and when this is exhausted they die. The appearance of chlorophyll in etiolated plants on exposure to light indicates the commencement of assimilation. It is certain, therefore, that chlorophyll plays some part in the process of assimilation, and that its presence is essential, but how it acts in assisting the process is unknown, its physical and

chemical properties, so far as they are known to us, affording no certain clue to the solution of the problem. In the green cells of plants the chlorophyll is found associated with the protoplasmic constituent from which it may be easily separated by treatment with alcohol or ether. The green corpuscles seen in vegetable cells are in fact masses of albuminoid and other matters, permeated and tinged by chlorophyll, which is probably contained in a state of solution in the cell and not as a solid.

*Physical and chemical properties of chlorophyll.*—Considering the great importance of chlorophyll in relation to the process of assimilation in plants, it can hardly be a matter for surprise that it should very frequently have been examined. The literature of chlorophyll is very extensive, and comprises memoirs by physicists, chemists, and physiologists, some of them men of great eminence in their respective branches of science. Nevertheless, our knowledge of its properties, physical and chemical, is very scanty. The imperfect state of our knowledge of the subject is due to several causes. In the first place the quantity of chlorophyll contained in an extract of leaves, though the latter may be intensely coloured, is extremely small; secondly, chlorophyll is associated in the plant with large quantities of other substances, colouring matters, resins, fats, &c., which accompany it on extraction with ordinary solvents, and from which it cannot easily be separated; thirdly, it is a substance which is very apt to undergo change, so that during any process of purification to which it may be submitted, it will almost certainly be more or less altered; fourthly, chlorophyll, like most substances which play an important part in the vegetable or animal economy, is certainly amorphous, and the freedom from impurity of any specimen must therefore always be more or less doubtful. Some observers have described bodies which they have held to be crystallised chlorophyll, but the writer is of opinion that these were in all cases products of decomposition derived from chlorophyll. Chlorophyll contains nitrogen in addition to carbon, hydrogen and oxygen, but the percentage is certainly not large. It has been supposed to contain iron like the hæmoglobin of blood; after incineration a minute quantity of ferric oxide is indeed always found in the ash, but whether this is derived from chlorophyll, or from some substance or substances accompanying it, is uncertain. The ash also contains calcium and magnesium phosphates, but of these again it cannot with certainty be said that they are constituents of chlorophyll itself. Chlorophyll may, be described as a neutral body, like indigo, having the properties, neither of an acid nor a base; in constitution it may resemble the fats or the lecithins, as suggested by Hoppe-Seyler. Though not itself a glucoside, it is always found associated with a body having the characteristics peculiar to that class, as was first pointed out by the writer.

Chlorophyll is insoluble in water, but soluble in alcohol, ether, carbon disulphide and ethereal oils.

These solutions show a lively green colour of great intensity, accompanied by a marked

red fluorescence. The solutions show an absorption spectrum which is quite characteristic, and must therefore be shortly described. A solution of chlorophyll made by extracting fresh green leaves with alcohol or ether is found, when very dark, to absorb nearly the whole spectrum, only a narrow strip of light at the extreme red end being visible. When the solution is made paler by the addition of more solvent, the green of the spectrum begins to appear, a faint absorption band showing itself about the middle. On still further diluting, other bands make their appearance in succession. When an average depth of colour is reached the following absorption bands are seen:—A very dark band beginning close to the line B and extending over C, followed by a second band between C and D which is much lighter, after which comes a third still paler one beyond D and close to the latter, lastly, a fourth band is seen partly on E which is usually the faintest of all, but is sometimes as dark as, and even darker than the third (see Fig. i.). Total obscuration begins about the line F. The four bands just described are usually marked with the numerals I–IV, in accordance with the notation employed by Ångström, and are seen so constantly and invariably, when proper precautions are taken to have a solution of unchanged chlorophyll of average strength, as to constitute a certain test for chlorophyll, which may accordingly be defined as the substance which in solution shows this particular absorption spectrum. It should be mentioned that there is a considerable amount of obscuration throughout the whole spectrum of chlorophyll solutions, excepting only at the extreme red, so that the parts usually represented as white are in reality more or less darkened, and also that the bands, with the exception of band I, are not so sharply defined as the ordinary representations would lead one to suppose in consequence of the edges gradually shading off. Opinions differ as to whether the same absorption spectrum is seen when a green leaf is placed before the slit of a spectroscope, some observers maintaining that only band I. is discernible, while others say that all four bands can be made out, the only difference being that the bands are all shifted towards the red end, from which it has been inferred that in the plant chlorophyll exists in a state of solution, the solvent having a density greater than that of alcohol or ether. Returning to the solution of chlorophyll showing the spectrum just described, let us now see what takes place on further dilution. A beam of sunlight having been thrown on the slit of the spectroscope the solution is to be considerably diluted until it becomes quite pale. It will then be found that band I. having become narrower and paler has left the line C altogether and taken its place near B; band II. has become much narrower and paler, but remained in the same place, while bands III. and IV. have entirely disappeared. At the other end of the spectrum, however, two pale, ill-defined bands have made their appearance, one being situated between F and G, the other on G (see Fig. ii.). These bands are numbered V. and VI. Whether they belong to chlorophyll itself or to some other colouring matter accompanying it is uncertain, no one having as yet succeeded in

obtaining a solution of chlorophyll in which they are not seen, provided the solution is sufficiently dilute and is observed in sun-light. The writer is of opinion that the two bands belong to a yellow colouring matter (xanthophyll?) always accompanying chlorophyll, from which the latter cannot be separated. It is certain that all leaves contain a colouring matter, the chrysophyll of Hartsen (Bougarel's erythrophyll), which may be obtained in lustrous, orange-coloured crystals, and gives yellow solutions, showing two distinct absorption bands at the blue end—not exactly in the same position as those just referred to—but no trace of any band in the other parts of the spectrum; the bands V. and VI. may belong to a nearly allied substance.

The absorption bands of chlorophyll solutions were first described by Sir D. Brewster, who was also the first to observe the red fluorescence of these solutions. The bands were next examined by Stokes and Ångström, by the latter of whom they were also correctly figured. Many other observers have worked on the same field; among these the following may be named: Askénasy, Gerland and Rawenhoff, Hagenbach, Harting, Kraus, L. Liebermann, Lommel, A. Meyer, Micheli, Morot, Pringsheim, Russell and Lapraik, Sacchse, Simmler, Sorby and Wiesner. The memoirs of Hagenbach, Kraus, Lommel, Pringsheim, Russell and Sorby on the subject are especially worthy of study. It should be mentioned that some of the absorption spectra figured in memoirs on chlorophyll really belong to derivatives of the latter. Whenever in such figures band IV. appears rather dark and is followed by another dark band nearer the blue end, we may conclude that the observer has worked with a specimen of chlorophyll that has undergone some change.

*Products of decomposition of chlorophyll.*—A solution of chlorophyll inclosed in a sealed tube and kept in the dark retains its colour for any length of time, but in an open vessel, especially when exposed to light, the colour disappears rapidly, only a faint yellow tinge remaining; what is formed during this change, which is doubtless due to oxidation, is not known.

By the action of acids chlorophyll undergoes a marked change, which no one who has worked with the substance can have failed to observe. When to an alcoholic solution of chlorophyll a small quantity of sulphuric or hydrochloric acid is added, the colour of the solution changes at once from a bright green to a dull yellowish-green or olive. Examined in the usual manner the spectrum will be found entirely altered; bands I. and II. have become more distinct from the clearing up of the space between the two, band III. appears much paler, and band IV. much darker, than before. After the solution has stood for some time band IV. will be found to have greatly increased in intensity, while another dark band has made its appearance near the line F just in front of the part where total obscuration begins. This is what has, not very appropriately, been called the absorption spectrum of *acid chlorophyll*, and is due to the formation of products derived from chlorophyll by a process the nature of

which is not understood. That this process is not such a one as might admit of explanation by supposing chlorophyll to have the constitution of a salt, its acid constituent being expelled by the addition of a stronger acid, is proved by the fact that if alcoholic potash or soda be added in excess to a solution of chlorophyll which has been acted on by acids, the original bright green colour is not restored. To those conversant with the decomposition of complex organic substances, another explanation may suggest itself, viz. that the change is due to hydrolysis in presence of an acid, accompanied perhaps by a splitting up of the same kind as that which glucosides undergo when acted on by acids or ferments. Russell and Lapraik are of opinion that the change is a molecular, not a chemical one. Weak acids produce the same change as strong ones, but only after some time. On the addition of a comparatively large quantity of acetic acid to an alcoholic solution of chlorophyll, no change of colour is perceived at first, nor is the spectrum in any way altered, but on standing the colour slowly passes over to yellowish-green, and the same bands make their appearance as when a strong acid is employed. The same change frequently takes place when a solution of chlorophyll is left to stand in a loosely-stoppered bottle kept in the dark; in this case the effect is probably due to the presence of some substance, an ethereal oil for instance, which by oxidation yields an acid of some kind. Some leaves, such as those of the vine and virginian creeper, naturally contain much free acid which, on extraction of the leaves with alcohol, accompanies the chlorophyll and changes it after a short time.

In order to obtain the products derived from chlorophyll by the action of acids, fresh green leaves are extracted with boiling spirits of wine; the liquor after straining is allowed to stand, so that a portion of the fatty matter contained in it may be deposited, after which it is filtered and a current of hydrochloric acid gas is passed through it. By the action of the acid a dark brownish-green flocculent precipitate is formed, which after standing is filtered off and washed with alcohol. This precipitate contains two peculiar colouring matters, which Fremy named *phyllocyanin* and *phylloxanthin*, along with impurities of a fatty nature. The two colouring matters are separated by Fremy's method; the mixture is dissolved in ether, and the solution is shaken up with about a quarter its volume of concentrated  $\text{ClH}$ , whereupon it separates into two layers, an upper yellowish-green one containing phylloxanthin, and a lower bright-blue one containing phyllocyanin.

The phylloxanthin of the upper stratum is largely contaminated by fatty matter, from which it cannot easily be separated, but the phyllocyanin from the lower stratum can be purified and is obtained in microscopic crystals, which are generally opaque, but when very thin appear olive-coloured by transmitted light. The general properties of phyllocyanin have been described by the writer, but a few only of these can here be mentioned. Phyllocyanin is a body entirely *sui generis*, resembling no other natural colouring matter. It is insoluble in water and ligroin, but soluble in alcohol, ether,

acetic acid, chloroform, benzene, and carbon disulphide. The solutions show an absorption spectrum with five bands (see Fig. iii.). It dissolves in concentrated  $\text{ClH}$  and  $\text{SH}_2\text{O}$ , giving solutions of a bright blue colour, and is reprecipitated unchanged by water. It dissolves in alkaline lyes, but is entirely changed by the action of the alkali. Its most interesting property is that of yielding by the combined action of acids, chiefly organic acids, and metallic oxides, such as cupric, ferrous and zinc oxides, compounds, the solutions of which are bright green and closely resemble solutions of chlorophyll not only in colour but in other respects also.

Phyllocyanin is remarkable for its great stability; its solutions remain for a long time unchanged when exposed to light and air, whereas solutions of chlorophyll are rapidly bleached under the same circumstances. Phyllocyanin yields with alkalis and reducing agents products which show absorption spectra of great variety and beauty (see Figs. v. and vi.). Phylloxanthin resembles phyllocyanin in many of its properties, but is a less interesting substance. Its absorption spectrum shows only four bands (see Fig. iv.). It will be seen that when the two substances are present together in solution, the bands of phylloxanthin will be concealed by those of phyllocyanin.

On reading some of the older memoirs on chlorophyll, such as those of Berzelius, Mulder, and Fremy, it will be evident that the authors worked not with chlorophyll itself, but with products due to the action of acids on the latter. It is probable that the *chlorophyllan* of Hloppe-Seyler and the *hypochlorin* of Pringsheim are products belonging to the same class as phyllocyanin and phylloxanthin. According to Tschirch chlorophyllan is the first product of the action of acids on chlorophyll, and splits up into phyllocyanin and phylloxanthin when the action of acid is prolonged. This short account may serve to show that our knowledge of the derivatives of chlorophyll is still very defective.

*Chlorophyll in relation to plant life.*—There can be no doubt that the presence of chlorophyll is necessary during the process of assimilation by plants, but what part it plays in the process is unknown. It was at first supposed, considering how powerfully the more refrangible end of the spectrum is absorbed by solutions of chlorophyll, that it was especially the blue rays that effected the decomposition of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  within the cells. This idea was soon abandoned in favour of another theory, according to which it is the red rays that are more active than the others in promoting assimilation, they being also strongly absorbed by chlorophyll. The latest investigations make it probable that the yellow rays, which are the least absorbed of any, produce a more abundant evolution of  $\text{O}$ , and consequently a greater amount of decomposition of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  than either the red or blue rays. Pringsheim is of opinion that chlorophyll acts simply as a screen which absorbing the less refrangible rays, moderates the energetic heating and oxidising action of the latter during the process of assimilation. All that can be positively asserted with regard to this part of the subject is that the colour, i.e. the absorp-

live power of chlorophyll has something to do with its mode of action.

It has been thought, and we often find it stated in books, that chlorophyll has itself the power of absorbing  $\text{CO}_2$  and evolving  $\text{O}$ ; attempts have even been made to prove that this takes place in ordinary solutions of chlorophyll. This is, however, erroneous; it is certain that the complex which physiologists call the chlorophyll corpuscle, or simply chlorophyll, has the power of decomposing  $\text{CO}_2$  and  $\text{H}_2\text{O}$  with evolution of  $\text{O}$ , but that any such power resides in the colouring matter when dissociated from the other constituents of the complex must be incorrect, since it is opposed to all that we know of the chemical properties of organic substances.

List of the most important memoirs and works on chlorophyll:—

Ångström, *Ueb. d. grüne Farbe d. Pflanzen*, P. 93, 475; Askenasy, *Bot. Ztg.*, 1867, 225;

phyllfarbstoffe, Stuttgart, 1872; Kromeyer, *Zerlegung des Chlorophylls in einem blauen und einem gelben Farbstoff*, *Ar. Ph.* 155, 164; L. Liebermann, *Sitz. W.* 72, 599; Lommel, *Ueb. d. Verhalten d. Chlorophylls zum Licht*, P. 143, 568; Meyer, *Das Chlorophyllkorn*, Leipzig, 1883; Micheli, *Arch. d. Sc. de la bibl. univ. d. Genève*, Mai 1867; Morot, *Ann. des Sc. Nat.* 3rd ser. 13, 160; Mulder, *Ueber d. Chlorophyll*, *J. pr.* 33, 478; Pelletier et Caventou, *Sur la matière verte des feuilles*, *A. Ch.* 9, 194; Pfander, *A.* 115, 37; Pringsheim, *Untersuchungen üb. Lichtwirkung u. Chlorophyllfunction in d. Pflanzen*, Leipzig, 1881; Russell and Lapraik, *A Spectroscopic Study of Chlorophyll*, *C. J.* 41, 334; Sachsse, *Die Chem. u. Physiol. d. CHLORO-PICOLINE o. OHLORO-METHYL-PYRIDINE.

CHLORO-PICOLINIC ACID o. CHLORO-PIRIDINE CARBOXYLIC ACID.

CHLOROPICRIN o. TRI-CHLORO-NITRO-METHANE.

CHLOROPLATINATES o. PLATINATES UNTER PLATINUM.

CHLORO-PROPANE o. PROPYL CHLORIDES.

***αα*-Di-chloro-propane**  $C_3H_5Cl_2$ , *i.e.*  $CH_3CHClCH_2Cl$ . *Propylene chloride*. Mol. w. 118. (97° cor.). S.G.  $\frac{d}{4}$  1.684;  $\frac{d}{15}$  1.155 (F. a. S.);  $\frac{d}{15}$  1.166 (Linnemann, A. 161, 62).

**Formation.**—1. From chlorine and propylene (Cahours, A. 76, 283; Reynolds, A. 77, 124).—2. From chloro-iodo-propane and Cl (Friedel a. Silva, C. R. 76, 1596).—3. From propane and Cl (Schorlemmer, Pr. 17, 873; A. 150, 214).—4. Together with  $CH_3CCl_2CH_3$ , by chlorinating  $CH_3CHClCH_3$  in sunshine (Friedel a. Silva, Bl. [2] 16, 8).—5. From isopropyl chloride and ICl (Friedel a. Silva, C. R. 73, 1380).—6. From allyl chloride and conc. HCl at 100° (Reboul, A. Ch. [5] 14, 453).

**Reactions.**—1. Alcoholic KOH gives *α*-chloro-propylene  $CH_3CClCH_2$  (Friedel a. Silva, A. Ch. [4] 16, 849).—2. Water (20 vols.) at 220° gives propionic aldehyde and acetone. Water and PbO at 150° give propylene glycol (Eltekoff, B. 6, 558).—3. Conc. Hl at 150° gives isopropyl chloride.

***αα*-Di-chloro-propane**  $CH_3CH_2CHCl_2$ . *Propylidene chloride*. (86°). S.G.  $\frac{d}{15}$  1.143. Formed, together with chloro-propylene  $CH_3CHClCH_2Cl$ , by the action of  $PCl_5$  on propionic aldehyde (Reboul, A. Ch. [5] 14, 458). Alcoholic KOH gives  $CH_3CH_2CHCl_2$  (84°).

***αα*-Di-chloro-propane**  $CH_3CCl_2CH_3$ . *Chloroacetol. Methylchloracetol*. (70°). S.G.  $\frac{d}{15}$  1.0966;  $\frac{d}{15}$  1.0848 (Parkin, C. J. 45, 529);  $\frac{d}{15}$  1.827 (Linnemann, A. 161, 67). H.F.p. 42080. H.F.v. 40340 (Th.).

**Formation.**—1. From acetone and  $PCl_5$  (Friedel, A. 112, 238).—2. From isopropyl chloride and Cl (Friedel a. Silva, Z. 1871, 489).—3. From allylene and fuming HCl in the cold (Reboul, A. Ch. [5] 14, 453).

**Reactions.**—1. Alcoholic KOH forms *α*-chloro-propylene  $CH_3CClCH_2$  (24°).—2. AgOBz gives  $(CH_3)_2C(OBz)_2$ .—3. Water (8 vols.) at 170° gives acetone (Oppenheim, B. 2, 213).

***ββ*-Di-chloro-propane**  $CH_3CHClCH_2CH_2Cl$ . *Trimethylene chloride*. (119°). S.G.  $\frac{d}{15}$  1.201 (R.);  $\frac{d}{15}$  1.4896 (F.). From the corresponding dibromide and  $HgCl_2$  at 180° (Reboul, A. Ch. [5] 14, 453). Formed also from trimethylene glycol  $CH_2OHCH_2CH_2OH$  and HCl (Freund, M. 2, 638). Alcoholic KOH gives allyl chloride.

***ααβ*-Tri-chloro-propane**  $C_3H_4Cl_3$ , *i.e.*  $CH_3CHClCHCl_2$ . *Trichlorhydrin. Glyceryl chloride. Allyl trichloride*. (158°). S.G.  $\frac{d}{15}$  1.8984;  $\frac{d}{15}$  1.8878 (Perkin, C. J. 45, 532);  $\frac{d}{15}$  1.41 (O.). M.M. 7.897 at 21.6°.

**Formation.**—1. From glycerin dichlorhydrin (di-chloro-propyl alcohol) and  $PCl_5$  (Berthelot a. De Luca, A. Ch. [3] 48, 304; 52, 433; Fittig, A. 135, 359).—2. By passing Cl into allyl iodide under water (Oppenheim, Bl. [2] 2, 97).—3. One of the products of chlorination of propylene chloride (Belohoubek, B. 9, 924), or of propane (?) (Berthelot, A. 155, 105).—4. From propylene chloride and ICl at 160° (Friedel a. Silva, Z. 1871, 683).

**Reactions.**—1. Water (20 vols.) by heating at 160° for 24 hours forms glycerin.—2. KOH gives  $CH_3CClCH_2CH_2Cl$  (101°) and a little  $CHCl_2CH_2CH_2Cl$ .—3. Alcoholic KSH gives  $C_3H_7(SH)_2$ .—4. Alcoholic  $NH_3$  forms  $(C_2H_5Cl)_2NH$ .

5.  $AlI_3$  gives allyl iodide (Gustavson, C. O. 1877, 19).

***ααα*-Tri-chloro-propane**  $CH_3CH_2CCl_3$  (145°–150°). From  $Pr_3S$  and dry Cl in daylight (Spring a. Leorenier, Bl. [3] 48, 693).  $Ag_2O$  converts it into propionic acid.

***ααα*-Tri-chloro-propane**  $CH_3CHClCHCl_2$ . *α-Chloro-propylidene chloride*. (140°). S.G.  $\frac{d}{15}$  1.402;  $\frac{d}{15}$  1.372. Formed by chlorination of propylene or propylidene chloride in sunshine. Also, together with the preceding, by heating propylene chloride with ICl at 160° (Friedel a. Silva, C. R. 74, 805). Formed by union of  $CH_3CCl_2CH_2$  with Cl (Berthelot, A. 155, 105).

***ααα*-Tri-chloro-propane**  $CH_3CCl_2CH_2Cl$  (123°). S.G.  $\frac{d}{15}$  1.350;  $\frac{d}{15}$  1.318.

**Formation.**—1. From  $CH_3CCl_2CH_2$  by Cl in sunshine, or by ICl (F. a. S.).—2. From propylene chloride and Cl (Belohoubek, B. 9, 924).—3. From chloro-acetone and  $PCl_5$ .—4. From  $CH_3CCl_2CH_2$  and Cl at 0° in sunshine.

**Reactions.**—1. Water at high temperatures forms  $CH_3COCHO$  (?).—2. Alcoholic KOH gives two di-chloro-propylenes (75°) and (94°) (Friedel a. Silva, C. R. 74, 806).

**Tri-chloro-propane**  $CH_2ClCH_2CHCl_2$ . *β-Chloro-propylidene chloride*. (147°). S.G.  $\frac{d}{15}$  1.362. V.D. 4.95. Formed by the action of  $PCl_5$  on *β*-chloro-propionic aldehyde or on acrolein (Geuther, Z. 1865, 29; van Romburgh, Bl. [2] 37, 98). Alcoholic KOH gives di-chloro-propylene  $CH_2=CHCHCl_2$ .

**Tetra-chloro-propane**  $CH_3CCl_2CHCl_2$  (153°). S.G.  $\frac{d}{15}$  1.47. From di-chloro-acetone and  $PCl_5$  (Borsche a. Fittig, A. 133, 114). Also from allylene dichloride (Pinner, A. 179, 47). Apparently the same body is formed as a by-product in the preparation of tri-chloro-butyric aldehyde by chlorinating aldehyde (Pinner, B. 10, 1057). Alcoholic KOH gives  $C_2H_4Cl_2$  (115°).

**Tetra-chloro-propane**  $C_3H_2Cl_4$ , *i.e.*  $CH_2ClCH_2CH_2Cl$  (178°). (203°F. From propane and Cl in sunshine (Schorlemmer, Pr. 18, 29). Stellate groups of needles (from alcohol). Smells like camphor.

**Tetra-chloro-propane**  $CH_2ClCCl_2CH_2Cl$ . *Isosallylene tetrachloride*. (164°). S.G.  $\frac{d}{15}$  1.496. From  $CH_2ClCCl_2CH_2$  (95°) and Cl or HOCl (Fittig a. Pfeffer, A. 135, 360; Henry, C. R. 94, 1428). Also from  $CH_3CCl_2CH_2$  and Cl (Berthelot, A. 155, 105). Alcoholic KOH gives  $C_2H_4Cl_2$ . Alcoholic  $NH_3$  gives  $(C_2H_5Cl)_2NH$ . Sodium gives allylene.

**Tetra-chloro-propane**  $C_3H_2Cl_4$ , *i.e.*  $CH_3CHClCCl_2$  (145°). (c. 185°). From isopropyl iodide and Cl. Resembles camphor (B.). **Tetra-chloro-propane**  $C_3H_2Cl_4$  (c. 198°). S.G. 1.55. From propylene chloride and Cl (Cahours, A. 76, 283). Probably identical with the preceding, or, possibly, with the following.

**Tetra-chloro-propane**  $CH_2ClCHClCHCl_2$ . *Tetra-chloro-glycide. Allylidene tetrachloride*. (180°). S.G.  $\frac{d}{15}$  1.521. V.D. 6.8. From  $CH_3CCl_2CH_2Cl$  and Cl (Hartenstein, J. pr. [3] 7, 318). From  $CH_2=CHCHCl_2$  and Cl (van Romburgh, Bl. [2] 86, 558).

**Penta-chloro-propane**  $C_3HCl_5$ , *i.e.*  $CH_2ClCCl_2CHCl_2$  (194°). From di-chloro-acetone and  $PCl_5$  (Borsche a. Fittig, A. 133, 116). Alcoholic KOH gives  $C_2H_4Cl_2$  (156°).

**Penta-chloro-propane**  $C_3H_2Cl_5$ , *i.e.*  
 $CH_2Cl_2.CCl_2$ ? From  $CH_2Cl_2.OHCl_2$  and  $Cl$   
(B. a. F.). Prisms.

**Penta-chloro-propane**  $C_3H_2Cl_5$ . (c. 223°).  
From propylene chloride and  $Cl$  (Cahours, A.  
76, 283).

**Hexa-chloro-propane**  $C_3HCl_6$ , *i.e.*  
 $CCl_2.CHCl_2.CCl_2$ ? (250°). Formed by chlorina-  
ting propane in the brightest sunshine (Schor-  
lemmer, Pr. 18, 29). Liquid, smelling like  
camphor.

**Hexa-chloro-propane**  $C_3HCl_6$ , *i.e.*  
 $CCl_2.CHCl_2.CCl_2$ ? (c. 243°). S.G. 1.03. From  
propylene chloride and  $Cl$  (Cahours, A. 76, 283).

**Hepta-chloro-propane**  $C_3HCl_7$ . (260°). S.G.  
1.78. From propylene chloride and  $Cl$  (Cahours).

**Per-chloro-propane**  $C_3Cl_8$ . [160°]. (269°).  
From  $CH_2Cl_2.OHCl_2.CCl_2$  and  $ICl_3$  at 200°.  
Formed also, together with  $CCl_4$ , by heating iso-  
butane with  $IO_3$  at 240° (Kraft a. Merz, B. 8,  
1045); and, together with  $CCl_4$  and  $CCl_2$ , by the  
action of  $ICl_3$  on isobutyric acid (Kraft, B. 9,  
1085). Crystalline mass; v. e. sol. alcohol,  
ether and ligroin. At 250° it splits up into  
 $C_2Cl_4$  and  $CCl_4$ .

#### CHLORO-PROPANE SULPHONIC ACID

**$C_3H_7ClSO_3H$** . From the product of the action  
of  $ICl_3$  on propane sulphonic acid at 160° the  
salts  $(C_3H_7ClSO_3)_2Ba$ ,  $(C_3H_7ClSO_3)_2Ba$  aq. and  
 $(C_3H_7ClSO_3)_3Ba_3$ ,  $(C_3H_7ClSO_3)_3Ba_3$  may be isolated  
(Spring a. Winasinger, B. 16, 328).

**$\alpha$ -CHLORO-PROPIONIC ACID**  $C_3H_5ClO_2$ , *i.e.*  
 $CH_2.CHCl.CO_2H$ . Mol. w. 108.5. (186°). S.G. 21.28.

**Preparation.**—Calcio lactate (17 g.) is shaken  
with  $PCl_5$  (40 g.) and distilled from a bath of  
 $H_2SO_4$ . The distillate is mixed in the cold with  
the requisite quantity of cold water. The yield  
is 60 per cent. (J. M. Lovén, J. pr. [2] 29, 866;  
cf. Wurtz, A. 107, 192; Ulrich, A. 109, 271;  
Lippmann, A. 129, 81; Buchanan, Z. [2] 4, 523;  
Brühl, B. 9, 85; Mazzara, G. 12, 261).

**Properties.**—Liquid, miscible with water;  
blisters the skin.

**Reactions.**—1. Zinc and  $HCl$  convert it into  
propionic acid.—2. The solutions of the Ba and  
Ag salts change to lactate on boiling.—3. With  
conc. solution of  $KHS$  (2 mols.) it gives thiolactate  
and thiodilactate of potassium.

**Salts.**— $AgA'$ .— $BaA'$ .

**Methyl ether**  $MeA'$ . (182.5°). S.G. 4  
1.075.  $\mu_D$  1.423 (Kahlbaum, B. 12, 344).

**Ethyl ether**  $EtA'$ . (147°). S.G. 29 1.0869.  
 $\mu_D$  1.4287.  $R_D$  51.12 (Brühl, A. 203, 24).

**Reactions.**—1. When heated with thiurea 5  
hours at 100° it gives the hydrochloride  
of acetylthio-urea:  $CS \begin{smallmatrix} NH_2.C_2H_5 \\ NH.CO \end{smallmatrix}$ .—2. With

potassium sulphocyanide 5 hours at 150° it gives  
 $CH_3.CH(SCN).CO_2Et$  (Freytag, J. pr. 128, 880).

3.  $NaOEt$  gives  $CH_3.CH(OEt).CO_2Et$ .

**Amide**  $CH_3.CHCl.CONH_2$ . (80°). Scales;  
v. sol. water (Beckurts a. Otto, B. 9, 1692).

**Chloride**  $CH_3.CHCl.COCl$ . (110°). V.D.  
4.38. S.G. 21 1.289 (Henry, C. R. 100, 114).

**Nitrile**  $CH_3.CHCl.CN$ . (122°). Pungent  
liquid.

**$\beta$ -Chloro-propionamide**  $CH_3.CH_2.CO_2H$ .  
[41°]. (B. a. O.). [88°] (H.). (304°).

**Formation.**—1. By heating hydraacrylic acid  
with fuming  $HCl$  at 120° (Beckurts a. Otto, B.

18, 226).—2. From its chloride, which is formed  
by the union of ethylene with  $COCl_2$  (Lippmann,  
A. 129, 81; Henry, C. R. 100, 114).—3. From  
acrylic acid and  $HCl$  (Linnemann, A. 163, 96).—  
4. From  $\beta$ -iodo-propionic acid and chlorine-  
water (Richter, Z. 1868, 451).

**Properties.**—White plates; v. e. sol. water  
and alcohol. Does not blister the skin.

**Methyl ether**  $MeA'$ . (156°).

**Ethyl ether**  $EtA'$ . (163°). V.D. 4.94.  
S.G. 21 1.116.

**Chloro-ethyl ether**  $CH_2Cl.CH_2A'$ .  
(c. 218°). S.G. 21 1.282. From the acid and  
 $CH_3OH.CH_2Cl$  (H.).

**Chloride**  $CH_3.CHCl.COCl$ . (144°). V.D.  
4.42. S.G. 21 1.331.

**$\alpha\alpha$ -Di-chloro-propionic acid**  $CH_2.CCl_2.CO_2H$ .  
(c. 188°).

**Formation.**—1. From pyruvic acid and  $PCl_5$   
(Klimenko, B. 8, 465; 5, 477; Beckurts a. Otto,  
B. 11, 386).—2. The nitrile is formed by chlori-  
nating propionitrile (Otto, A. 132, 181; B. 9,  
1877).

**Properties.**—Liquid; v. sol. water; insol.  
conc.  $HCl$ . Solidified by cold. Converted by  
zinc and  $HCl$  into propionic acid. Water at  
140° gives pyruvic acid. Boiling alcoholic  
 $KOH$  gives  $\alpha$ -chloro-acrylic acid. Reduced  
silver forms  $CO.H.CMe:OMe.CO_2H$  and  $CO_2H$ ;  
 $CMcCl.CMeCl.CO_2H$ .

**Salts.**— $NH_4A'$ .— $KA'$  5aq. —  $BaA'$ , aq. —  
 $CaA'$ , aq. —  $CaA'$ , 3aq. —  $ZnA'$ , aq.: easily soluble  
flat needles. —  $AgA'$ .—On heating with water it  
decomposes into pyruvic acid, dichloropropionic  
acid, and  $AgCl$ . On heating the dry salt it  
yields pyruvic-dichloropropionic anhydride  
 $CH_3.CO.CO \begin{smallmatrix} \diagup \\ CH_2.CCl_2.CO \end{smallmatrix}$  and  $AgCl$  (Beckurts a. Otto,  
B. 18, 227).

**Methyl ether**  $MeA'$ . (144°).

**Ethyl ether**  $EtA'$ . (167°) (B. a. O.);  
(160°) (K.). S.G. 21 1.249.

**Isobutyl ether**  $CH_3.PrA'$ . (184°).

**Allyl ether**  $C_3H_5A'$ . (177°).

**Chloride**  $CH_3.CCl_2.COCl$  (c. 110°).

**Anhydride**  $(CH_3.CO)_2CO$ . (191°).

**Amide**  $CH_3.CCl_2.CONH_2$ . [116°]. Mono-  
clinic laminae (Haushofer, Z. K. 7, 267).—  
 $(CH_3.CCl_2.CONH)_2Hg$  aq.: needles.

**Nitrile**  $CH_3.CCl_2.CN$ . (105°). S.G. 21 1.431.

**Paranitrile**  $(CH_3.CCl_2)_2C_2N_4$  (?). [74°]. S.  
(alcohol) 14 at 20°. Chlorine acting upon pro-  
pionitrile forms a liquid di-chloro-propionitrile  
(104°–107°) and a solid isomeride [74°]; the for-  
mation of the latter is promoted by a low tem-  
perature. Both give the same di-chloro-propio-  
nic acid on saponification, hence the solid form  
is probably a polymeride of the liquid. The  
liquid form sometimes changes spontaneously  
into the solid form (Otto a. Voigt, J. pr. [2] 86,  
79). **Reactions of the paranitrile.**—1.  $H_2SO_4$   
(1 vol.) mixed with water (1 vol.) at 180° gives  
 $\alpha$ -di-chloropropionic acid.—2. Alcoholic  $NH_3$   
gives di-chloro-propionamide.—3. Zinc and  
acetic acid reduce it to  $(C_2H_5)_2C_2N_4$  (195°).—  
4. Zinc acting on a solution in dilute alcohol  
forms a base  $C_4H_7N_3$ , [111°], (c. 273°), crys-  
tallising from petroleum ether in needles or  
plates, v. sol. ether and alcohol, v. sl. sol.  
water. It forms salts:  $BHCl$ .— $B'H_2.PtCl_2$ .—  
 $AgC_4H_7N_3$ , 4aq.

***α,β*-Di-chloro-propionic acid**  
 $\text{CH}_2\text{Cl.CHCl.CO}_2\text{H}$ . [50°]. (210°).

**Formation.**—1. From glyceric acid and HCl (Werigo, *B.* 12, 178; cf. *A.* 170, 163).—2. From di-chloro-propyl alcohol  $\text{CH}_2\text{Cl.CHCl.CH}_2\text{OH}$  by oxidation (Henry, *B.* 7, 414; Werigo a. Melikoff, *B.* 10, 1500).—3. From  $\alpha$ -chloro-acrylic acid and HCl at 180° (W. a. M.).—4. Formed from  $\text{CH}_2(\text{OH}).\text{CHCl.CO}_2\text{H}$  and fuming HCl at 100° (Melikoff, *J. R.* 13, 163; *C. C.* 1881, 354).

**Properties.**—Small needles. Alcoholic KOH gives  $\alpha$ -chloro-acrylic acid.— $\text{HO.PbA}$ .

**Ethyl ether EtA.** (184°). S.G.  $\frac{4}{4}$  1.2461.  $n_D^{20}$  1.4588.  $n_D^{25}$  59.75 (Brühl, *A.* 203, 25). Successive treatment with alcoholic KCy and KOH gives fumaric and inactive malic acids (Werigo a. Tanatar, *A.* 174, 887).

***β,β*-Di-chloro-propionic acid**  $\text{CHCl}_2.\text{CH}_2.\text{CO}_2\text{H}$ . [56°]. From  $\beta$ -chloro-acrylic acid and aqueous HCl at 80° (Otto a. Fromme, *A.* 239, 268). Prisms, v. sol. alcohol, ether, benzene, chloroform, and water. Converted by alcoholic KOH into  $\text{CHCl}_2.\text{CHCl.CO}_2\text{H}$ .

**Ether EtA.** (171°–175°).

**Amide**  $\text{CHCl}_2.\text{CH}_2.\text{CONH}_2$ . [140°]: needles.

**Tri-chloro-propionic acid** (?)  $\text{C}_2\text{H}_2\text{Cl}_3\text{O}_2$  (?). [60°]. From per-chloro-succinic ether and conc. KOHAq (Malaguti, *A. Ch.* [3] 16, 67, 72, 82).—AgA'.

#### ***β*-CHLORO-PROPIONIC ALDEHYDE**

$\text{C}_2\text{H}_4\text{ClO}$  i.e.  $\text{CH}_2\text{Cl.CH}_2.\text{CHO}$ . *Acrolein hydrochloride*. (c. 45°) at 10 mm. (130°–170°). Formed, together with the paraldehyde, by passing gaseous HCl into acrolein (Geuther a. Cartmell, *A.* 112, 8; Krestownikoff, *J. R.* 11, 249; Grimaux a. Adam, *C. R.* 92, 300). Liquid. Reduces Fehling's solution. Rapidly changes to the solid paraldehyde.  $\text{HNO}_3$  forms  $\beta$ -chloro-propionic acid.

***β*-Chloro-propionic paraldehyde**  $(\text{C}_2\text{H}_4\text{ClO})_3$  (?). [33–5°]. (170°–175°) at 15 mm. Formed by spontaneous polymerisation of the preceding, into which it is reconverted by distillation under ordinary pressure. Needles. Insol. water. It does not reduce Fehling's solution. Not acted upon by water or baryta at 100°, nor by  $\text{AgOAc}$  or  $\text{Pb(OAc)}_2$  at 120°. Water at 120° gives HCl and metacrolein. Distillation over solid KOH also forms some metacrolein.

#### ***α,β*-Di-chloro-propionic aldehyde**

$\text{CH}_2\text{Cl.CHCl.CO}_2\text{H}$ . From acrolein and Cl (Aronstein, *A. Suppl.* 3, 190). Oil. Its alcoholate  $\text{CH}_2\text{Cl.CHCl.CH(OH)(OEt)}$  boils at 150°–155°.

***β*-CHLORO-PROPYL ALCOHOL**  $\text{C}_2\text{H}_4\text{ClO}$  i.e.  $\text{CH}_2\text{Cl.CH}_2.\text{CH}_2\text{OH}$ . *Trimethylene chlorhydrin*. (161° cor.). S.G.  $\frac{4}{4}$  1.182.  $n_D^{20}$  8.50. From trimethylene glycol  $\text{CH}_2\text{O.HO.CH}_2\text{O.HO}$  and HCl at 100° (Reboul, *A. Ch.* [5] 14, 491).

#### ***α*-Chloro-isopropyl alcohol**

$\text{CH}_2\text{Cl.CH(OH).CH}_2\text{Cl}$ . *Propylene chlorhydrin*. (128°). S.G.  $\frac{4}{4}$  1.180.

**Formation.**—1. From propylene glycol and HCl (Oser, *A. Suppl.* 1, 254) or  $\text{S}_2\text{O}_5$  (Morley, *B.* 18, 1806).—2. From allyl chloride (1 pt.) and conc.  $\text{H}_2\text{SO}_4$  (8 pts.) at 100°; the product being distilled with water (10 pts.) (Cypenbeim, *A. Suppl.* 6, 387).—3. From propylene and HOCl (Markownikoff, *Z.* 1870, 423).

**Properties.**—Liquid, sol. water. May probably contain  $\text{CH}_2\text{Cl.CHCl.CH}_2\text{OH}$ .

**Reactions.**—1.  $\text{P}_2\text{O}_5$  gives allyl chloride and

chloro-propylene (Henry, *Z.* 1871, 600).—2. The chlorhydrin obtained by the action of  $\text{S}_2\text{O}_5$  upon propylene glycol gives chloro-acetone on oxidation with  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$ , or with  $\text{HNO}_3$  (Morley a. Green, *B.* 18, 24; *C.*  $\frac{4}{4}$  1.132). The chlorhydrin obtained from propylene and HOCl is oxidised (by chromic mixture) to chloro-acetone according to Markownikoff, or (by  $\text{HNO}_3$ ) to  $\alpha$ -chloro-propionic acid according to Henry (*B.* 7, 1649, 1790).—3.  $\text{HNO}_3$  gives chloro-acetic acid (Henry, *Bl.* [2] 25, 389).—4. Heating with ZnO or PbO gives propionic aldehyde and acetone (Eltokoff, *J. R.* 10, 222).

**Benzoyl derivative**  $\text{C}_6\text{H}_5\text{C(O)OEt}$ . (269° cor.). S.G.  $\frac{4}{4}$  1.172;  $\frac{4}{4}$  1.149. From the alcohol and  $\text{BzCl}$ . Oil. Alkalis form propylene oxide. ZnEt<sub>2</sub> gives propylene ethyl phenyl ketate  $\text{C}_6\text{H}_5\text{C(O)OEt.C}_2\text{H}_5$  (Morley a. Green, *C. J.* 47, 134; *B.* 17, 3015).

**Ethyl ether**  $\text{CH}_2\text{Cl.CH(OEt).CH}_2\text{Cl}$ . (118°). S.G.  $\frac{4}{4}$  0.984. From di-chloro-di-ethyl oxide and  $\text{ZnMe}_2$  (Lieben, *A.* 146, 225; 178, 14).

#### ***α,β*-Di-chloro-propyl alcohol**

$\text{CH}_2\text{Cl.CHCl.CH}_2\text{OH}$ . *Dichloride of allyl alcohol*. (182°). S.G.  $\frac{4}{4}$  1.380 (T.);  $\frac{4}{4}$  1.355 (G.).

**Formation.**—1. From allyl alcohol and Cl (Tollens, *A.* 156, 164; Hübner a. Müller, *A.* 159, 168).—2. From allyl chloride and HOCl (v. Geyerfeldt, *A.* 154, 247; *B.* 6, 720; Henry, *B.* 3, 352; 7, 414).—3. Together with its isomeride, by passing dry HCl into glycerin (Fauconier a. Sanson, *Bl.* [2] 48, 236). According to Markownikoff (*A.* 208, 349) passing HCl into a mixture of glycerin and aqueous HCl only produces  $\text{CH}_2\text{Cl.CH(OH).CH}_2\text{Cl}$  (cf. Tollens, *Z.* 1869, 174).

**Properties.**—Viscid oil, sl. sol. water, sol. alcohol. Aqueous NaOH gives epichlorhydrin (119°).  $\text{HNO}_3$  gives  $\alpha,β$ -di-chloro-propionic acid. **Di-chloro-isopropyl alcohol**  $\text{C}_2\text{H}_4\text{ClO}$  i.e.  $\text{CH}_2\text{Cl.CH(OH).CH}_2\text{Cl}$ . *Glycerin dichlorhydrin*. Mol. w. 129. (176° i.v.). S.G.  $\frac{4}{4}$  1.383;  $\frac{4}{4}$  1.367 (Markownikoff, *A.* 208, 349).  $n_D^{20}$  8.11 at 19°.

**Formation.**—1. From glycerin and HCl (Berthelot, *A.* 92, 302; Hübner a. C. Müller, *Z.* [2] 6, 344; Watt, *B.* 5, 257).—2. From glycerin and  $\text{S}_2\text{Cl}_2$  (Carius, *A.* 122, 73; Claus, *A.* 168, 42).—3. From epichlorhydrin and fuming HCl (Reboul, *A. Suppl.* 1, 225).—4. Together with its isomeride, by the union of HOCl with allyl chloride (Henry, *B.* 8, 352).

**Reactions.**—1. *Chromic acid mixture* oxidises it to  $\alpha$ -di-chloro-acetone (43°) and chloro-acetic acid.—2. *Sodium amalgam* converts it into isopropyl alcohol (Buff, *A. Suppl.* 5, 250).—3. *Sodium* added to its ethereal solution forms allyl alcohol ( $\text{H. a. M.}$ ; Tornøe, *B.* 21, 1282).—4. Alcoholic (4 p.c.)  $\text{NH}_3$  (21 mols.) forms amorphous 'chlorhydrinimide'  $\text{C}_2\text{H}_4\text{N}_2\text{Cl}_2\text{O}$ . Weaker alcoholic  $\text{NH}_3$  (1 p.c.) forms hydrochlorides of 'diamido-hydrin'  $\text{C}_2\text{H}_4\text{N}_2\text{O}$ , and of 'glycidamine'  $\text{C}_2\text{H}_4\text{NO}$  (Claus, *A.* 168, 29; *B.* 8, 244).—5. *Aniline* forms  $\text{C}_6\text{H}_5\text{ONPh}$ .—6. Solid NaOH gives epichlorhydrin  $\text{C}_2\text{H}_4\text{ClO}$ .—7. Br at 100° gives di-chloro-di-bromo-acetone  $\text{CBr}_2\text{Cl.CO.CH}_2\text{Cl}$  and chloro-tri-bromo-acetone (Grimaux a. Adam, *Bl.* [2] 82, 18).—8.  $\text{P}_2\text{O}_5$  acts vigorously, forming di-chloro-propylene.

#### **Formyl derivative**

$\text{CH}_2\text{Cl.CH(OCHO).CH}_2\text{Cl}$ . (c. 152°) at 22 mm. Formed by heating the alcohol with nitro-

methane at 220° (Pfungst, *J. pr.* [2] 84, 28). The nitro-methane may perhaps first form hydroxylamine and formic acid:  $\text{CH}_3\text{NO}_2 + \text{H}_2\text{O} = \text{CH}_3\text{O} + \text{NH}_3\text{O}$ ; but no hydroxylamine could be found.

**Acetyl derivative**  $\text{CH}_3\text{Cl}.\text{CH}(\text{OAc}).\text{CH}_2\text{Cl}$ . (204°) (B. a. L.; T.); (195°) (H.); (c. 142° at 25 mm.) (P.). S.G.  $\frac{1}{4}$  1.283 (T.);  $\frac{1}{4}$  1.274 (H.).

**Formation**.—1. From glycerin and  $\text{AcCl}$ .—2. By passing  $\text{HCl}$  at 100° into a mixture of glycerin and  $\text{HOAc}$  (Berthelot a. De Luca, *A. Ch.* [3] 52, 459).—3. From  $\text{CH}_3\text{Cl}.\text{CH}(\text{OH}).\text{CH}_2\text{Cl}$  and  $\text{AcCl}$  (Henry, *B.* 4, 704).—3. From epichlorohydrin and  $\text{AcCl}$  (Truchot, *A.* 138, 297).—4. From the formyl derivative and  $\text{AgOAc}$  (Pfungst, *J. pr.* [2] 84, 28).

**Butyryl derivative**  $(\text{CH}_3\text{CH}_2\text{CH}_2\text{CO})_2\text{CH}.$  (227°). S.G.  $\frac{1}{4}$  1.194 (T.).

**Isobutyryl derivative**  $(\text{CH}_3\text{CH}_2\text{CH}_2\text{CO})_2\text{CH}.$  (245°) at 737 mm. S.G.  $\frac{1}{4}$  1.149 (Truchot, *A.* 138, 297).

• **Benzoyl derivative**  $(\text{CH}_2\text{Cl}).\text{CH}(\text{OBz}).$  (222°) at 40 mm. S.G.  $\frac{1}{4}$  1.441. From epichlorohydrin and  $\text{BzCl}$  at 180° (T.). Also from the formyl derivative and  $\text{BzCl}$  (P.).

**Tri-chloro-isopropyl alcohol**  $\text{CCl}_3.\text{CH}(\text{OH}).\text{CH}_3.$  [49°]. (150°–160°). From chloral by successive treatment with  $\text{ZnMe}_2$  and water (Garzaroli-Thurnsackh, *A.* 210, 77). Small deliquescent needles (from ether). May be sublimed. Smells like camphor.

**TRI-CHLORO-PROPYLENE**  $\text{C}_3\text{H}_2\text{Cl}_3\text{NH}_2$ . Formed by the action of  $\text{Sn}$  and  $\text{HCl}$  on dinitro-allylene-dichloride  $\text{C}_3\text{H}_2\text{Cl}_2(\text{NO}_2)_2$  (Pinner, *A.* 179, 55). Oil; may be distilled.

•  **$\beta$ -CHLORO- $\alpha$ -PROPYL-CINNAMIC ACID**  $\text{C}_6\text{H}_5.\text{CCl}(\text{C}_6\text{H}_5).\text{CO}_2\text{H}$ . [121°]. From its ether, which is formed by treating propyl-benzoyl-acetic ether with  $\text{PCl}_5$  (W. H. Perkin, jun., *C. J.* 49, 163). Triclinic prisms;  $a:b:c = .797:1:1.740$ ;  $\alpha = 122^\circ 33'$ ;  $\beta = 106^\circ 21'$ ;  $\gamma = 69^\circ 25'$  (Haushofer). May be sublimed. V. sol. alcohol, ether, benzene, chloroform, and  $\text{HOAc}$ ; m. sol. ligroin.

• **Ethyl ether EtA.** (248°) at 300 mm. Oil.  **$\beta$ -CHLORO-PROPYLENE**  $\text{CH}_2=\text{CH}.\text{CH}_2\text{Cl}$  v. ALLYL CHLORIDE.

•  **$\alpha$ -Chloro-propylene**  $\text{CHCl}:\text{CH}.\text{CH}_3$ , *Propenyl chloride*. (35°). Formed, together with some of the following isomeride, by treating propylene chloride with alcoholic  $\text{KOH}$  (Cahours, *C. R.* 31, 291). Obtained by heating propylidene chloride  $\text{CH}_3.\text{CH}_2.\text{CHCl}_2$  with alcoholic  $\text{KOH}$  (Reboul, *A. Ch.* [5] 14, 462). Formed also by heating the neutral solution of the alkaline salts of the liquid  $\alpha$ -di-chloro-butyric acid (Wislicenus, *B.* 20, 1010). Liquid. Br at 15° forms  $\text{C}_3\text{H}_5\text{ClBr}_2$  (177°). Alcoholic  $\text{KOH}$  gives allylene.  $\text{HBr}$  gives  $\text{CH}_3.\text{CH}_2.\text{CHClBr}$  (110°) and a small quantity of  $\text{CH}_3.\text{CHBr}.\text{CH}_2\text{Cl}$  (121°).

**Allo- $\alpha$ -chloro-propylene**  $\text{CHCl}:\text{CH}.\text{CH}_3$ . (33°). Formed by heating the neutral solution of the alkaline salts of  $\alpha$ -di-chloro-butyric acid [63°] (Wislicenus, *B.* 20, 1010).

•  **$\alpha$ -Chloro-propylene**  $\text{CH}_2=\text{CCl}.\text{CH}_3$ . (28°) (O.); (25–5°) (F.). S.G.  $\frac{1}{4}$  .9307 (F.);  $\frac{1}{4}$  .931 (O.). V.D. 3.83 (calc. 2.66). The chief product of the action of alcoholic  $\text{KOH}$  on propylene chloride. Formed also by treating  $\text{CH}_2\text{Cl}.\text{CCl}_2.\text{CH}_3$  (from acetone and  $\text{PCl}_5$ ) with alcoholic  $\text{KOH}$ , with  $\text{NH}_3$ , or with  $\text{AgOAc}$ .

**Reactions**.—1.  $\text{H}_2\text{SO}_4$  followed by water gives **III.**

acetone (Oppenheim, *C. R.* 65, 354; *A. Suppl.* 6, 357).—2. Water at 160° also forms acetone.—3. Br gives  $\text{CH}_2\text{Br}.\text{CClBr}.\text{CH}_3$  (c. 173°) (Friedel, *A. Ch.* [4] 16, 343).—4. Alcoholic  $\text{KOH}$  at 120° gives allylene (Friedel, *C. R.* 59, 294).—5. HI at 100° gives  $\text{CH}_3.\text{CCl}.\text{CH}_3$ .—6. Cl in sunshine forms  $\text{CH}_2\text{Cl}.\text{CCl}_2.\text{CH}_3$  (127°). In the dark Cl forms  $\text{CH}_2.\text{CCl}.\text{CH}_2\text{Cl}$ .—7.  $\text{HBr}$  gives  $\text{CH}_3.\text{CBrCl}.\text{CH}_3$  (93°).—8.  $\text{HClO}$  gives chloro-acetone (Linne-mann, *A.* 138, 122).

•  **$\alpha$ -Di-chloro-propylene**  $\text{CH}_2=\text{CCl}.\text{CH}_2\text{Cl}$ . ( *$\alpha$ -Epidichlorhydrin*. ( *$\alpha$ -Chloro-allyl chloride*. (94°). S.G.  $\frac{1}{4}$  1.236;  $\frac{1}{4}$  1.204.

**Formation**.—1. Together with the following, by the action of Cl on  $\text{CH}_2\text{Cl}.\text{CCl}_2.\text{CH}_3$  in the shade (Friedel a. Silva, *C. R.* 73, 957; 74, 846; 75, 81; Fittig, *A.* 135, 859), or of  $\text{KOH}$  or  $\text{NEt}_3$  on  $\text{CH}_2\text{Cl}.\text{CHCl}.\text{CH}_2\text{Cl}$  (Reboul, *A. Suppl.* 1, 229; *C. R.* 95, 993).—2. From  $\text{CH}_2\text{Cl}.\text{CCl}_2.\text{CH}_2\text{Cl}$  and alcoholic  $\text{KOH}$  (F. a. S.).

**Reactions**.—1. Br forms  $\text{C}_3\text{H}_2\text{Cl}_3\text{Br}_2$  (205°).—2. Fuming  $\text{HCl}$  at 100° gives  $\text{CH}_2.\text{CCl}_2.\text{CH}_2\text{Cl}$ .—3.  $\text{H}_2\text{SO}_4$  followed by water gives chloro-acetone (Henry, *B.* 5, 186).—4. Alcoholic  $\text{KOH}$  gives  $\text{CH}_2.\text{CCl}.\text{CH}_2\text{OEt}$  (110°).—5.  $\text{ClOH}$  gives  $\alpha$ -di-chloro-acetone [42°] and  $\text{CH}_2\text{Cl}.\text{CCl}_2.\text{CH}_2\text{Cl}$  (164°) (Henry, *C. R.* 94, 1428).—6.  $\text{NEt}_3$  at 100° forms  $\text{CH}_2.\text{CCl}.\text{CH}_2.\text{NEt}_3$  (Reboul, *C. R.* 95, 993).—7. Sodium gives allylene and propylene.—8. Alcoholic  $\text{KCy}$  followed by  $\text{KOH}$  gives tricarballic acid and a little oxy-crotonic acid (Claus, *A.* 170, 136).

•  **$\omega$ -Di-chloro-propylene**  $\text{CHCl}:\text{CH}.\text{CH}_2\text{Cl}$ . ( *$\beta$ -Epidichlorhydrin*. ( *$\beta$ -Chloro-allyl chloride*. (106°) (F. a. S.); (110° or.) (R.). S.G.  $\frac{1}{4}$  1.226 (R.);  $\frac{1}{4}$  1.250 (F. a. S.). V.D. 3.83.

**Formation**.—1. Together with the preceding, by the action of solid  $\text{KOH}$  on  $\text{CH}_2\text{Cl}.\text{CHCl}.\text{CH}_2\text{Cl}$  (F. a. S.).—2. In the pure state by treating  $\text{CH}_2\text{Cl}.\text{CH}(\text{OH}).\text{CH}_2\text{Cl}$  with  $\text{P}_2\text{O}_5$  (Hartenstein, *J. pr.* [2] 7, 310).—3. A by-product in the action of  $\text{PCl}_5$  on acrolein (Geuther, *Z.* 1865, 25; v. Romburgh, *Bl.* [2] 86, 549).

**Reactions**.—1. Cl gives  $\text{CH}_2\text{Cl}.\text{CHCl}.\text{CHCl}_2$  (180°).—2. Does not unite with  $\text{HCl}$ .—3. Alcoholic  $\text{KOH}$  gives  $\text{CHCl}:\text{CH}.\text{CH}_2\text{OEt}$  (123°).—4. Aqueous  $\text{KOH}$  gives  $\beta$ -chloro-allyl alcohol.—5. Sodium forms isocallylene  $\text{CH}_2:\text{C}:\text{CH}$  (Hartenstein).—6. Br gives  $\text{CHClBr}.\text{CHBr}.\text{CH}_2\text{Cl}$  (212°).

•  **$\omega$ -Di-chloro-propylene**  $\text{CH}_2=\text{CCl}:\text{CHCl}$ . *Allylene dichloride*. (76°) (F. a. S.); (78°) (P. a. K.).

**Formation**.—1. From  $\text{CH}_2\text{Cl}.\text{CCl}_2.\text{CH}_2\text{Cl}$  by treatment with alcoholic  $\text{KOH}$  (Friedel a. Silva, *Bl.* [2] 17, 886; *J.* 1873, 322).—2. From tri-chloro-butyric aldehyde and aqueous  $\text{KOH}$  (Pinner a. Krämer, *A.* 158, 47; 179, 44).

**Reactions**.—1. Br forms  $\text{CH}_2\text{Br}.\text{CClBr}.\text{CHClBr}$  (188°).—2. Sodium forms allylene  $\text{CH}_2:\text{C}:\text{CH}$ .

• **Di-chloro-propylene**  $\text{CH}_2=\text{CH}.\text{CHCl}_2$ . *Allylidene chloride*. *Acrolein chloride*. (85° or.). S.G.  $\frac{1}{4}$  1.170. V.D. 3.83. Formed, together with  $\text{CHCl}:\text{CH}.\text{CH}_2\text{Cl}$  and  $\text{CHCl}:\text{CH}.\text{CH}_2\text{OH}$ , by the action of  $\text{PCl}_5$  on acrolein (Geuther, *A.* 114, 26; *Z.* 1865, 25; v. Romburgh, *Bl.* [2] 86, 549).

**Reactions**.—1. Cl forms  $\text{CH}_2\text{Cl}.\text{CHCl}.\text{CHCl}_2$  (180°).—2. KI or  $\text{CaI}_2$  at 100° gives  $\text{C}_3\text{H}_5\text{CHI}$  (162°) (v. Romburgh, *R. T. C.* 1, 233).—3. Potassium acetate gives  $\text{C}_3\text{H}_5(\text{OAc})_2$  (c. 180°).—  
K

4. Sodium has no action.—5. Alcoholic KOH gives  $\text{CH}_3\text{CH}(\text{OH})(\text{OEt})$  (c.  $118^\circ$ ).—6. NaOEt gives  $\text{CH}_3\text{CH}(\text{OH})(\text{OEt})$  (Aronstein, *A. Suppl.* 3, 181). 7. Conc.  $\text{HClAq}$  at  $100^\circ$  changes it to the isomeric  $\text{CH}_3\text{CH}(\text{CH}_3)\text{CHCl}$ .—8.  $\text{NH}_3$  at  $100^\circ$  forms acrolein-ammonia.

Tri-chloro-propylene  $\text{CH}_2\text{Cl.CCl}:\text{CH}_2\text{Cl}$  ( $142^\circ$ ). S.G.  $^{29}$  1.414. From  $\text{CH}_2\text{Cl.CCl}:\text{CH}_2\text{Cl}$  and alcoholic KOH (Pfeffer a. Fittig, *A.* 135, 861).

Tri-chloro-propylene  $\text{CH}_2\text{Cl.CCl}:\text{CH}_2\text{Cl}$  ( $115^\circ$ ). S.G.  $^{24}$  1.387. From  $\text{CH}_2\text{Cl.CCl}:\text{CH}_2\text{Cl}$  and alcoholic KOH (Borsche a. Fittig, *A.* 133, 117). Cl forms solid  $\text{C}_2\text{H}_3\text{Cl}_3$ .

Tri-chloro-propylene  $\text{C}_2\text{H}_3\text{Cl}_3$  ( $139^\circ$ ). From the crude product of the chlorination of aldehyde (tri-chloro-butyric aldehyde) and aqueous NaOH (Pinner, *B.* 5, 207). Alcoholic KOH converts it into  $\text{C}_2\text{H}_3\text{Cl}_3$ .

Tetra-chloro-propylene  $\text{C}_2\text{H}_2\text{Cl}_4$  ( $165^\circ$ ). From  $\text{C}_2\text{H}_3\text{Cl}_3$  (derived from acetone) and alcoholic KOH (B. a. F.).

CHLORO-PROPYLENE GLYCOL v. GLYCERIN *chlorhydrin*.

CHLORO-PROPYLIDENE CHLORIDE v. TRI-CHLORO-PROPANE.

CHLORO-DI-ISOPROPYL-KETONE

$\text{C}_6\text{H}_4\text{CO.C}_2\text{H}_5\text{Cl}$  ( $142^\circ$ ). Prepared by passing Cl into di-isopropyl-ketone at  $0^\circ$  (Barbaglia a. Gucci, *B.* 13, 1870; *G.* 11, 92). Liquid.

Di-chloro-di-isopropyl-ketone  $\text{C}_6\text{H}_4\text{Cl}_2\text{CO}$  ( $176^\circ$ ). Prepared by passing chlorine into di-isopropyl-ketone at the ordinary temperature (B. a. G.). Colourless liquid. Turpentine-like odour.

Tri-chloro-di-isopropyl-ketone  $\text{C}_6\text{H}_3\text{Cl}_3\text{CO}$  (about  $229^\circ$ ). Prepared by passing Cl into boiling di-isopropyl-ketone (B. a. G.). Liquid with pungent turpentine-like odour.

CHLORO-ISOPROPYL NITRATE

$\text{CH}_3\text{CH}(\text{NO}_2)\text{CH}_2\text{Cl}$  ( $158^\circ$ ). S.G.  $^{12}$  1.28. From chloro-isopropyl alcohol  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  (Henry, *A. Ch.* [4] 27, 263).

$\alpha$ S-Di-chloro-propyl nitrate

$\text{CH}_2\text{Cl.CHOCl.CH}_2\text{NO}_2$  ( $160^\circ$ ). S.G.  $^{12}$  1.3. From  $\text{CH}_2\text{Cl.CHOCl.CH}_2\text{OH}$  and  $\text{HNO}_3$  (Henry, *B.* 7, 409).

Di-chloro-isopropyl nitrate  $(\text{CH}_3\text{Cl})_2\text{CH.NO}_2$  ( $190^\circ$ – $190^\circ$ ). S.G.  $^{12}$  1.465. Formed from  $\text{CH}_3\text{Cl.CH}(\text{OH}).\text{CH}_2\text{Cl}$ ,  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  (Henry, *A.* 155, 187).

(Py. 8.) CHLORO-(B. 8.)-ISOPROPYL QUINOL-

INE  $\text{C}_6\text{H}_3(\text{C}_2\text{H}_5)\text{CH}(\text{CH}_3)\text{CH}_2\text{Cl}$  *Chloro-cumquinol-*

*ine*. Formed by heating isopropyl-carbostyryl with  $\text{PCl}_5$  (Widmann, *B.* 19, 265). Yellowish oil. Heavier than water. V. sol. alcohol, ether, benzene, &c., nearly insol. water. Sparingly volatile with steam. Weak base.— $\text{B}'_2\text{H}_3\text{Cl}_2\text{PtCl}_4$  ( $188^\circ$ ); yellow monoclinic prisms.

CHLORO-PYRENE v. PYRENE.

CHLORO-PYRIDINE  $\text{C}_5\text{H}_4\text{ClN}$  *etc.*

$\text{N} \begin{smallmatrix} \text{CH.CCl} \\ \text{CH.CH} \end{smallmatrix} \text{CH}$  ( $148^\circ$ ). V.D. 57 (obs.).

*Formation*.—1. By heating potassium pyrrol with chloroform in presence of ether; the residue after evaporation of the ether is boiled with dilute  $\text{HCl}$  to resinify the unaltered pyrrol, and after making alkaline with KOH, the chloro-pyridine is distilled over with steam (Ciamician

a. Dennstedt, *G.* 11, 224, 300; *B.* 14, 1158).—2. By the action of  $\text{COCl}_2$ , chloral, or tri-chloro-acetic ether on pyrrol-potassium (Ciamician a. Dennstedt, *B.* 15, 1179).—3. From oxy-pyridine and  $\text{PCl}_5$  (Lieben a. Haitinger, *M.* 6, 815).

*Properties*.—Pungent alkaline liquid; m. sol. water.

*Reactions*.—1. HI at  $145^\circ$  gives iodo-pyridine; at  $200^\circ$  it forms pyridine (L. a. H.).—2. Br and I form additive compounds.—3. Sodium amalgam forms chloro-piperidine  $\text{C}_5\text{H}_9\text{ClN}$ .

*Salts*.— $\text{B}'\text{HCl}$ : deliquescent crystals.— $\text{B}'_2\text{H}_3\text{PtCl}_4$ : monoclinic needles;  $a:b:c = 1.197:1.172$ ;  $\beta = 109^\circ 48'$  (C. a. D.);  $a:b:c = 1.04:1.125$ ;  $\beta = 72^\circ 42'$  (L. a. H.). Converted by heat into  $\text{B}'_2\text{PtCl}_4$ .

*Hexahydrate*  $\text{C}_5\text{H}_4\text{ClN} \cdot 6\text{H}_2\text{O}$  *Chloropyridine*. From chloro-pyridine by reduction with sodium amalgam or with Zn and  $\text{HCl}$ .— $\text{B}'_2\text{H}_3\text{PtCl}_4$ : monoclinic needles;  $a:b:c = 1.209:1.1094$ ;  $\beta = 113^\circ 35'$ .

Di-chloro-pyridine  $\text{C}_5\text{H}_3\text{Cl}_2\text{N}$  ( $67^\circ$ ). Formed by heating barium pyridine-di-sulphonate with  $\text{PCl}_5$  (Koenigs a. Geigy, *B.* 17, 1833). Volatile with steam. Glistening plates. V. sol. alcohol, sl. sol. water.  $\text{HgCl}_2$  added to the aqueous or alcoholic solution precipitates a double salt which forms long fine needles ( $183^\circ$ ).— $\text{B}'_2\text{H}_3\text{Cl}_2\text{PtCl}_4$ : fine yellow needles.

Di-chloro-pyridine  $\text{C}_5\text{H}_3\text{Cl}_2\text{N}$  ( $73^\circ$ ). Formed, together with other products, by the action of dry chlorine upon dry pyridine. Slender white needles; sol. pyridine and alcohol, insol. water. Has an agreeable aromatic odour (Kaiser, *Am.* 8, 308).

Tri-chloro-pyridine  $\text{C}_5\text{H}_2\text{Cl}_3\text{N}$  ( $50^\circ$ ). Formed, together with di-chloro-pyridine ( $67^\circ$ ) by heating barium pyridine-di-sulphonate with  $\text{PCl}_5$  (Koenigs a. Geigy, *B.* 17, 1833). Volatile with steam. Long flat needles. Sol. alcohol, nearly insol. water.

Tri-chloro-pyridine (?)  $\text{C}_5\text{H}_2\text{Cl}_3\text{N}$  ( $65^\circ$ ). Formed, along with chloro-oxy-pyridine carboxylic acid (q. q.) by treating nicotinic acid with  $\text{PCl}_5$ , and warming the product with  $\text{H}_2\text{SO}_4$  (80 p.c.) (Seyferth, *J. pr.* [2] 34, 261). Long needles (by sublimation); v. sl. sol. water, sol. alcohol, ether, and benzene.

CHLORO-PYRIDINE-CARBOXYLIC ACID  $\text{C}_5\text{H}_4\text{ClNO}_2$ , i.e.  $\text{C}_5\text{H}_4\text{ClN.CO}_2\text{H}$  *Chloro-picolinic acid*. ( $180^\circ$ ). From picolinic acid by treatment with  $\text{PCl}_5$ , the resulting chloro-picolines, including  $\text{C}_5\text{H}_4\text{ClNCOCl}$ , being warmed with  $\text{H}_2\text{SO}_4$  (80 p.c.) (Seyferth, *J. pr.* [2] 34, 249).

*Properties*.—Dendritic needles or prisms, sl. sol. cold water; extracted by ether from aqueous solution.

*Salts*.— $\text{CaA}$ , aq. *Reaction*.—1. HI reduces it to picolinic acid; in presence of phosphorus, picoline is also formed. Chloro-pyridine carboxylic acid

$\text{C}_5\text{H}_4\text{NCl.CO}_2\text{H}$  ( $168^\circ$ ). *Chloro-picolinic acid*. From di-chloro-pyridine carboxylic acid,  $\text{HOAc}$ , and HI at  $160^\circ$  (Ost, *J. pr.* [2] 27, 284). Needles or prisms (containing aq.).— $\text{BaA}$ , 2aq.

Chloro-pyridine-carboxylic acid  $\text{C}_5\text{H}_4\text{NCl.CO}_2\text{H}$  i.e.  $\text{N} \begin{smallmatrix} \text{CH.CCl} \\ \text{CH.CO}_2\text{H} \end{smallmatrix} \text{CH}$  *Chloro-nicotinic acid*. ( $199^\circ$ ). Formed by the action of  $\text{PCl}_5$  on oxy-pyridine-carboxylic acid ( $808^\circ$ )

(Pechmann a. Welsh, *B.* 17, 2392; *C. J.* 47, 145). Sublimable. Glistening plates. Sol. water, alcohol, ether, and acetic acid, sl. sol. benzene. By tin and HCl it is reduced to nicotinic acid.

**Di-chloro-pyridine carboxylic acid**  
 $C_5H_4NCl_2CO_2H$ . *Di-chloro-nicotinic acid*. [138°]. One of the products of the action of warm  $H_2SO_4$  (80 p.c.) on the oily product got from nicotinic acid and PCl<sub>5</sub> (Seyferth, *J. pr.* [2] 34, 262). Clumps of needles (from water).

*Ethyl ether* EtA'. [50°].

**Di-chloro-pyridine carboxylic acid**  
 $C_5H_3Cl_2N.CO_2H$ . *Di-chloro-picolinic acid*. [180°].

**Preparation.**—The mixture of penta- and hexa-chloro-picolines obtained by boiling (10 g.) comenamic acid with (20 g.) dilute (80 p.c.)  $H_2SO_4$  for an hour contains di-chloro-, dichloroxy-, and chloroxy-picolinic acids. The first acid is extracted by chloroform, the other two are separated by means of their lime salts, the calcium chloroxy-picolinate being the more soluble (Ost, *J. pr.* [2] 27, 231). **Properties.**—Slender needles. (containing aq.); sl. sol. cold water, v. sol. hot water and chloroform. Gives no odour with  $FeCl_3$ . Reduced by HI in glacial acetic acid to picolinic acid.

**Salts.**—NaA'. Trapezoidal plates.—KA'. Triangular and trapezoidal plates, often twins.

**Tetra-hydrate**  $C_5H_4Cl_2N.CO_2.H_2O$ . [c. 268°]. From the above by tin and HCl. Laminæ (from water).—B'HCl.

**Di-chloro-pyridine-carboxylic acid**  
 $C_5H_3N(Cl)_2(CO_2H)$  i.e.  $N \begin{smallmatrix} \text{CCl}:\text{CH} \\ \text{CCl}:\text{CH} \end{smallmatrix} C.CO_2H$  (?). [310°]. Formed by heating citrazinic acid with PCl<sub>5</sub> (Behrmann a. Hofmann, *B.* 17, 2691). Colourless plates. Sol. alcohol, v. s. sol. ether, sl. sol. water.—A'Ag: colourless needles.

**TETRA-CHLORO-PYRIMIDINE**  $C_4N_2Cl_4$  i.e.  $CCl=CCl-CCl=CCl$ . [68°]. Formed by heating  $N \equiv CCl-N$  alloxan (1 pt.) with PCl<sub>5</sub> (6 pts.) and POCl<sub>3</sub> (5 pts.) for 8 hrs. at 120°–130°. Colourless pearly plates, of camphor-like smell. Volatile with steam (Ciamician a. Magnaghi, *G.* 16, 173; *B.* 18, 3445).

**TETRA-CHLORO-PYROCATECHIN**  
 $C_6Cl_4(OH)_2$  [1:2:3:4:5:6]. [174°]. Obtained by passing chlorine into a hot, strong solution of pyrocatechin in acetic acid. Colourless needles or thick plates. On oxidation it gives tetra-chloro-o-quinone  $C_6Cl_4O_2$  (Zineke, *B.* 20, 1779).

**PER-CHLORO-PYROCROLL**  $C_6N_2O_4Cl_4$  [above 820°]. Formed, together with the tetra-chloride, by heating pyrocroll (1 g.) with PCl<sub>5</sub> (12 g.) at 220° for 6 hrs. (Ciamician a. Danesi, *G.* 12, 31). Scales. Inaq. acid HOAc. Changed by long boiling into tri-chloro-pyrryl carboxylic acid.

**Tetra-chloride**  $C_6N_2O_4Cl_4$ . Formed as above (O. a. D.). Pearly trichlinic prisms (from HOAc). Sl. sol. cold HOAc.

**Octo-chloride**  $C_6N_2O_4Cl_8$ . [147°]. From per-chloro-pyrocroll and PCl<sub>5</sub> at 250°. Sublimes a little above 100°. Smells like camphor. By reduction with zinc dust and acetic acid it yields tetra-chloro-pyrryl. Heated with water at about 180° it decomposes into (a)-di-chloro-acrylic acid (86°),  $NH_3$ ,  $CO_2$ , and HCl. By boiling with dilute acetic acid it is resolved into di-chloro-

maleimide,  $CO_2$ , and HCl (Ciamician a. Silber, *G.* 13, 320; *B.* 16, 2389).

**TRI-CHLORO-PYROGALLOL**  $C_6Cl_3(OH)_3$ . *Tri-chloro-pyrogalllic acid*. [c. 185°] (H. a. S.). A mixture of pyrogallol (5 g.) and acetic acid (12.5 c.c. of 60 p.c.) is kept cool and dry chlorine is passed in. In half-an-hour tri-chloro-pyrogallol crystallises out (Webster, *C. J.* 45, 205).

**Properties.**—Fine needles (containing 3aq). Resembles tri-bromo-pyrogallol, notably in giving a deep blue colour when baryta is added to its ethereal solution. When anhydrous it melts about 177° (W.); when hydrated it melts at 115° (W.) or 75° (H. a. S.). Sol. water, but slowly decomposed by it. Sol. acetic acid, benzene, chloroform,  $CS_2$ , and  $CCl_4$ . V. sol. alcohol and ether. Reduces ammoniacal  $AgNO_3$  to a mirror.

**Reactions.**—1. *Sodium sulphite* gives a fugitive red colour.—2. Conc.  $HNO_3$  decomposes it. 3. Treated with chloroform saturated with chlorine, it turns wine-red, then effervesces and becomes yellow. On evaporation, crystals of 'leucogallol,'  $C_6H_3Cl_3O_{12}$  2aq (Stenhouse a. Groves, *C. J.* 23, 704), separate. Hence pyrogallol added to chloroform saturated with chlorine is converted into 'leucogallol,' the intermediate tri-chlorinated body being found to very small extent.

**Salts.**— $Ba_2(C_6Cl_3O_3)_2$  6aq (Hantzsch a. Schnitzer, *B.* 20, 2033).— $Cu_2(C_6Cl_3O_3)_2$  6aq.

**Acetyl derivative**  $C_6Cl_3(OAc)_3$ . [123°].

**Needles.**  
 $\beta\gamma$ -**DI-CHLORO-PYROMUCIC ACID**  $C_6H_2Cl_2O_4$  [169°]. Obtained by the action of conc. alcoholic KOH upon pyromucic - ether - tetra - chloride (formed by combination with chlorine in the cold) (Donaro, *G.* 16, 333; Hill a. Jackson, *B.* 20, 252). Felted needles. Sol. hot water, v. sol. alcohol and ether, m. sol. boiling benzene or chloroform, sl. sol. cold benzene or chloroform. Warmed with excess of bromine-water it is converted into mucochloric acid with evolution of  $CO_2$ . By boiling with dilute  $HNO_3$  (1:2) it yields mucochloric acid and di-chloro-maleic acid.

**Salts.**—A'Ba 3aq: fine needles, sl. sol. cold water.—A'Ca 4aq: long needles, sl. sol. cold water.—A'K: rather sparingly soluble small prisms.—A'Ag: fine needles.

*Ethyl ether* ATa: [64°], slender needles.

**Amide**  $C_6HCl_2O.CO.NH_2$ : [176°], felted needles.

#### CHLORO-PYROTARTARIC ACIDS.

**Ita-chloro-pyrotartaric acid**  $C_4H_2Cl_2O_4$  [140°–145°]. (c. 230°). From itaconic acid and conc. HCl at 130 (Swarts, *Z.* 1866, 721). In a current of dry air at 150° it forms an anhydride. Boiling water or alkalis form itaconic acid,  $C_4H_4O_4$ , which rapidly changes to itamic acid,  $C_4H_4O_5$ .

*Diethyl ether* EtA'. (251°).

**Citra-chloro-pyrotartaric acid**  $C_4H_2Cl_2O_4$  [129°]. From citraconic anhydride and cold fuming HCl. Formed also by the union of mesaconic acid with HCl (Fittig, *A.* 188, 51). Tables. Boiling water splits it up into HCl and mesaconic acid. Boiling alkalis form methacrylic acid.

**Ita-di-chloro-pyrotartaric acid**  $C_4H_2Cl_4O_4$  (S).

**Citra-di-chloro-pyrotartaric acid**  $C_4H_2Cl_4O_4$ . From citraconic acid and Cl (Swarts, *J.* 1878,

582; *Bull. Acad. Roy. Belg.* [2] 33, No. 1). On distillation it gives HCl and citraconic anhydride. Boiling water converts it into chloro-citramalic acid  $C_4H_4ClO_4$ . The Na salt when boiled in aqueous solution gives chloro-methacrylic acid.

**TETRA-CHLORO-PYRROL**  $C_4Cl_4NH$ . [110°]. (261°) at 754 mm.

**Formation.**—1. Together with di-chloro-maleic acid and  $NH_3$ , by treating pyrrol with NaOCl. — 2. By reduction of per-chloro-pyrrocoll-octo-chloride with zinc-dust and acetic acid. — 3. By heating di-chloro-maleimide with  $PCl_5$  at 160°. — 4. By reducing with zinc-dust and HCl the per-chloride  $C_4Cl_4N$  which is obtained by heating di-chloro-maleimide with  $PCl_5$  at 200° (Ciamician a. Silber, *B.* 16, 2390; 17, 554, 1743; *G.* 14, 856). Very volatile. Long silky plates. V. sol. alcohol and ether, sl. sol. water. Dissolves in alkalis. The ammoniacal solution gives a white pp. with  $AgNO_3$ . It dissolves in strong  $H_2SO_4$  with an intense reddish-brown colour; on adding a few drops of water this changes to violet, and by further addition of water gives a green pp. which dissolves in KOH with an intense orange colour.

(n). **TRI-CHLORO-PYRROL-CARBOXYLIC ACID**  $C_4Cl_3HNO_2$ , i.e.  $C_4HCl_3N.CO_2H$ .

Prepared by heating per-chloro-pyrrocoll with caustic potash.

$C_4Cl_3N_2O_2 + 2KOH = 2C_4Cl_3HNCO_2K$  (Ciamician a. Danesi, *G.* 12, 34). Long silky needles (containing aq). V. sol. alcohol and ether, sl. sol. water; its solutions give with lead acetate a white pp., and with ferric chloride an intense red colouration. It decomposes with violence at 150°.  $BaA_2$ , aq: scales, m. sol. alcohol, sl. sol. water.

**TRI-CHLORO-PYRUVIC ACID Hydrate**  $CCl_3C(OH)_2CO_2H$ . *Tri-chloro-isoglyceric acid*. [102°]. Prepared by saponification of tri-chloro-acetyl cyanide with HCl (Claisen a. Antweiler, *B.* 13, 1937). Formed also, together with tri-carballic acid, by treating gallic acid, salicylic acid, or phenol with HCl and  $KClO_4$  (Schreder, *A.* 177, 282). Colourless prisms. V. sol. water, alcohol, ether, acetic acid, and acetone; m. sol.  $C_2H_5$  and  $CS_2$ ; insol. petroleum ether. Reduces Fehling's solution and ammoniacal  $AgNO_3$ . Warmed with an alkali it readily splits up into chloroform and an oxalate. —  $A''Ba$ : small soluble prisms. —  $NaA'$  2aq (Hofrichter, *J. pr.* [2] 20, 198).

**Amide**  $CCl_3C(OH)_2CONH_2$ . [127°]. Prepared by the action of cold aqueous HCl on tri-chloro-acetyl cyanide. Colourless crystals. Sol. water, alcohol, ether, and acetone; sl. sol.  $CS_2$ ,  $C_2H_5$ , and  $CHCl_3$ . On heating it loses  $H_2O$  and is converted into a compound of the formula  $C_4Cl_3O_2H_2N$ , which forms small plates or needles of melting-point [218°], which are sublimable and sol. ether, sl. sol. water.

**Nitrile** v. **TRI-CHLORO-ACETYL CYANIDE**.

**$\alpha$ -CHLORO-PYRUVIC ALDEHYDE**  $CH_2.CO.CCO$ .

*Ozim*  $CH_2.CO.CCl(OH)$ : v. **CHLORO-ISONITROSO-ACETONE**.

**CHLORO-QUARTENYLIC ACID** v. **CHLORO-CHROMIC ACID**.

**DL-CHLORO-QUINALDINE** v. **DI-CHLORO-(Py. 3)-METHYL-QUINOLINE**.

**(B. 1)-CHLORO-QUINOLINE**  $C_8H_6ClN$  i.e.

[32°]. (268°). Formed together with the (B. 8)-isomeride by heating *m*-chloro-aniline with glycerine, nitrobenzene, and  $H_2SO_4$  (La Coste, *B.* 18, 2940). Formed also from the corresponding amido-quinoline by Sandmeyer's reaction (Freydl, *M.* 8, 583). Needles or thick glistening prisms. The bichromate forms long yellow needles, [165°]; sol. hot water, sl. sol. cold.

**(B. 3)-Chloro-quinoline**

(c. 257°). Formed, together with the (B. 1)-isomeride, by heating *m*-chloro-aniline with glycerine, nitrobenzene, and  $H_2SO_4$ . Liquid; solidifies in a freezing mixture. Volatile with steam. V. sol. alcohol, ether, and benzene; nearly insol. water. Is probably not quite pure (La Coste, *B.* 18, 2940).

**Salts.** —  $BHCl$ : colourless tables.  $B'H_2Cl.PtCl_2$  2aq: orange silky needles.  $B'H_2Cr_2O_7$ : [119°] fine yellow silky needles; S. 25.

**Methylo-iodide**  $B'MeI$ : [232°]; long yellow needles. On oxidation with  $KMnO_4$  it gives the formyl-derivative of chloro-methyl-amido-benzoic acid, and chloro-methyl-isatin (La Coste a. Bodewig, *B.* 17, 926; 18, 428).

**(B. 2)-Chloro-quinoline**

(256°). Prepared by heating *p*-chloroaniline with glycerine, nitro-benzene, and  $H_2SO_4$ ; the yield is 100 p.c. (La Coste, *B.* 15, 560). Colourless liquid.

**Salts.** —  $BHCl$ : soluble colourless needles.  $(BHCl).PtCl_2$  2aq: yellow crystalline pp.

**Methylo-iodide**  $B'MeI$ : soluble crystalline solid. —  $(B'MeCl)_2.PtCl_2$ : orange crystalline pp.

**(Py. 3)-Chloro-quinoline**  $C_8H_5NCl$ . [38°]. (267°). Formed by the action of  $PCl_5$  on carbostyryl or oxy-carbostyryl (Friedländer a. Ostermayer, *B.* 15, 333). Volatile with steam. Long needles. V. sol. alcohol, ether, benzene and ligroin, nearly insol. water. On heating with water to 120° it gives carbostyryl.

**Chloro-quinoline**  $C_8H_5ClN$ . Formed by heating cynurin with  $PCl_5$  and  $POCl_3$  (Kretschy, *M.* 2, 77). —  $B'H_2PtCl_2$  2aq.

**(Py. 1,3)-Di-chloro-quinoline**, called ( $\gamma$ ),

[67°]. (281°). Formed by the action of  $PCl_5$  on (Py. 1,3)-di-oxy-quinoline (Friedländer a. Weinberg, *B.* 15, 2683) or on ( $\gamma$ )-chloro-carbostyryl (Baeyer a. Bloem, *B.* 15, 2150). Slender needles; sol. alcohol, ether, and benzene, nearly insol. water.

**(B. 1,4)-Di-chloro-quinoline**

[93°]. Prepared by heating (3:6:1)-di-chloro-aniline with glycerine, nitro-benzene, and  $H_2SO_4$  (La Coste, *B.* 15, 561). Volatile undecomposed. Colourless needles or tables. Sol. alcohol and ether.

(B. 2:4)-Di-chloro-quinoline  
 $\text{ClCH}:\text{CH}:\text{C}:\text{CH}:\text{OH}$   
 [104°]. Prepared by heating  
 $\text{CH}_2\text{CCL}:\text{CN}:\text{CH}$   
 (4:2:1)-di-chloro-aniline with glycerin, nitro-benzene, and  $\text{H}_2\text{SO}_4$  (La Coste, B. 15, 561). Long fine colourless needles. Sol. alcohol.

(Py. 2,8)-Di-chloro-quinoline  $\text{C}_8\text{H}_5\text{Cl}_2\text{N}$  i.e.  
 $\text{C}_8\text{H}_5\text{CH}:\text{CCL}:\text{N}:\text{CCL}$  [105°]. Weak base. Prepared by treating hydro-carbostyryl with  $\text{PCl}_5$  and distilling the product with steam; the yield is 20-30 p.c. (Baeyer, B. 12, 1920). Insol. water, sol. alcohol, ether, and  $\text{C}_6\text{H}_6$ . On reduction with HI it gives quinoline.

Tri-chloro-quinoline  $\text{C}_8\text{H}_3\text{Cl}_3\text{N}$  [108° uncor.]. Formed by heating phenyl-malonamic acid (malonanilidic acid)  $\text{CO}_2\text{H}:\text{CH}_2:\text{CO}:\text{NHPh}$  with benzene and  $\text{PCl}_5$  (Rügheimer, B. 17, 736). Long colourless needles. Volatile with steam. Sol. alcohol, benzene, and ligroin. By heating with an acetic acid solution of HI at 240° it is reduced to quinoline.

Tri-chloro-quinoline  $\text{C}_8\text{H}_3\text{Cl}_3\text{N}$  [161°]. From di-chloro-carbostyryl and  $\text{PCl}_5$  (Friedländer a. Weinberg, B. 15, 1425). Slender needles (from alcohol); slightly volatile with steam.

Tri-chloro-quinoline  $\text{C}_8\text{H}_3\text{Cl}_3\text{N}$  [211°]. Formed by acting on the borate of (B. 4)-chloro-quinoline with bleaching powder solution (Emhorn and Lauch, A. 243, 361). Needles (from acetic ether).

(Py. 2)-CHLORO-ISOQUINOLINE  $\text{C}_8\text{H}_5\text{ClN}$   
 i.e.  $\text{C}_8\text{H}_5\text{CH}:\text{CCL}:\text{CH}:\text{N}$  [45°-48°]. (280°) at 753 mm. Formed by heating the di-chloro-derivative [128°] with HI and P at 170°. By more prolonged action at 200° it is completely di-chlorinated to isoquinoline. Long colourless needles. Weak base (Gabriel, B. 19, 1655, 2356).

(Py. 2:4)-Di-chloro-isoquinoline  $\text{C}_8\text{H}_3\text{Cl}_2\text{N}$  i.e.  
 $\text{C}_8\text{H}_3\text{CH}:\text{CCL}:\text{CCL}:\text{N}$  [123°]. (306°). Formed by heating the imide of phenyl-acetic-*o*-carboxylic acid  $\text{C}_6\text{H}_4\text{CH}_2:\text{CO}:\text{NH}$  with  $\text{POCl}_3$  (8 pts.) at 150°-170°. Very long flat needles (from alcohol). V. sol. chloroform, benzene, ether, and hot alcohol. Slowly volatilises with steam. By HI and P it is first reduced to the mono-chloro-derivative and finally to isoquinoline (Gabriel, B. 19, 1655, 2356).

#### CHLORO-QUINONE $\text{C}_8\text{H}_5\text{ClO}_2$ [57°]

**Formation.**—1. By distilling cupric quinate (25 g.) with  $\text{NaCl}$  (60 g.),  $\text{MnO}_2$  (40 g.),  $\text{H}_2\text{SO}_4$  (100 g.), and water (170 g.) (Städeler, A. 69, 300). 2. By oxidation of chloro-hydroquinone with  $\text{CrO}_3$  (Levy a. Schultz, A. 210, 144; B. 13, 1428). 8. By adding aqueous  $\text{K}_2\text{CrO}_4$  to a slightly acid solution of chloro-amido-phenol sulphate (Kollrepp, A. 234, 14).

**Properties.**—Long yellow trimetric needles;  $a:b:c = 47:1:1.71$ ; v. sol. ether, m. sol. alcohol, HOAc, and hot water. Turns the skin purple. Reduced by  $\text{SO}_2$  to chloro-hydroquinone.

**Reactions.**—1. When mixed with *m*-nitro-aniline in benzene solution, dark green crystals

of  $\text{C}_8\text{H}_5\text{Cl}(\text{O})_2(\text{NH}_2\text{C}_6\text{H}_4\text{NO}_2)$ , separate. This breaks up into its constituents even on recrystallising from benzene (Niemeyer, A. 228, 322). 2. *p*-Toluidine forms, in the same way, white plates [90°] ( $^*\text{C}_8\text{H}_5\text{Cl}(\text{OH})_2(\text{C}_6\text{H}_4\text{N})_2$ ).

(a)-Di-chloro-quinone  $\text{C}_8\text{H}_3\text{Cl}_2\text{O}_2$  [5:2:4:1]. [159°]

**Formation.**—1. One of the products of the distillation of cupric quinate with  $\text{MnO}_2$ ,  $\text{NaCl}$ , and  $\text{H}_2\text{SO}_4$  (Städeler, A. 69, 300).—2. From benzene and  $\text{Cl}_2\text{O}$  (Carius, A. 143, 315).—3. Together with chloro-benzene and tri-chloro-phenomalic acid, by dissolving benzene (48 g.) in  $\text{H}_2\text{SO}_4$  (300 g.), diluting with water (150 g.), and, after cooling, adding more benzene (100 g.) and  $\text{KClO}_4$  (150 g.). The mixture is left to itself for a week (C.).—4. By the oxidation of (a)-di-chloro-hydroquinone with conc.  $\text{HNO}_3$  (Levy a. Schultz, B. 13, 1428; A. 210, 150).—5. By oxidation of di-chloro-*p*-phenylene-diamine [164°] with  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  (Möhlau, B. 19, 2010).—6. By oxidation of *p*-di-chloro-aniline with  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$ .—7. From quinone by two alternate treatments with  $\text{HCl}$  and with  $\text{FeCl}_3$  (Levy, B. 18, 2366).—8. By adding  $\text{K}_2\text{CrO}_4$  to a solution of di-chloro-amido-phenol sulphate (Kollrepp, A. 234, 15).

**Properties.**—Yellow monoclinic crystals;  $a:b:c = 1:15:1.2:21$ ;  $\beta = 56^\circ 26'$  (Grünling);  $abc = 1:09:1:1:84$ ;  $\beta = 89^\circ 11'$  (Fock, Z. K. 7, 40). Sol. ether and chloroform, nearly insol. alcohol, insol. water. Volatile with steam.  $\text{SO}_2$  reduces it to di-chloro-hydroquinone [172°].

**Reactions.**—1. Aniline in acetic acid solution, in presence of some  $\text{HCl}$ , forms blue plates of the anilide  $\text{C}_8\text{H}_4\text{Cl}_2\text{O}_2(\text{NPhH})$  [5:2:4:1:3] [180°], which dissolves in conc.  $\text{H}_2\text{SO}_4$ , giving a deep-blue liquid (Niemeyer, A. 228, 332).—2. If, after warming with aniline, the hot solution is treated with HOAc, lustrous brown plates of the di-anilide  $\text{C}_8\text{H}_3\text{Cl}_2\text{O}_2(\text{NPhH})_2$  [290°] are formed. This is the so-called 'chloranil-anilide' obtained from tetra-chloro-quinone and aniline.—3. *m*-Nitro-aniline forms dark green crystals of  $\text{C}_8\text{H}_3\text{Cl}_2\text{O}_2(\text{NH}_2\text{C}_6\text{H}_4\text{NO}_2)_2$  [110°] which may be crystallised from hot benzene (Niemeyer, A. 228, 322).—4. *p*-Toluidine forms a crystalline compound [116°] ( $^*\text{C}_8\text{H}_5\text{Cl}_2\text{O}_2(\text{C}_6\text{H}_4\text{N})_2$ ).

( $\beta$ )-Di-chloro-quinone  $\text{C}_8\text{H}_3\text{Cl}_2\text{O}_2$  [2:6:1:4]. [120°]

**Formation.**—1. By oxidation of trichloro-phenol with  $\text{HNO}_3$ , or a mixture of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  (Faust, Z. 1867, 727; Weselsky, B. 3, 646; Levy a. Schultz, B. 13, 1428; Guareschi a. Daccamo, B. 18, 1170).—2. In small quantity by treating di-chloro-nitro-phenol [125°] with  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  (Armstrong, Z. 1871, 521).—3. By oxidation of di-chloro-*p*-phenylene-diamine with  $\text{CrO}_3$  (Levy, B. 18, 1445). Yellow trimetric crystals,  $a:b:c = 7:127:1:2:027$ . V. sol. boiling alcohol, v. sl. sol. hot water. Turns the skin brown. Readily sublimates. Volatile with steam.  $\text{SO}_2$  forms ( $\beta$ )-di-chloro-hydroquinone [158°].

**Reactions.**—1. Aniline (1 mol.) in alcoholic solution containing a little  $\text{HCl}$ , forms bluish-violet needles or plates of the anilide  $\text{C}_8\text{H}_3\text{Cl}_2\text{O}_2(\text{NPhH})$  [164°]. This is sol. alcohol and ether, and gives a violet-blue solution in conc.  $\text{H}_2\text{SO}_4$  (Niemeyer, A. 228, 332).—2. Excess of aniline added to an alcoholic or acetic acid

solution forms  $C_6HClO_2(NPhH)_2$  (2:1:4:6:3) [263°]. This forms lustrous brown plates, sl. sol. alcohol and benzene, m. sol. hot  $HOAc$  (N.).—  
 3. *m*-Nitro-aniline forms glittering dark green

*p*-Toluidine forms, in the same way, slender needles [73°] ( $C_6H_4Cl_2(OH)_2, C_6H_4N_2$ ).  
 Tri-chloro-quinone  $C_6HCl_3O_2$ . (163°).

**Formation.**—1. By chlorinating quinone (Woskresensky, *J. pr.* 18, 419).—2. By boiling quinic acid with  $MnO_2$  and  $HCl$  (Städeler, *A.* 69, 818).—3. Together with tetrachloroquinone, by treating phenol with  $KClO_2$  and aqueous  $HCl$  (Graebe, *A.* 146, 9; Stenhouse, *C. J.* 21, 141).—4. From benzene and  $CrO_3Cl_2$  (Carstanjen, *B.* 2, 633).—5. By dropping sodium hypobromite solution slowly into a solution of the hydro-chloride of tri-chloro-*p*-amido-phenol; the pp. is recrystallised from alcohol (M. Andresen, *J. pr.* [2] 28, 422).—6. From *p*-amido-phenol (*q. v.*) and bleaching powder (Schmitt a. Andresen, *J. pr.* [2] 23, 436).

**Properties.**—Yellow prisms. May readily be sublimed. Does not colour the skin. Insol. water, sol. hot alcohol, v. sol. ether. Dilute aqueous  $KOH$  dissolves it, forming di-chloro-di-oxy-quinone (chloranilic acid).

**Reactions.**—1. With alcoholic solution of aniline it gives glittering plates of di-chloro-quinone-di-anilide:  $2C_6HClO_2 + 3PhNH_2 = C_6(NPhH)_2Cl_2O_2 + C_6HCl_2(OH)_2 + PhNH_2.HCl$ . This substance crystallises from benzene in tablets which have a bluish lustre (M. Andresen, *J. pr.* [2] 28, 423).—2. Aniline (1 mol.) forms lustrous leaflets of  $C_6HClO_2(NPhH)_2$ . This forms a blue solution in conc.  $H_2SO_4$  (Schultz, *B.* 10, 1792; *A.* 210, 180).—3. Aniline treated with excess of the quinone forms blue plates of  $C_6Cl_2O_2(NPhH)_2$  (Niemeier, *A.* 228, 332).—4. *m*-Nitro-aniline forms lustrous dark-green prisms of  $C_6HCl_2O_2(NH_2.C_6H_4.NO_2)_2$  [108°] (N.).—5.  $PCl_5$  at 190° gives  $C_6Cl_4$ .—6.  $AcCl$  gives the di-acetyl derivative of tetra-chloro-hydroquinone.—7. Boiling conc. aqueous  $HCl$  forms tetra-chloro-hydroquinone.

**Tetra-chloroquinone**  $C_6Cl_4O_2$ .

**Formation.**—1. By the action of a mixture of  $KClO_2$  and  $HCl$  on quinone, aniline, phenol, tri-chloro-phenol, di-nitro-phenol, tri-nitro-phenol, salicin, salicylic acid, isatin, quinic acid, tyrosine, *m*-amido-benzoic acid, &c. (Hofmann, *A.* 62, 55; Hesse, *A.* 114, 303; Städeler, *A.* 69, 826; 116, 99; Stenhouse, *A.* 78, 4; *A. Suppl.* 6, 209; Erlenmeyer, *J.* 1861, 404; *N. Jahr. Pharm.* xvi. 292).—2. By passing chlorine into an alcoholic solution of chloro-isatin (Erdmann, *A.* 48, 809).—3. From penta-chloro-phenol and fuming  $HNO_3$  (Merz a. Weith, *B.* 5, 460).—4. Prepared by oxidation of tetrachlorohydroquinone (Levy a. Schultz, *B.* 13, 1429).—5. By heating trichloroquinone (5 g.) for 12 hours with fuming  $HCl$  (100 a.c.). The product is oxidised by strong  $HNO_3$  and recrystallised from alcohol (Andresen, *J. pr.* [2] 28, 425).—6. From *s*-tetra-chloro-benzene [137°] and fuming  $HNO_3$  (Beilstein a. Kurbatoff, *A.* 192, 286).—7. From pherol and chloride of iodine (Stenhouse, *C. J.* 23, 6).—8. From di-chloro-di-oxy-quinone and  $PCl_5$ .

**Properties.**—Pale yellow, lustrous scales. Monoclinic;  $a:b:c = 1:62:1:300$ ;  $\beta = 78^\circ 56'$  (Fork, *Z. K.* 7, 40). When heated gently it sublimes

without melting. Insol. water, v. sl. sol. cold alcohol, m. sol. ether. Not attacked by  $HNO_3$  by  $HCl$ , or by boiling conc.  $H_2SO_4$ .  $SO_2$  reduces it to tetra-chloro-hydroquinone. Boiling  $HCl$  or  $HBr$  also reduces it to the same body.

**Reactions.**—1. Conc. aqueous  $KHSO_5$  forms potassium thiochromate  $C_6(OH)O_2(SO_3K)(SO_3K)_2$ . Dilute  $KHSO_5$  gives  $C_6Cl_2(OH)_2(SO_3K)_2$ .

2. Aqueous  $KOH$  forms a purple solution containing  $C_6Cl_2(OK)_2O_2$ .—3.  $AcCl$  at 170° gives  $Cl$  and  $C_6Cl_2(OAc)_2$  (Graebe, *A.* 146, 12).—4.  $PCl_5$  at 180° gives  $C_6Cl_4$ .—5. Aqueous  $NH_3$  gives  $C_6Cl_2(NH_2)_2(OH)_2$  (Erdmann, *J. pr.* 22, 287; Laurent, *A. Ch.* [3] 8, 493).—6. Alcoholic  $NH_3$  forms  $C_6Cl_2(NH_2)_2O_2$ .—7. An alcoholic solution of aniline reacts thus:  $C_6Cl_2O_2 + 4NPhH_2 = C_6Cl_2(NPhH)_2O_2 + 2NPhH_2.HCl$  (Andresen, *J. pr.* [2] 28, 426).—8. *m*-Nitro-aniline forms almost black crystals of  $C_6Cl_2O_2(NH_2.C_6H_4.OH)_2$  (Niemeier, *A.* 228, 332).—9. A hot aqueous solution of  $NaNO_2$  converts it into nitranilic acid (Nef, *B.* 20, 2027).—10. By warming an acetic acid solution of *p*-amido-xylenol (4 pts.) with chloranil (1 pt.) there is formed a colouring matter  $C_{12}H_8N_2O_6$ . Sol. alcohol, ether, benzene, and acetone, insol. water. Dissolves in alkalis with a blue colour, in conc.  $H_2SO_4$  with a greenish-blue. By  $CrO_3$  it is oxidised to *p*-xyloquinone (Sutkowski, *B.* 20, 980).

Tetra-chloro-o-quinone  $C_6Cl_4O_2$  (1:2:3:4:5:6). [132°]. Obtained by oxidation of tetra-chloro-pyrocatechin with  $HNO_3$ , or directly by passing chlorine into a hot acetic acid solution of pyrocatechin until it assumes a deep reddish-yellow colour. Dark-red crystals. V. sol. acetic acid (Zincke, *B.* 20, 1779).

***p*-DI-CHLORO-QUINONE-DI-CARBOXYLIC.**

**ETHYL-ETHER**  $C_6Cl_2O_2(CO_2Et)_2$  [1:4:2:5:3:6].

[195°]. Formed by the action of chlorine upon quinone-di-hydro-di-carboxylic ether (di-oxy-terephthalic ether) or upon succinyl-succinic ether, suspended in alcohol. Greenish-yellow needles. Sol. acetic acid and chloroform, sl. sol. alcohol and ether. The  $Cl$  atoms are extremely mobile: thus by very dilute  $NaOH$  it is dissolved with formation of di-oxy-quinone-di-carboxylic ether; by  $NH_3$  or amines it is readily converted into di-amido-quinone-di-carboxylic ether or its alkyl-derivatives. It is reduced by zinc-dust and acetic acid to the colourless di-chloro-hydroquinone-di-carboxylic ether (di-chloro-di-oxy-terephthalic ether, *q. v.*) (Hantzsch a. Zeckendorf, *B.* 20, 1310).

**Dihydride**  $C_6H_2O_2Cl_2(CO_2Et)_2$ . The colourless di-chloro-di-oxy-terephthalic ether becomes intense greenish-yellow when melted, changing to the tautomeric dihydride of tetra-chloro-quinone di-carboxylic ether. The colourless body dissolves in benzene, chloroform, and conc.  $SO_2H_2$  with an intense greenish-yellow colour, whereas the solution in alcohol is colourless; the formation of an alcoholate (with  $2HOEt$ ) appears in the latter case to hinder the tautomeric change. This alcoholate can be dissociated by adding benzene to the colourless alcoholic solution when it turns yellow (Hantzsch a. Herrmann, *B.* 21, 1757).

**CHLORO-QUINONE-CHLORIMIDE**

$C_6H_2Cl_2 \begin{matrix} \swarrow NCl \\ \searrow O \end{matrix}$  [2°]. Formed by adding bleach.

ing powder to a solution of the hydro-chloride of chloro-*p*-amido-phenol at 0° (Kollrepp, *A.* 234, 16). Yellow needles (from alcohol or HOAc).

**Di-chloro-quinone-chlorimide**  
 $C_6H_3Cl_2 \left\langle \begin{smallmatrix} NCl \\ O \end{smallmatrix} \right\rangle$  [6:2:1]. [87°]. From di-chloro-*p*-amido-phenol hydrochloride by treatment in the solid with bleaching powder (Kollrepp, *A.* 234, 19). Yellow needles; sol. alcohol; decomposes at 170°.

**Di-chloro-quinone di-chlorimide**  
 $C_6H_2Cl_4 \left\langle \begin{smallmatrix} NCl \\ NCl \end{smallmatrix} \right\rangle$ . Prepared by the action of chloride of lime on an acid solution of *p*-phenylene-diamine (Krause, *B.* 12, 47). White needles. Insol. cold water, sol. hot water, alcohol ether,  $C_6H_6$ , &c. Neutral body. On reduction it gives *p*-phenylenediamine. By boiling with HCl it gives tetrachlorophenylene diamine. Bromine in acetic acid solution converts it into di-chloro-dibromo-quinone.

**Tri-chloro-quinone chlorimide**  
 $C_6HCl_3 \left\langle \begin{smallmatrix} O \\ NCl \end{smallmatrix} \right\rangle$ . [118°].

**Preparation.**—By stirring a slightly acid solution of tri-chloro-*p*-amido-phenol (*q. v.*) with a solution of bleaching powder (Schmitt & Andresen, *J. pr.* [2] 23, 438; 28, 427).

**Properties.**—Long yellowish needles, with rough ends. V. sol. hot alcohol, ether and benzene, less sol. cold water. When melted it forms a light-brown liquid, which boils at 185° with decomposition.

**Reactions.**—1. Aniline (3 equivalents) forms di-chloro-quinone dianilide:

But when excess of aniline (5 mols.) is added to saturated alcoholic solution of the chloro-imide at 60° a violent reaction occurs, and the crystals which ultimately separate contain another body also. This is *di-phenyl-di-amido-chloro-quinone-chloro-phenyl-imide*,  $C_6Cl(NPhH)_2H \left\langle \begin{smallmatrix} NPh \\ O \end{smallmatrix} \right\rangle$ .

[195°]. It forms long elastic needles (from alcohol). It is sol. ether, benzene, glacial acetic acid and  $CS_2$ . (a) Nitrous acid passed into its alcoholic solution produces an unstable nitroso-derivative. (b) It is not affected by boiling aqueous potash, but is converted by alcoholic potash into glittering red needles of  $C_6Cl(NPhH)_2H(OH)(NPhNa)$ . But this compound is so unstable that alcohol reconverts it into the original body with simultaneous formation of NaOEt. (c) Fuming HCl mixed with alcohol reacts thus:

2. The ethyl derivative of *o*-amido-phenol ( $C_6H_4(OEt)(NH_2)$ ) acts upon tri-chloro-quinone-chlorimide in a similar way, forming di-ethoxy-di-phenyl-di-chloro-quinone:  $C_6Cl_2(NH.C_2H_5.OEt)_2$ . This body melts about [200°], crystallises from alcohol in glittering brown prisms, and is thrown down as a grass-

green pp. when water is added to its alcoholic solution. It is not dissolved by alkalis, but forms a deep-blue solution with  $H_2SO_4$ .—3. *Di-methyl-aniline* in warm alcoholic solution

chloro-quinone-di-methyl-amido-phenyl-imide is almost insoluble in water. It crystallises from alcohol in golden-green needles which have a blue streak (when scratched) and are very tough. It is v. sol. ether, benzene, and chloroform. It is reduced by  $SO_2$  to di-methyl-amido-phenyl-tri-chloro-phenol,  $C_6Cl_3H(OH).NH.C_6H_5.NMe_2$ . This latter is insoluble in water, readily soluble in ether, benzene and chloroform. Recrystallised from alcohol, it melts at [139°], but its alcoholic solution is readily oxidised by the air to the preceding imide. **Salt.**— $B \cdot HCl$ . The *sulphonic acid* of this base  $C_6Cl_3(SO_3H)(OH).NH.C_6H_5.NMe_2$  is formed along with the base itself by the action of  $SO_2$  on tri-chloro-quinone-di-methyl-amido-phenyl-imide. It crystallises in pearly plates when HCl is added to its solution in  $NH_3$ . It is insoluble in water, alcohol, ether and benzene.  $BaCl_2$  added to a solution of the acid in an alkali gives a pp. which may be recrystallised from hot water (Schmitt & Andresen, *J. pr.* 132, 426).—4. Aqueous HCl acts upon tri-chloro-quinone-chloro-imide as follows:

**Di-chloro-quinone-di-chlorimide**

$C_6H_2Cl_4 \left\langle \begin{smallmatrix} NCl \\ NCl \end{smallmatrix} \right\rangle$  [5:2:4:1]. [135°]. Formed by treatment of a dilute HCl solution of di-chloro-*p*-phenylene diamine [164°] with chloride of lime (Möhlau, *B.* 19, 2011). Colourless prisms (from ether). Sublimable.

**CHLORO-RESORCIN**  $C_6H_3Cl(OH)_2$ . [89°]. [256°].

**Preparation.**—Sulphuryl chloride (1½ pts.) is added gradually to a solution of resorcin (1 pt.) in dry ether (3 pts.).  $C_6H_3(OH)_2 + SO_2Cl_2 = HCl + SO_2 + C_6H_3Cl(OH)_2$ .

**Properties.**—Sol. water, alcohol, ether, benzene, and  $CS_2$ . Crystallises with difficulty. Its aqueous solution is feebly acid to litmus. Ammonia turns its aqueous solution first yellow, then green; acids decolourise this liquid.  $FeCl_3$  gives a bluish-violet colour. Ammoniacal silver solution is reduced on boiling (G. Reinhard, *J. pr.* 125, 322). Bromine gives chloro-di-bromo-resorcin (*q. v.*).

**Benzoyl derivative**  $C_6H_3Cl(OBz)_2$ . [98°]. Hexagonal crystals (from alcohol). Insol. water.

**Di-methyl ether**  $C_6H_3Cl(OMe)_2$ . [118°]. From di-methyl resorcin in HOAc and Cl (Hönig, *B.* 11, 1039). Long needles (from alcohol). Insol. cold HOAc, v. sol. ether.

**Di-chloro-resorcin**  $C_6H_3Cl_2(OH)_2$ . [77°]. [349°]. Formed by stirring, and finally melting, a mixture of sulphuryl chloride (2½ pts.) with

resorcin (1 pt.). Purified by sublimation. The yield is 80 p.c. (G. Reinhard, *J. pr.* [2] 17, 828).

**Properties.**—V. sol. water, alcohol, ether, benzene, and  $\text{CS}_2$ . Aqueous solutions are feebly acid to litmus, reduce boiling ammoniacal silver nitrate, and give a bluish-red colour with  $\text{FeCl}_3$ .

**Reactions.**—1. With bromine-water it gives di-chloro-bromo-resorcin (q. v.).—2. With  $\text{ClSO}_3\text{H}$  it forms a crystalline insoluble powder  $\text{C}_6\text{H}_3\text{Cl}_2\text{SO}_3$ , probably the anhydride of di-chloro-resorcin sulphonic acid ( $\text{C}_6\text{H}_3\text{Cl}_2(\text{SO}_3\text{H})\text{OH}$ ), O.

**Benzoyl derivative**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{OBz})_2$  [127°].

**Di-methyl ether**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{OMe})_2$ . From di-methyl-resorcin in HOAc by Cl (Hönig, *B.* 11, 1039). Oil; decomposed at 140°.

**Sulphonic acid**  $\text{C}_6\text{H}_3\text{Cl}_2(\text{OH})(\text{SO}_3\text{H})$ . A white powder, sol. water and alcohol. Formed by dissolving its anhydride (see above) in  $\text{K}_2\text{CO}_3$ , acidifying, evaporating, and extracting with alcohol. *Salt*.—BaA'.

Tri-chloro-resorcin  $\text{C}_6\text{H}_3\text{Cl}_3(\text{OH})_2$  [83°] and [78°].

**Preparations.**—1. By digesting resorcin with sulphuryl chloride (6 pts.) for 3 hours at 100°. Crystallised from water. The yield is 30 p.c.—2. Resorcin (20 g.) dissolved in water (80 g.) is kept cool and treated with chlorine gas until the red colour, which first appears, is nearly gone. The liquid is heated to 70°, filtered from resin and allowed to deposit crystals.—3. By chlorinating a solution of resorcin (100 g.) in HOAc (250 g.) (Benedikt, *M.* 4, 224).

**Properties.**—Silky needles, sl. sol. cold water, v. sol. hot water, alcohol, and ether. When purified by sublimation it is yellow and melts at [73°]. Its solutions resemble those of chloro-resorcin in behaviour towards litmus and  $\text{AgNO}_3$ . With  $\text{FeCl}_3$  it gives a wine-red colour on warming (Reinhard, *J. pr.* [2] 17, 336). Oxidised by  $\text{K}_2\text{FeO}_4$  to  $\text{C}_6\text{H}_2\text{Cl}_3\text{O}_5$  [60°] (Stenhouse a. Groves, *B.* 13, 1807).

**Benzoyl derivative**  $\text{C}_6\text{H}_3\text{Cl}_3(\text{OBz})_2$  [133°]. Glittering prisms (from alcohol).

Tri-chloro-resorcin  $\text{C}_6\text{H}_3\text{Cl}_3(\text{OH})_2$  [69°]. Formed by the action of  $\text{KHSO}_4$  on penta-chloro-resorcin (Claassen, *B.* 11, 1441). White needles. V. sol. alcohol, ether, and hot water. May be identical with the preceding.

**Tetra-chloro-resorcin.**—**Di-propyl ether**  $\text{C}_6\text{H}_2\text{Cl}_4(\text{OC}_3\text{H}_7)_2$ . From di-propyl-resorcin and Cl (Kariot, *B.* 13, 1678). Liquid; decomposed at 100°. Sol. alcohol and HOAc; sl. sol. water.

**Penta-chloro-resorcin**  $\text{C}_6\text{HCl}_5(\text{OH})(\text{OCl})$  or  $\text{C}_6\text{H}_2\text{Cl}_5(\text{O})(\text{OH})$  [92-5°]. Formed by adding alternately in small portions  $\text{KClO}_4$  (5 pts.) and a solution of resorcin (2 pts.) in HCl (8 pts.) to pooled HCl (40 pts. of S.G. 1.17) (Stenhouse, *Pr.* 20, 78). Plates or flat prisms (from  $\text{CS}_2$ ). V. sol.  $\text{CS}_2$ , and benzene, v. e. sol. alcohol and ether. Changes in the air into a modification melting at 65° (Liebermann a. Dittler, *A.* 169, 265). Hot water effects the same change.

**Reactions.**—1. Dissolves in a cold solution of potassium bisulphite with evolution of heat and formation of tri-chloro-resorcin [90°] (Claassen, *B.* 11, 1441). HI appears also to form tri-chloro-resorcin (Stenhouse, *C. N.* 23, 230).—2. Unlike penta-bromo-resorcin, it is not affected by aldehyde and formic acid.

**CHLORO-RETENE v. RETENIN.**

**CHLORO-ROSANILINE v. DI-CHLORO-TRI-AMIDO-TRI-PHENYL-CARBINOL.**

**CHLORO-SALICIN v. SALICIN.**

**CHLORO-SALICYLIC ACID v. CHLORO-O-OXY-BENZOIC ACID.**

**CHLORO-SALICYLOL v. CHLORO-O-OXY-BENZOIC ALDEHYDE.**

**CHLORO-SALIGENIN v. CHLORO-OXY-BENZYL ALCOHOL.**

**PER-CHLORO-SEBACIC ACID**  $\text{C}_{10}\text{H}_6\text{Cl}_{10}\text{O}_4$ .

**Per-chloro-butyl ether**  $\text{C}_{10}\text{H}_6\text{Cl}_{10}(\text{C}_4\text{H}_9\text{O})_2$  [172°]. (200°). From butyl sebacate and Cl in sunshine (Gehring, *C. R.* 104, 1624). Hexagonal prisms.

**Per-chloro-isoamyl ether**

$\text{C}_{15}\text{H}_{10}\text{Cl}_{15}(\text{C}_5\text{H}_{11}\text{O})_2$  [179°]. From isoamyl sebacate and Cl in sunshine (G.). Tough trimetric prisms (by sublimation); volatile with steam. Insol. water, sl. sol. alcohol, v. sol. ether, benzene, chloroform, and ligroin.

**CHLORO-STEARIC ACID**  $\text{C}_{18}\text{H}_{10}\text{Cl}_{18}\text{O}_4$ . From stearic acid and Cl at 100° (Hardwick, *C. J.* 2, 232).

**CHLORO-STILBENE v. CHLORO-DI-PHENYL-ETHYLENE.**

**CHLORO-STRYCHNINE v. STRYCHNINE.**

**(ω)-CHLORO-STYRENE**  $\text{C}_6\text{H}_4\text{CH}(\text{CHCl})_2$  (196°) at 716 mm.

**Formation.**—1. By distilling styrene dichloride  $\text{C}_6\text{H}_4\text{CHClCH}_2\text{Cl}$  either alone or over CaO (Byth a. Hofmann, *A.* 53, 310).—2. By heating  $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{CHCl}_2$  with alcoholic KOH at 120° (Forrer, *B.* 17, 983).

**Properties.**—Liquid, with pungent odour. Conc. alcoholic KOH followed by distillation with water gives phenyl-acetic aldehyde. KCy gives the nitrile of phenyl-succinic acid (Rügheimer, *B.* 14, 428).

**(α)-Chloro-styrene**  $\text{C}_6\text{H}_5\text{CHClCH}_2$  (199°). S.G.  $d_4^{25}$  1.112.

**Formation.**—1. By treating cinnamic acid with KOCl or with HCl and potassium chlorate (Stenhouse, *A.* 55, 1; 57, 79).—2. By heating  $\text{C}_6\text{H}_5\text{CHClCH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$  with water at 210° (Glaser, *A.* 154, 166).—3. From  $\text{C}_6\text{H}_5\text{CCl}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$  and alcoholic KOH (Friedel, *C. R.* 67, 1192; Erlenmeyer, *B.* 12, 1609).—4. By neutralising a solution of  $\text{C}_6\text{H}_5\text{OHCHClCHClCO}_2\text{H}$  (Erlenmeyer, *B.* 14, 1867).

**Properties.**—Liquid, with the odour of hyacinths. Does not so readily give up its Cl as the preceding. But by heating with water acetophenone may be formed (Erlenmeyer, *B.* 14, 823).

**ω-Di-chloro-styrene**  $\text{C}_6\text{H}_4\text{CHClCHCl}$  (221°). From  $\text{C}_6\text{H}_5\text{COCH}_2\text{CH}_2\text{Cl}$  and  $\text{PCl}_5$  (Dyckerhoff, *B.* 10, 126, 533).

**CHLORO-SUBERANE CARBOXYLIC ACID**  $\text{C}_{12}\text{H}_{12}\text{ClO}_4$ . From the corresponding oxy-acid and  $\text{HCl}$ . Oil; sol. alcohol and ether. KOH gives suberene carboxylic acid  $\text{C}_{12}\text{H}_{14}\text{O}_4$  (Dale a. Schorlemmer, *C. J.* 39, 539).

**CHLORO-SUBERIC ACID**  $\text{C}_{12}\text{H}_{10}\text{ClO}_4$ . From suberic acid and Cl (Bauer a. Gröger, *M.* 1, 510; 4, 841). Syrup; sol. water, v. e. sol. ether.

**CHLORO-SUBERONIC ACID**  $\text{C}_{12}\text{H}_{10}\text{ClO}_5$ . From oxy-suberic acid and conc. HCl at 180° (Spiegel, *A.* 211, 119). Oil; v. sol. alcohol and ether. Converted by sodium amalgam into suberic acid. Boiling NaOH aq forms  $\text{C}_{12}\text{H}_{12}\text{O}_4$ .

**CHLORO-SUCCINIC ACID**  
 $\text{CO}_2\text{H}.\text{CH}_2.\text{CHCl}.\text{CO}_2\text{H}$ . [152°]. Prepared by heating fumaric acid with a solution of HCl in glacial acetic acid (Anschütz a. Bennert, *B.* 15, 642). Crystalline solid. Sol. water and acetic acid, sl. sol. chloroform.

**Anhydride**  $\begin{array}{c} \text{CHCl.CO} \\ | \\ \text{CH}_2.\text{CO} \end{array}$   $\begin{array}{c} >\text{O} \\ // \end{array}$  [41°]. (130° at 15 mm.). Prepared by heating the acid with acetyl chloride. Formed as a by-product, when maleic anhydride is produced by heating fumaric acid with  $\text{AcCl}$  for 8 hrs. at 140° (Perkin, *C. J.* 41, 269). Crystalline solid. Sol. chloroform. On heating it decomposes into maleic anhydride and HCl.

Di-chloro-succinic acid  $\text{C}_2\text{H}_2\text{Cl}_2(\text{CO}_2\text{H})_2$ . Two acids of this constitution are formed by the union of Cl with fumaric and maleic acids respectively. They differ in melting-point and solubility (Petrieff, *Bl.* [2] 41, 309).

**Tetra-chloro-succinic acid.** *Per-chloro-ethyl ether*  $\text{C}_2\text{Cl}_4(\text{CO}_2\text{C}_2\text{Cl}_5)_2$ . [116°-120°]. From succinic ether and Cl in sunshine (Cahours, *A.* 47, 294). Small needles. Decomposed by solution in alcohol, and by alcoholic KOH, tri-chloro-acetic acid being among the products. Ammonia forms tri-chloro-acetamide and other products (*cf.* Malaguti, *A. Ch.* [3] 16, 72).

**CHLORO-SULPHO-ACETIC ACID**  
 $\text{CHCl}(\text{SO}_3\text{H})_2.\text{CO}_2\text{H}$ . From chloro-acetic acid and  $\text{ClSO}_3\text{H}$ . Formed also by oxidation of thiohydantoin by  $\text{KClO}_4$  and HCl (Andreassch, *M.* 7, 159).— $\text{BaA}''$  aq.: S. 2.5 at 17°.— $\text{K}_2\text{A}''$  1½ aq.— $(\text{NH}_4)_2\text{A}''$ : needles, v. sol. water.— $\text{Ag}_2\text{A}''$  ½ aq.: prisms.

**CHLORO-SULPHO-BENZOIC ACID**  
 $\text{C}_6\text{H}_4\text{ClSO}_3$ , i.e.  $\text{C}_6\text{H}_4\text{Cl}(\text{SO}_3\text{H})(\text{CO}_2\text{H})$  [1:3or5:2]. From o-chloro-toluene sulphonic acid by oxidation with chromic mixture (Hübner a. Majert, *B.* 6, 792).— $\text{KHA}''$  aq.— $\text{BaA}''$  2aq.— $\text{PbA}''$  2aq.

**Chloro-sulpho-benzoic acid**  
 $\text{C}_6\text{H}_4\text{Cl}(\text{SO}_3\text{H})(\text{CO}_2\text{H})$  [1:3:5]. From m-chloro-benzoic acid and  $\text{SO}_3$  (Otté, *A.* 123, 216). Needles (containing 2 aq.); v. sol. water, alcohol, and ether. With  $\text{PCl}_5$  it gives di-chloro-benzoic chloride.— $\text{KHA}''$  1½ aq.— $\text{K}_2\text{A}''$  3aq.— $\text{BaA}''$  2aq.— $\text{BaHA}''$  ½ aq.— $\text{CaHA}''$  ½ aq.— $\text{PbA}''$  3aq.

**Amide**  $\text{C}_6\text{H}_4\text{Cl}(\text{SO}_2\text{NH}_2)(\text{CONH}_2)$ : crystals.  
**Chloro-sulpho-benzoic acid**  
 $\text{C}_6\text{H}_4\text{Cl}(\text{SO}_3\text{H})(\text{CO}_2\text{H})$  [1:2:4]. From p-chloro-benzoic acid and fuming  $\text{H}_2\text{SO}_4$  at 130° (Collen, *A.* 191, 29; *B.* 9, 758, 1248). Long needles (from water). Sl. sol. alcohol and ether.

**Salts.**— $\text{NaHA}''$  2aq.— $\text{Ag}_2\text{A}''$  aq.— $\text{BaA}''$  3aq.— $\text{MgA}''$  6aq.— $\text{ZnA}''$  4aq.— $\text{CuA}''$  6aq.— $\text{PbA}''$  4aq.  
**Chloride**  $\text{C}_6\text{H}_4\text{Cl}(\text{SO}_2\text{Cl})(\text{CO}_2\text{H})$ . •[140°-150°]. Needles (from ether).

(a)-**CHLORO-TEREbic ACID**  $\text{C}_6\text{H}_4\text{ClO}$ , i.e.  $(\text{CH}_3)_2\text{C}.\text{CH}(\text{CO}_2\text{H}).\text{CH}_2.\text{CO}_2\text{H}$ ? (Frost, *A.* 226, 363). [191°]. From terebic acid (1 mol.) and  $\text{PCl}_5$  (3 mols.) (Williams, *B.* 6, 1097; Roser, *A.* 220, 265). The (8)-isomeride is formed at the same time. V. sol. hot water, alcohol, or ether. At 150° it begins to sublime.

**Reaction.**—1. Splits off HCl, forming terebic acid  $\text{C}_6\text{H}_4\text{O}$  (q. v.), when heated to 200°, or with water at 140°, or by boiling with  $\text{NaOEt}$  (W. Roser, *A.* 220, 261).—2. Boiled with water and  $\text{CaCO}_3$  it forms oxy-terebic acid.—3. With

$\text{PCl}_5$  at 130°-140° forms chloro-terebilene acid.

**Salts.**— $\text{CaA}''$  2aq.— $\text{AgHA}''$ .— $\text{PbA}''$  3aq.  
 (8)-Chloro-terebic acid  $\text{C}_6\text{H}_4\text{ClO}$ , i.e.  $(\text{CH}_3)_2\text{C}.\text{OBr}(\text{CO}_2\text{H}).\text{CH}_2.\text{CO}_2\text{H}$ ? [168°]. Formed

by the action of Cl on tereconic acid in presence of water in the cold. Colourless, transparent, trimetric crystals;  $a:b:c=0.9827:1.07157$ . Easily decomposed by boiling water into HCl and terebilic acid:  $\text{C}_6\text{H}_4\text{O}$ . (Frost, *A.* 226, 363).

**CHLORO-TEREbilene ACID**  $\text{C}_6\text{H}_4\text{ClO}$ , i.e.  $\text{Me}_2\text{C}.\text{C}(\text{CO}_2\text{H})_2.\text{CCl}.\text{CO}_2\text{H}$ ? [200°-203°]. From

chloro-terebic acid [191°] and  $\text{PCl}_5$  at 140° (W. Roser, *A.* 220, 265). Small prisms. V. sol. water. Not affected by boiling water, hardly even by boiling with moist  $\text{Ag}_2\text{O}$ .

**Salts.**— $\text{CaA}''$  2aq.— $\text{AgA}''$ .

**CHLORO-TEREPHTHALIC ACID**

$\text{C}_6\text{H}_3\text{Cl}(\text{CO}_2\text{H})_2$  [1:2:5]. [123°]. Formed by oxidising  $\text{C}_6\text{H}_3\text{Cl}(\text{C}_2\text{H}_5)_2$  with bichromate mixture and separating the two isomeric acids formed by boiling water. White crystals; insol. boiling aq; sol. ammonia, reppd. by HCl as a curdy pp. resembling  $\text{AgCl}$ ; sl. sol. warm alcohol; sol. benzene,  $\text{CHCl}_3$ ,  $\text{CS}_2$ , and ether; sol. hot ligrom. Sublimes at 100°. It distils without forming any anhydride (Istrati, *A. Ch.* [6] 6, 418).

Chloro-terephthalic acid  $\text{C}_6\text{H}_3\text{Cl}(\text{CO}_2\text{H})_2$  [2:1:4]. [above 300°]. Obtained by the action of cuprous chloride upon the diazo-compound from amido-terephthalic acid. Colourless crystals. V. sol. alcohol and ether, sl. sol. hot water.— $\text{AgA}''$ : white pp.

**Di-methyl ether**  $\text{A}''\text{Me}_2$ : [60°]; silky plates; v. sol. alcohol and ether, sl. sol. water.  
**Chloride**  $\text{C}_6\text{H}_3\text{Cl}(\text{COCl})_2$ : (c. 300°); crystalline.

**Amide**  $\text{C}_6\text{H}_3\text{Cl}(\text{CONH}_2)_2$ : [above 300°]; white crystalline crusts; sl. sol. water (Ahrens, *B.* 19, 1638).

Di-chloro-terephthalic acid  $\text{C}_6\text{H}_2\text{Cl}_2(\text{CO}_2\text{H})_2$  [5:2:4:1]. From the dihydride and dilute  $\text{HNO}_3$ . Hair-like needles; does not melt at 300°.

**Methyl ether**  $\text{MeA}''$ . [132°].

**Dihydride**  $\text{C}_6\text{H}_4\text{Cl}_2(\text{CO}_2\text{H})_2$  [c. 274°]. From succinyl-succinic ether (1 mol.) and  $\text{PCl}_5$  (4 mols.) (Levy a. Andreocci, *B.* 21, 1463). Scales (from water). V. sol. alcohol and ether, sl. sol. benzene,  $\text{CHCl}_3$ , and  $\text{CS}_2$ .— $\text{BaA}''$  3aq.— $\text{CaA}''$  4aq.— $\text{NaHA}''$  3aq.— $\text{Ag}_2\text{A}''$ .— $\text{Me}_2\text{A}''$ . [110°].— $\text{Et}_2\text{A}''$ . [71°].

**TRI-CHLORO-DI-THIENYL-ETHANE**

$\text{CCl}_3.\text{CH}(\text{C}_6\text{H}_4\text{S})_2$ . [76°]. Obtained by adding  $\text{H}_2\text{SO}_4$  to a mixture of thiophene and chloral, dissolved in acetic acid (Peter, *B.* 17, 1341). Colourless tables. V. sol. ether, petroleum-ether,  $\text{CS}_2$ , and hot alcohol, sl. sol. cold alcohol. Heated with isatin and  $\text{H}_2\text{SO}_4$  it gives a violet-red colour.

**DI-CHLORO-DI-THIENYL-ETHYLENE**

$\text{CCl}_2.\text{C}(\text{C}_6\text{H}_4\text{S})_2$ . Formed by boiling tri-chloro-di-thienyl-ethane with alcoholic KOH, or, better, KCN (Peter, *B.* 17, 1343). Colourless oil. Volatile with steam. With isatin and  $\text{H}_2\text{SO}_4$  it gives a violet-blue colour.

**CHLORO-THIENYL METHYL KETONE**

$\text{C}_6\text{SH}_4\text{Cl.OO.CH}_3$ . *Chloro-acetothienone*. [52°].

Formed by the action of acetyl chloride upon chloro-thiophene in presence of  $AlCl_3$ . Large colourless tables (from alcohol or ether). Very volatile with steam. By alkaline  $KMnO_4$  it is oxidised to chloro-thiophene-carboxylic acid [140°].

*Phenyl-hydrazide*

$C_6H_5Cl.C(N_2HPh).CH_3$ . [108°]; yellow tables; sol. hot alcohol (Gattermann a. Römer, B. 19, 693).

*Isomeride: THIENYL CHLORO-METHYL KETONE.*

CHLORO-THIO-ACETIC ACID  $CH_3Cl.CS.OH$ .

*Ethyl ether* A'Et. (187°). Prepared by heating chloro-acetic ether with  $P_2S_5$  at 140° (Meyer, B. 14, 1508). Liquid.

Di-chloro-thio-acetic acid  $CHCl_2.CS.OH$ .

*Ethyl ether* A'Et. (178°). Prepared by heating di-chloro-acetic ether with  $P_2S_5$  at 180° (Meyer, B. 14, 1507). Oil.

*p-CHLORO-DI-THIO-BENZOIC ACID*

$C_6H_4Cl.CS_2.H$ . From  $C_6H_4Cl.CCl_2$  and alcoholic potassium sulphide (Engelhardt a. Latschinoff, Z. 1868, 459).— $HgA'$ : greenish-golden laminae (from alcohol).— $PbA'$ : brick-red pp.

CHLORO-THIO-CARBONYL CHLORIDE v. THIO-CARBONYL CHLORIDE, vol. i. p. 695. See also PER-CHLORO-METHYL MERCAPTAN.

CHLORO - THIO - CARBONYL SULPHUR-CHLORIDE  $CSCl.SCl$ . (140° *in vacuo*). Oil. Formed by heating  $CSCl_2$  with sulphur at 130°–150°. By chlorine it is converted into per-chloro-methyl-mercaptan and sulphur chloride, as follows:  $2SCl.SCl + 8Cl_2 = 2CCl_2.SCl + S_2Cl_2$ . Heated with sulphur at about 160° it yields  $CS_2$  and  $S_2Cl_2$  (Klason, B. 20, 2381).

CHLORO-THIO-FORMIC ACID  $Cl.CO.S.H$ .

*Amyl ether*  $Cl.CO.S.C_5H_{11}$ . (193°). S.G. 1.078.  $\mu_D$  1.4766.

*Preparation*.—By saturating amyl mercaptan with  $COCl_2$  and, after a few days, fractionally distilling the product (H. Schöne, J. pr. [2] 32, 243).

*Properties*.—A liquid of unpleasant odour, between that of amyl alcohol and that of mercaptan. It does not fume in the air.

*Reactions*.—1. Converted by  $NaSMe$  into  $CO(SC_2H_5)(SMe)$ .—2. Converted by  $NaOEt$  into  $CO(SC_2H_5)(OEt)$ .—3. Dry  $NH_3$  forms  $CO(SC_2H_5)(NH_3)$ .—4. With *aniline* it forms  $CO(S.C_6H_5)NPhH$  (v. PHENYL THIO-CARBAMIC ACID).—5. It reacts with urea forming  $NH_2.CO.NH.CO.SC_2H_5$  (v. THIO-ALLOPHANIC ACID). 6. With phenyl - thio - urea it gives rise to  $NPhH.CS.NH.CO.S.C_2H_5$  (v. PHENYL-DI-THIO-ALLOPHANIC ACID).—7. With diphenyl-thio-urea it forms  $NPhH.CS.NPh.CO.S.C_2H_5$  (v. DI-PHENYL-DI-THIO-ALLOPHANIC ACID).

*Ethyl ether*  $Cl.CO.SEt$ . (136°). S.G. 1.164. From  $COCl_2$  and mercaptan (Salomon, J. pr. [2] 7, 252). Oil. Converted by  $NH_3$  into  $NH_2.CO.SEt$ .

Chloro-thio-formic acid  $Cl.CS.OH$ .

*Ethyl ether*  $Cl.CS.OEt$ . (180°). Formed in small quantity by the action of alcohol on  $2SCl_2$  (Klason, B. 20, 2384). Converted by  $NH_3$  into xanthogenamide  $NH_2.CS.OEt$ .

Chloro-di-thio-formic ether  $Cl.CS.SEt$ . (100°) *in vacuo*. S.G. 1.141. From  $CSCl_2$  and  $EtSH$ . Yellow oil, smelling like garlic (K.).

CHLORO-THIOPHENE  $C_4H_3ClS$ . (130°). Obtained, together with di-chloro-thiophene, by

passing chlorine into crude thiophene (Weitz, B. 17, 794). Strongly refractive colourless oil. Gives the indophenine reaction.

Di-chloro-thiophene  $C_4H_2Cl_2S$ . (170°). Obtained, together with the mono-chloro-thiophene, by passing chlorine into crude thiophene (Weitz, B. 17, 794). Heavy oil. Gives the indophenine reaction.

Tri-chloro-thiophene  $C_4HCl_3S$ . (206° uncor.). A by-product in the preparation of tetra-chloro-thiophene (Rosenberg, B. 19, 650). Heavy oil. Gives the indophenine reaction.

Tetra-chloro-thiophene  $C_4Cl_4S$ . [36°]. (245°). Obtained by passing chlorine into di-bromothiophene (Weitz, B. 17, 792). Long white needles.

CHLORO-THIOPHENE-CARBOXYLIC ACID  $C_4H_3Cl(CO_2H)$ . *Chloro-thiophenic acid*. [140°]. Formed by oxidation of chloro-thienyl methyl ketone with alkaline  $KMnO_4$ . Colourless needles (from hot water). Sublimes in spikes. Sol. hot water (Gattermann a. Römer, B. 19, 694).

TETRA - CHLORO - THIOPHENE TETRA - CHLORIDE  $C_4Cl_4S$ . [215°].

*Preparation*.—Chlorine is passed into a solution of iodo-thiophene in  $CHCl_3$ . The liquid is shaken with aqueous  $NaOH$ , the chloroform evaporated, the residue extracted with alcohol and crystallised from chloroform.

*Properties*.—Thick prisms, resembling urea. A pungent, but not unpleasant odour. V. sol. chloroform, ether, benzene,  $CS_2$ , glacial acetic acid, and alcohol (C. Willgerodt, J. pr. [2] 33, 150).

TRI - CHLORO - THIOPHENE - SULPHONIC ACID  $C_4HCl_3SO_2H$ . Formed by boiling the anhydride with water or alkalis.

*Anhydride*  $(C_4HCl_3SO_2)_2O$ . Formed by the action of pyrosulphuric acid upon tri-chloro-thiophene. White glistening crystals. Sol. benzene, nearly insol. water, alcohol, and ether (Rosenberg, B. 19, 651).

CHLORO - THYMOHYDROQUINONE v. CHLORO-HYDRO-THYMOQUINONE.

TRI - CHLORO - THYMOL  $C_{10}H_7Cl_3O$  i.e.  $C_6Cl_3(C_4H_3)(OH)$ . [61°]. From thymol and  $Cl$  in daylight (Lallemand, A. Ch. [3] 49, 148). Lemon-yellow monoclinic prisms. Decomposes at about 180°. Conc.  $H_2SO_4$  at 100° converts it into a crystalline body [45°] (250°).

Penta-chloro-thymol  $C_{10}H_2Cl_5O$ . [98°]. From thymol and  $Cl$  in bright daylight (L.). Hard crystals. At 200° it splits up into propylene,  $HCl$ , and tri-chloro-cresol.

*o*-CHLORO-THYMOQUINONE  $C_9H_6MePrClO$ , [1:4:2:3:4]. Formed by oxidation of the corresponding hydroquinone with  $FeCl_3$ . Yellowish mobile oil. Easily volatile with steam. V. sol. alcohol and ether (Schniter, B. 20, 1317).

*m*-Chloro - thymoquinone  $C_9H_6MePrClO$ , [1:4:5:3:6]. Formed from *m*-bromo-thymoquinone by treatment with chlorine, the  $Br$  being replaced by  $Cl$ . Oil (Schniter, B. 20, 1319).

Di - chloro - thymoquinone  $C_9Cl_2MePr<O$  [99°]. The ethereal extract from the product of the action of  $HCl$  on thymo-quinone-chlorimide (q. v.) is evaporated and distilled with steam. It crystallises in the receiver.

*Properties*.—Trimetric tablets (from alcohol).

turned brown by light. Not reduced by  $\text{SO}_2$ , Andersen, *J. pr.* [2] 23, 176).

**CHLORO - THYMO - QUINONE CHLORIMIDE**  $\text{C}_9\text{H}_7\text{Cl}_2\text{O}_2\text{N}$ . An oil prepared by

adding a solution of bleaching powder to the hydrochloride of chloro-amido-thymol, exactly as described under thymo-quinone-chlorimide.

**Reactions.**—Conc.  $\text{HCl}$  acts upon it exactly as it does upon thymo-quinone-chlorimide, forming chloro-amido-thymol, chloro-thymo-quinone, and di-chlorothymoquinone (*q. v.*) (Andersen, *J. pr.* 131, 187).

**CHLORO-TIGLIC ACID**  $\text{C}_9\text{H}_7\text{Cl}_2\text{O}_4$ . [69°]. 210°. Formed by the action of alcoholic  $\text{NaOH}$  upon (a) di-chloro-di-methyl-succinic acid  $\text{C}_9\text{H}_{10}\text{Cl}_2\text{O}_4$ , or by heating the silver-salt with water (Otto a. Beckurts, *B.* 18, 53). Formed also by treating methyl-acetoacetic ether with  $\text{PCl}_5$  followed by water (Rücker, *M.* 20, 54; Demarcay, *B.* 10, 1177). Glistening plates, or small needles. Sublimable and easily volatile with steam. *V. sol.* alcohol and ether, *l. sol.* cold water. Decomposed by aqueous  $\text{NaOH}$  at 160° into  $\text{CO}_2$  and methyl ethyl ketone (Friedrich, *A.* 219, 859).— $\text{BaA}^+$ ,  $\text{ZnA}^+$ ,  $\text{LiA}^+$ ,  $\text{K}^+$ .

**Ethyl ether EtA'**. (174°) (B.); (179°) (D.).

**DI-CHLORO-TOLUENEBENZOYL** *v.* DI-CHLORO-OXY-METHYL-QUINOLINE.

**o-CHLORO-TOLUENE**  $\text{C}_7\text{H}_6\text{Cl}$  *q. v.*

$\text{C}_7\text{H}_5(\text{CH}_3)\text{Cl}$  [1:2]. Mol. w. 126.5. (154° uncor.).

**Formation.**—1. In small quantity, together with the *p*-modification, by chlorinating toluene in presence of iodine (Hübner a. Majert, *B.* 6, 90).—2. By running a solution of  $\text{NaNO}_2$  into a hot solution of *o*-toluidine, and  $\text{Cu}_2\text{Cl}_2$  in dilute  $\text{HCl}$  (Sandmeyer, *B.* 17, 2651; *cf.* Beilstein a. Kuhlberg, *A.* 156, 79).—3. By heating *o*-diazotoluene with a large excess of strong  $\text{HCl}$ ; the yield is 40 p.c. of the theoretical (Gasiorowski a. Wajsa, *B.* 18, 1939).—4. By decomposing with superheated steam the sulphonic acid obtained by acting on commercial mono-chloro-toluene with sulphuric acid. The *o*-compound is much more easily sulphonated than the *p*-compound, and the  $\text{Ca}$  and  $\text{Na}$  salts of the resulting acid are much less soluble. The separation is, however, not a perfect one (Seelig, *A.* 237, 151, 155).

**Properties.**—Liquid. Converted by oxidation into *o*-chloro-benzoic acid (Wroblewsky, *Z.* [2] 4, 460). On nitration it gives a mixture of  $\text{C}_7\text{H}_4(\text{CH}_3)\text{Cl}(\text{NO}_2)$  [1:2:5] and [1:2:6] (Hönig, *B.* 20, 2417).

**m-Chloro-toluene**  $\text{C}_7\text{H}_5(\text{CH}_3)\text{Cl}$  [1:3]. (156°). Formed by displacement of  $\text{H}_2$  by  $\text{Cl}$  through the diazo-reaction. Formed also by eliminating  $\text{NH}_3$  from chloro-*p*-toluidine (Wroblewsky, *A.* 168, 199). Oxidised by  $\text{CrO}_3$  to *m*-chloro-benzoic acid.

**p-Chloro-toluene**  $\text{C}_7\text{H}_5(\text{CH}_3)\text{Cl}$  [1:4]. [6:5°]. 160°. S.V. 184-91 (R. Schiff, *A.* 220, 99). S.G. 1.080.

**Formation.**—1. By chlorinating toluene in presence of iodine,  $\text{MoCl}_5$  or other carriers (Deville, *A. Ch.* [6] 8, 178; Beilstein a. Geitner, *A.* 139, 881; *BL* [2] 1, 251; Aronheim a. Dietrich, *B.* 8, 1402).—2. By running a solution of  $\text{NaNO}_2$  into a hot solution of *p*-toluidine and  $\text{Cu}_2\text{Cl}_2$  in dilute  $\text{HCl}$  (Sandmeyer, *B.* 17, 2651; *cf.* Hübner

a. Majert, *B.* 6, 794).—3. By heating *p*-diazotoluene with a large excess of  $\text{HCl}$ ; the yield is 40 p.c. of the theoretical (Gasiorowski a. Wajsa, *B.* 18, 1939).

**Properties.**—Liquid. Not attacked by water at 200°, nor by alcoholic  $\text{NH}_3$  at 100° or alcoholic  $\text{Na}_2\text{S}$ ,  $\text{NaHS}$ , or  $\text{NaOEt}$  at 150°. Chromic mixture gives *p*-chloro-benzoic acid. On nitration it gives (4:2:1) chloro-nitro-toluene [38°], and (4:3:1) chloro-nitro-toluene [9°] (Goldschmidt a. Hönig, *B.* 19, 2438).

**o-chloro-toluene v. BENZYL CHLORIDE.**

(*B*). Di-chloro-toluene  $\text{C}_7\text{H}_4(\text{CH}_3)\text{Cl}_2$  [1:2:4]. (197°) (S.). S.G.  $\frac{20}{4}$  1.2460 (L. a. K.). From  $\text{C}_7\text{H}_5\text{MeCl}(\text{NO}_2)$  [1:2:4] *via*  $\text{C}_7\text{H}_5\text{MeCl}(\text{NH}_2)$  (Lellmann a. Klotz, *A.* 231, 314). Formed also by chlorinating *p*-chloro-toluene (Seelig, *A.* 237, 167). Oil. Gives di-chloro-benzoic acid [158°].

Di-chloro-toluene  $\text{C}_7\text{H}_4(\text{CH}_3)\text{Cl}_2$  [1:2:5]. [5°] (194° uncor.) at 745 mm. S.G.  $\frac{20}{4}$  1.2535. From  $\text{C}_7\text{H}_5\text{Me}(\text{NH}_2)\text{Cl}$  [1:2:5] by diazo-reaction (Lellmann a. Klotz, *A.* 231, 318). Gives di-chloro-benzoic acid [156°].

Di-chloro-toluene  $\text{C}_7\text{H}_4(\text{CH}_3)\text{Cl}_2$  [1:3:5]. [26°] (195° uncor.) at 729 mm. Prepared from  $\text{C}_7\text{H}_5\text{Me}(\text{NH}_2)\text{Cl}_2$  [1:4:3:5] by diazo-reaction (Lellmann a. Klotz, *A.* 231, 323). Gives di-chloro-benzoic acid [182°].

(*a*). Di-chloro-toluene  $\text{C}_7\text{H}_4(\text{CH}_3)\text{Cl}_2$  [1:2:3]. (197°). Formed by the action of chlorine on toluene in presence of ferric chloride or other carriers (Seelig, *A.* 237, 157). Yields a nitro-derivative [51°] or a dinitro-derivative [122°]. On oxidation with alkaline permanganate it gives di-chloro-benzoic acid [166°].

Di-chloro-toluene  $\text{C}_7\text{H}_4(\text{CH}_3)\text{Cl}_2$  [1:3:4]. (200° uncor.) at 740 mm. S.G.  $\frac{20}{4}$  1.2512.

**Formation.**—1. From  $\text{C}_7\text{H}_5\text{MeCl}(\text{NH}_2)$  [1:3:4] by diazo-reaction (Lellmann a. Klotz, *A.* 231, 311). 2. A product of the chlorination of toluene in presence of carriers (Beilstein a. Geitner, *A.* 139, 341; Beilstein a. Kuhlberg, *A.* 150, 813; Aronheim a. Dietrich, *B.* 8, 1401; Neuhof, *Z.* [2] 2, 653; Schultz, *A.* 187, 263).—3. From chloro-*p*-cresol and  $\text{PCl}_5$  (Schall a. Dralle, *B.* 17, 2535).

**Properties.**—Oil. Gives on oxidation di-chloro-benzoic acid [201°].

**o-p-Di-chloro-toluene** [4:1]  $\text{C}_7\text{H}_3\text{Cl}_2(\text{CH}_3)_2$ . *p-Chloro-benzyl chloride*. [29°]. (213°).

**Formation.**—1. By chlorinating *p*-chloro-toluene at 160° (Neuhof, *A.* 146, 320; Jackson a. Field, *Am.* 2, 85; *P. Am.* A. 14, 54; *B.* 11, 904). 2. By chlorinating cold benzyl chloride in presence of iodine (N.).

**Properties.**—Needles or prisms; insol. water, sol. alcohol and ether. Powerfully attacks the mucous membrane. Very volatile. Oxidation gives *p*-chloro-benzoic acid. Boiling water forms *p*-chloro-benzylalcohol. Boiling aqueous  $\text{Pb}(\text{NO}_3)_2$  gives *p*-chloro-benzoic aldehyde. Alcoholic  $\text{KOCy}$  forms phenylacetone.

**o-Di-chloro-toluene v. BENZYLIDENE CHLORIDE.**

(*a*). Tri-chloro-toluene  $\text{C}_7\text{H}_3(\text{CH}_3)\text{Cl}_3$  [1:2:4:5]. [82°]. (230°). Is formed, together with the (*B*)-derivative, by passing chlorine into toluene in presence of  $\text{FeCl}_3$  or other carriers (Limpricht, *A.* 139, 803; Aronheim a. Dietrich, *B.* 8, 1401; Schultz, *A.* 187, 274; Seelig, *A.* 237, 138). Long needles, sol. alcohol. Forms a sulphonic acid, which is decomposed by superheated steam at

160°. Chromic mixture oxidises it to tri-chloro-benzoic acid [168°] (Janausch, A. 142, 801).

(B)-Tri-chloro-toluene  $C_6H_3(CH_3)Cl_3$  [1:2:3:4]. [41°]. (232°). Is formed together with the (a) isomeride by passing chlorine into toluene in presence of  $FeCl_3$  (Seelig, A. 237, 183). Forms a sulphonate, which is decomposed by superheated steam at about 210°. Gives tri-chloro-benzoic acid [129°].

*o*-*ortho*-Tri-chloro-toluene  $C_6H_3Cl_3CH_2Cl$ . (240°). S.G. 1.44. A product of the chlorination of toluene and of benzyl chloride (Naquet, A. Suppl. 2, 248; Kekulé, K. 2, 561). Formed also by chlorinating boiling di-chloro-toluene (Beilstein a. Kuhlberg, A. 146, 817). Liquid. Alcoholic KOAc gives  $C_6H_3Cl_3CH_2OAc$ .

*o*-*ortho*-Tri-chloro-toluene [2:1]  $C_6H_3Cl_3CHCl_2$ . *o*-Chloro-benzylidene chloride. (c. 230°). From salicylic aldehyde and  $PCl_5$  (Henry, B. 2, 135; Z. [2] 5, 871). Formed also, together with the following, by chlorinating benzylidene chloride in presence of iodine (B. a. K.). Water at 170° converts it into chloro-benzoic aldehyde. Chromic mixture forms *o*-chloro-benzoic acid. Distillation with dry oxalic acid forms *o*-chloro-benzoic aldehyde (Anschütz, A. 226, 19).

*o*-*ortho*-Tri-chloro-toluene [4:1]  $C_6H_3Cl_3CHCl_2$ . *p*-Chloro-benzylidene chloride. (234°). Formed as above (B. a. K.). Resembles the preceding in its reactions.

*o*-*ortho*-Tri-chloro-toluene v. BENZOTRICHLORIDE. Tetra-chloro-toluene  $C_6HCl_4CH_3$ . [96°] (L.); [91°] (B. a. K.). (276° cor.). Among the products of chlorinating toluene in presence of  $SbCl_5$  (Limpricht, A. 189, 327). Slender needles (from alcohol).

Tetra-chloro-toluene  $C_6H_2Cl_4$ . (280°-290°). From di-chloro-toluene tetrachloride and alcoholic KOH (Pieper, A. 142, 305).

Tetra-chloro-toluene  $C_6H_2Cl_4CH_2Cl$ . Tri-chloro-benzyl chloride. (273°). S.G. 1.547. From  $C_6H_2Cl_4CH_3$  and Cl at high temperatures (Beilstein a. Kuhlberg, A. 160, 286).

Tetra-chloro-toluene  $C_6H_2Cl_4CHCl_2$  [4:3:1]. (a)-Di-chloro-benzylidene chloride. (257°). S.G. 1.618. From Cl and boiling (4,3,1)-di-chloro-toluene (B. a. K.). Water at 220° gives di-chloro-benzoic aldehyde.

Tetra-chloro-toluene  $C_6H_2Cl_4CHCl_2$  [1:3:6]. (B)-Di-chloro-benzylidene chloride. (c. 260°). Formed by passing chlorine into (B)-di-chloro-toluene heated at 230° (Seelig, A. 237, 167). Is converted into dichlorobenzoic aldehyde on treating with conc.  $H_2SO_4$ .

Tetra-chloro-toluene [2:1]  $C_6H_2Cl_4CCl_3$ . *o*-Chloro-benzotrichloride. [30°]. (260°). From *o*-oxy-benzoic acid by distilling with  $PCl_5$  (Kolbe a. Leutemann, A. 115, 195). Water at 150° gives *o*-chloro-benzoic acid.

Tetra-chloro-toluene [3:1]  $C_6H_2Cl_4CCl_2$ . *m*-Chloro-benzotrichloride. (335°). From *m*-sulpho-benzoic acid and  $PCl_5$  (Carius a. Kämmerer, A. 181, 158).

Tetra-chloro-toluene [4:1]  $C_6H_2Cl_4CCl_3$ . *p*-Chloro-benzotrichloride. (245°).

Formation.—1. From benzotrichloride and Cl in presence of carriers (Beilstein a. Kuhlberg, A. 146, 817).—2. From benzoyl chloride and  $PCl_5$  (Limpricht, A. 184, 57).—3. From *p*-oxy-benzide

$C_6H_4 \begin{array}{c} O \\ \diagup \quad \diagdown \\ \text{CO} \end{array}$  and  $PCl_5$ . The product is freed from

$POCl_3$  by distillation, and the residue shaken with dilute NaOH (Klepl, J. pr. [2] 28, 204).

Properties.—Oil. Converted by warm conc.  $H_2SO_4$  or by water at 200° into *p*-chloro-benzoic acid.

Penta-chloro-toluene  $C_6Cl_5CH_3$ . [218°]. (301°). Formed by chlorinating toluene in presence of iodine (B. a. K.). Needles (from benzene).

Penta-chloro-toluene  $C_6HCl_4CH_2Cl$ . Tetra-chloro-benzyl chloride (296°). S.G. 1.634. From boiling tetra-chloro-toluene and Cl (B. a. K.). Further chlorination gives  $C_6Cl_5$  and  $CCl_4$  (Beilstein a. Kuhlberg, Z. [2] 5, 527).

Penta-chloro-toluene  $C_6HCl_4CHCl_2$  [2:4:5:1]. (a)-Tri-chloro-benzylidene chloride. (281°). S.G. 1.607. From Cl and boiling tri-chloro-toluene (B. a. K.). Needles (below 0°). Water at 250° or cold fuming  $H_2SO_4$  gives tri-chloro-benzoic aldehyde.

Penta-chloro-toluene  $C_6HCl_4CHCl_2$  [4:3:2:1]. (B)-Tri-chloro-benzylidene chloride. (84°). (c. 280°). Formed by passing phosgene through boiling (B)-tri-chloro-toluene (Seelig, A. 237, 146). Oil solidifying to a crystalline mass. Sol. petroleum ether. Treated with fuming sulphuric acid it forms (B)-tri-chloro-benzoic aldehyde.

Penta-chloro-toluene  $C_6HCl_4CCl_3$ . Di-chloro-benzotrichloride. (273°). S.G. 1.587. From crude di-chloro-toluene and Cl (B. a. K.). Water at 200° gives a mixture of di-chloro-benzoic acids.

Hexa-chloro-toluene  $C_6HCl_5$ , i.e.  $C_6Cl_5CH_2Cl$ . Penta-chloro-benzyl chloride. [103°]. (326°). From benzyl chloride and Cl in presence of  $SbCl_5$ . Formed also by chlorinating boiling penta-chloro-toluene (B. a. K.; cf. Deville, A. 44, 304). Slender needles; sl. sol. alcohol; v. sol. benzene. Alcoholic KOAc at 200° gives  $C_6Cl_5CH_2OH$ .

Hexa-chloro-toluene  $C_6HCl_5CHCl_2$ . Tetra-chloro-benzylidene chloride. (306°). S.G. 1.704. From Cl and boiling tetra-chloro-toluene  $C_6HCl_4CH_3$  (B. a. K.). Water at 280° gives tetra-chloro-benzoic aldehyde.

Hexa-chloro-toluene  $C_6HCl_5CCl_3$ . Tri-chloro-benzotrichloride. [82°]. (308°). From Cl and boiling  $C_6HCl_5CH_2$  (Beilstein a. Kuhlberg, A. 160, 305). Slender needles (from alcohol). Water at 260° gives tri-chloro-benzoic acid.

Hepta-chloro-toluene  $C_6Cl_7$ . Penta-chloro-benzylidene chloride. [110°]. (334°). Formed by chlorinating benzylidene chloride with the aid of carriers (B. a. K.). Flat laminae (from alcohol). Sl. sol. cold alcohol, v. sol. boiling alcohol. Water at 300° does not act upon it.

Hepta-chloro-toluene  $C_6HCl_6CCl_3$ . [104°]. (316°). From Cl and boiling  $C_6HCl_6CH_3$  (B. a. K.). Short needles (from alcohol); m. sol. hot alcohol. Water at 270° gives tetra-chloro-benzoic acid.

CHLORO-TOLUENE-AZOKY-CHLORO-TOLUENE v. AZOKY-COMPOUNDS.

DI-CHLORO-TOLUENE TETRACHLORIDE  $C_6H_2Cl_4$ , i.e.  $C_6H_2Cl_4CH_3$ . [150°]. From toluene and Cl (Pieper, A. 142, 304). Prisms (from  $CS_2$ ). Alcoholic NaOH at 510° gives di-chloro-benzoic acid [208°] and tetra-chloro-toluene (c. 285°).

*p*-CHLORO-TOLUENE-(B)-SULPHONIC ACID  $C_6H_4MeCl(SO_3H)$  [1:4:2]. From *p*-chloro-toluene and  $H_2SO_4$  (Vogt a. Henninger, A. 185, 869). Also from the corresponding *p*-toluidine *o*-sul-

phonic acid by displacement of  $\text{NH}_2$  by  $\text{Cl}$  (Jenssen, *A.* 172, 289).

**Salts.**— $\text{BaA}'_2$  1:1 aq. S. 1.9 at  $16^\circ$ .— $\text{BaA}'_2$  aq. (Hübner a. Majert, *B.* 6, 790).— $\text{KA}'$  aq.— $\text{CaA}'_2$  6aq.— $\text{PbA}'_2$  8aq.— $\text{CuA}'_2$  7aq.

**Amide**  $\text{C}_6\text{H}_4(\text{NH}_2)\text{Me}.\text{SO}.\text{NH}_2$  [138°]. From  $\text{C}_6\text{H}_4(\text{NH}_2)\text{Me}.\text{SO}.\text{NH}_2$  by  $\text{HCl}$  and nitrous acid gas (Heffter, *A.* 221, 209).

**p-Chloro-toluene (a)-sulphonic acid**  $\text{C}_6\text{H}_4\text{MeCl}(\text{SO}_3\text{H})$  [1:4:3]. Formed, together with the preceding, by sulphonating *p*-chloro-toluene (Vogta. Henninger, *A.Ch.* [4] 27, 129). Converted by potash-fusion into orcin.

**Salts.**— $\text{KA}'$  1:1 aq. laminae.— $\text{NaA}'$  5aq.— $\text{BaA}'_2$  2aq. S. 5.71 at  $16.5^\circ$  (V. a. H.).— $\text{BaA}'_2$  1:1 aq. S. 14 at  $14^\circ$  (Hübner a. Majert, *B.* 6, 790).— $\text{BaA}'_2$  aq (V. a. H.).— $\text{BaA}'_2$  7aq (Engelbrecht, *B.* 7, 796).— $\text{CdA}'_2$  2aq.— $\text{PbA}'_2$  6aq.— $\text{CuA}'_2$  10aq.

**o-Chloro-toluene sulphonic acid**  $\text{C}_6\text{H}_4\text{MeCl}(\text{SO}_3\text{H})$  [1:2:3or5]. From *o*-chloro-toluene and  $\text{H}_2\text{SO}_4$  (Hübner a. Majert, *B.* 6, 790). Sodium amalgam gives toluene *m*-sulphonic acid. Oxidation forms chloro-sulpho-benzoic acid.— $\text{NH}_4\text{A}'$  aq.— $\text{KA}'$  1:1 aq.— $\text{NaA}'$  3aq.— $\text{BaA}'_2$  2aq.— $\text{CaA}'_2$  2aq.— $\text{PbA}'_2$  2aq.— $\text{CuA}'_2$  1:1 aq.

**Chloro-toluene sulphonic acid**  $\text{C}_6\text{H}_4\text{MeCl}(\text{SO}_3\text{H})$  [1:2:4]. From the amide and  $\text{HCl}$  at  $150^\circ$ . **Salts.**— $\text{BaA}'_2$ — $\text{KA}'$ .

**Chloride**  $\text{C}_6\text{H}_4\text{ClMe}.\text{SO}_2.\text{Cl}$ . Oil. **Amide**  $\text{C}_6\text{H}_4\text{Me}(\text{SO}_2.\text{NH}_2).\text{NH}.\text{C}_6\text{H}_4\text{Me}.\text{SO}_2.\text{NH}_2$  and  $\text{HCl}$  (Paysan, *A.* 221, 212).

**p-Chloro-toluene  $\omega$ -sulphonic acid**  $[\text{4:1}]\text{C}_6\text{H}_3\text{Cl}_2\text{CH}_2.\text{SO}_3\text{H}$ . **Chlorobenzyl sulphonic acid**  $[\text{108}^\circ]$  (?). From  $\text{C}_6\text{H}_5\text{Cl}.\text{CH}_2.\text{Cl}$  and aqueous  $\text{K}_2\text{SO}_4$  (Böhler, *A.* 154, 56; Vogt a. Henninger, *A.Ch.* [4] 27, 129; Jackson a. White, *Am.* 2, 159; *P. Am.* *A.* 14, 312; *B.* 13, 1217). Potash-fusion gives *p*-oxy-benzoic acid.

**Salts.**— $\text{KA}'$  (B.; J. a. W.)— $\text{KA}'$  aq. (V. a. H.): sol. boiling alcohol.— $\text{NaA}'$ : flat crystals (from water) or pearly scales (from alcohol).— $\text{BaA}'_2$  aq.— $\text{BaA}'_2$  2aq (J. a. W.): Needles.— $\text{CaA}'_2$  2aq.— $\text{CaA}'_2$  7aq (J. a. W.): trimetric crystals.— $\text{CuA}'_2$  2aq: pale green needles.— $\text{PbA}'_2$  aq (J. a. W.): long needles.— $\text{ATbOH}$  aq.— $\text{A}_2\text{PbO}_2$ : Needles.

**Chloride**  $\text{C}_6\text{H}_4\text{ClCH}_2.\text{SO}_2.\text{Cl}$  [ $85.5^\circ$ ]: flat crystals, v. sol. ether.

**CHLORO-o-TOLUIDIC ACID**  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}(\text{CO}_2\text{H})$  [2:4:1]. [ $130^\circ$ ]. Formed, together with the [6:3:1] isomeride [ $166^\circ$ ], by oxidation of chloro-*o*-xylene  $\text{C}_6\text{H}_3(\text{CH}_3)_2\text{Cl}$  [1:2:4] with  $\text{HNO}_3$  (Krüger, *B.* 18, 1757). Fine needles or thick prisms. By further oxidation by means of  $\text{KMnO}_4$ , both acids yield chloro-phthalic acid [ $130^\circ$ – $134^\circ$ ]. By  $\text{KOH}$  fusion it is converted into oxy-*o*-toluic acid  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{OH})(\text{CO}_2\text{H})$  [2:4:1].— $\text{CaA}'_2$  3aq.

**Chloro-*p*-toluic acid**  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}(\text{CO}_2\text{H})$  [4:2:1]. [ $150^\circ$ ]. Formed by the action of boiling dilute  $\text{HNO}_3$  on chloro-cymene (derived from thymol and  $\text{PCl}_5$ ). Slightly volatile with steam. (Fleiti a. Cross, *G.* 18, 290).

**Chloro-*o*-toluic acid**  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}(\text{CO}_2\text{H})$  [2:3:1]. [ $164^\circ$ ]. Formed by oxidation of chloro-*o*-xylene  $\text{C}_6\text{H}_3(\text{CH}_3)_2\text{Cl}$  [1:2:3] by  $\text{HNO}_3$  (Krüger, *B.* 18, 1758). Needles. V. sol. alcohol. By further oxidation by means of  $\text{KMnO}_4$ , it yields chloro-phthalic acid [ $181^\circ$ ].— $\text{A}'_2\text{Ca}$  2aq: sparingly soluble long prisms.

**Chloro-*o*-toluic acid**  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}(\text{CO}_2\text{H})$  [6:3:1]. [ $166^\circ$ ]. Formed, together with the isomeride [2:4:1], by oxidation of chloro-*o*-xylene  $\text{C}_6\text{H}_3(\text{CH}_3)_2\text{Cl}$  [1:2:4] with  $\text{HNO}_3$  (Krüger, *B.* 18, 1757). Needles. Sol. alcohol, v. sl. sol. water. By further oxidation by means of  $\text{KMnO}_4$ , both acids yield chloro-phthalic acid [ $130^\circ$ – $134^\circ$ ]. By  $\text{KOH}$  fusion it yields oxy-*o*-toluic acid [ $173^\circ$ ].— $\text{A}'_2\text{Ca}$  2aq: sparingly soluble short prisms.

**Chloro-*p*-toluic acid**  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}(\text{CO}_2\text{H})$  [4:3:1]. [ $196^\circ$ ]. Formed by the action of boiling dilute  $\text{HNO}_3$  on the chloro-cymene that is obtained from carvacrol and  $\text{PCl}_5$  (Fleischer a. Kekulé, *B.* 6, 1090; v. Gerichten, *B.* 10, 1249; 11, 366). Laminae.— $\text{CaA}'_2$  3aq.— $\text{BaA}'_2$  4aq.

**Chloro-*m*-toluic acid**  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}(\text{CO}_2\text{H})$  [3:4:1]. [ $203^\circ$ ] (V.); [ $210^\circ$  cor.] (J.); [ $204^\circ$  cor.] (H. a. K.).

**Formation.**—1. By oxidation of chloro-*m*-xylene  $\text{C}_6\text{H}_3(\text{CH}_3)_2\text{Cl}$  [1:3:4] with  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  (Vollrath, *Bl.* [2] 7, 342; Jacobsen, *B.* 18, 1761).—2. From  $\text{C}_6\text{H}_3(\text{CH}_3)(\text{NO}_2)(\text{CO}_2\text{H})$  [3:4:1] by displacement of  $\text{NO}_2$  by  $\text{Cl}$  (Bellstein a. Kreusler, *A.* 144, 182; Remsen a. Kuhara, *Am.* 3, 431).

**Properties.**—Needles (from alcohol). By  $\text{KOH}$  fusion it gives oxy-*m*-toluic acid [ $178^\circ$ ].

**Salts.**— $\text{BaA}'_2$  3aq: slender needles (V.).— $\text{CaA}'_2$  3aq.

**Ethyl ether**  $\text{EtA}'$ . ( $263^\circ$ ).

**$\omega$ -Chloro-*o*-toluic acid** **Amide** [2:1]  $\text{CH}_2\text{Cl}.\text{C}_6\text{H}_3\text{CONH}_2$  [ $\alpha$ .  $180^\circ$ ]. From the nitrile and  $\text{H}_2\text{SO}_4$  at  $90^\circ$ , followed by water (Gabriel, *B.* 20, 2234). Slender needles (from alcohol). Boiling water converts it into phthalide. At  $160^\circ$  it changes to oily 'pseudophthalimidine'  $\text{C}_6\text{H}_4\text{NO}$ .

**Nitrile**  $\text{CH}_2\text{Cl}.\text{C}_6\text{H}_3\text{CN}$ . ***o*-Cyano-benzyl chloride**. [ $61^\circ$ ]. ( $252^\circ$ ). Formed by passing  $\text{Cl}$  into the boiling nitrile of *o*-toluic acid (Gabriel a. Otto, *B.* 20, 2223). Monoclinic crystals;  $a:b:c = 778:1:294$ ;  $\beta = 80^\circ 2'$ . Sol. hot water.

**Di-chloro-toluic acid**  $\text{C}_6\text{H}_2(\text{CH}_3)_2\text{Cl}_2(\text{CO}_2\text{H})$  [ $161^\circ$ ]. From crude di-chloro-xylene ( $222^\circ$ ) and chromic mixture (Holleman, *A.* 144, 269).— $\text{CaA}'_2$  9aq.— $\text{AgA}'$ .

**Di- $\omega$ -chloro-toluic acid. Nitrile**  $\text{CHCl}_2.\text{C}_6\text{H}_3\text{CN}$ . **Cyano-benzylidene chloride**. ( $260^\circ$ ). Formed by the action of chlorine on the boiling nitrile of *o*-toluic acid (Gabriel a. Weise, *B.* 20, 3197). Fuming  $\text{HCl}$  at  $170^\circ$  gives  $\text{C}_6\text{H}_3(\text{CHO})(\text{CO}_2\text{H})$ . [ $97^\circ$ ].

**Tri- $\omega$ -chloro-*o*-toluic acid. Nitrile**  $\text{CCl}_3.\text{C}_6\text{H}_3\text{CN}$ . **Cyano-benzyl trichloride**. [ $95^\circ$ ]. ( $\alpha$ .  $280^\circ$ ). From boiling *q*-toluic nitrile and  $\text{Cl}$  (G. a. W.). Monoclinic crystals (from alcohol);  $a:b:c = 1:546:1:1:106$ ;  $\beta = 73^\circ 58'$ .

**o-CHLORO-o-TOLUIDINE**  $\text{C}_6\text{H}_3(\text{CH}_3)\text{Cl}(\text{NH}_2)$  [1:2:3]. Formed by reduction of the corresponding nitro-compound (the nitration-product of *o*-chloro-toluene). Liquid.

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{Cl}(\text{NHAc})$ : [ $186^\circ$ ]; white needles (Hönig, *B.* 20, 2417).

***s*-Chloro-toluidine**  $\text{C}_6\text{H}_4(\text{CH}_3)\text{Cl}(\text{NH}_2)$  [1:3:5]. ( $242^\circ$ ) at 730 mm. Formed by reduction of the corresponding nitro-compound. Liquid. Volatile with steam.— $\text{B'NO}_2$ : [ $198^\circ$ ], colourless needles.

**Acetyl derivative**  $\text{C}_6\text{H}_4\text{Cl}(\text{NHAc})$ : [ $198^\circ$ ]; colourless needles (Hönig, *B.* 20, 2419).

Chloro-*p*-toluidine  $C_6H_4(CH_3)Cl(NH_2)$  [1:3:4]. [7°]. (219° uncor.). Got by boiling its acetyl derivative with HCl. Elimination of  $NH_3$  gives *m*-chloro-toluene.—B'HCl.—B'HNO<sub>3</sub>. S. 2:59 at 19°.—B'H<sub>2</sub>SO<sub>4</sub>.—B'H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>.

Acetyl derivative  $C_6H_4MeCl(NHAc)$  [1:3:4]. [115°]. Formed by chlorination of *p*-acet-toluidine. Bad yield (Lellmann a. Klotz, A. 231, 309; cf. Wroblewski, A. 168, 196).

*p*-Chloro-*o*-toluidine  $C_6H_3(CH_3)Cl(NH_2)$  [1:4:2]. [22°]. (237° at 722 mm.). Colourless liquid or white crystalline solid. Formed by reduction of (4:2:1)-chloro-nitro-toluene [38°].

Salts.—B'HCl: colourless needles.—B'H<sub>2</sub>Cl.PtCl<sub>2</sub>. 2aq: fine yellow needles.

Acetyl derivative  $C_6H_3(CH_3)Cl(NHAc)$ : [131°]; long slender colourless needles, v. sol. hot water, alcohol and ether, sl. sol. cold water (Goldschmidt a. Hönig, B. 19, 2440; cf. Engelbrecht, B. 7, 797; and Beilstein a. Kuhlberg, A. 158, 336).

Chloro-*p*-toluidine  $C_6H_4(CH_3)Cl(NH_2)$  [1:2:4]. [26°]. (238°). Formed by reduction of chloro-nitro-toluene [65°] (Lellmann, B. 17, 535). Colourless crystalline solid. V. sol. all solvents except water. By diazotisation and treatment with alcohol it yields *o*-chloro-toluene.

Salts.—B'HCl: broad colourless needles.—B'H<sub>2</sub>SO<sub>4</sub>: small colourless plates.—B'H.PtCl<sub>2</sub>.

Acetyl derivative  $C_6H_4MeCl(NHAc)$ : [105°]. From  $C_6H_4Me(NHAc).N.NC_2H_5$  and boiling HClAq (Wallach, A. 235, 254).

*p*-Chloro-*m*-toluidine  $C_6H_3(CH_3)Cl(NH_2)$  [1:4:3]. [28°] (G. a. H.); [30°] (G. a. K.). (230°). Formed by reduction of (4:3:1)-chloro-nitro-toluene [3°]. White crystalline solid. The base and its salts are extremely soluble.—B'HCl: colourless tables.

Acetyl derivative  $C_6H_3(CH_3)Cl(NHAc)$ : [97°]; long silky needles, m. sol. water (Goldschmidt a. Hönig, B. 19, 2442; cf. Engelbrecht, B. 7, 797; and Gattermann a. Kaiser, B. 18, 2599).

Chloro-*o*-toluidine  $C_6H_3(CH_3)Cl(NH_2)$  [1:5:2]. [30°]. (237° uncor.) at 730 mm. From its acetyl derivative (L. a. K.). The same compound [80°], (241°) appears to be a by-product in the reduction of *o*-nitro-toluene by tin and HCl (Beilstein a. Kuhlberg, A. 156, 81).

Salt.—B'HCl: sl. sol. water.

Acetyl derivative  $C_6H_3Me(NHAc)Cl$ . [140°]. Got by chlorination of acetylated *o*-toluidine (Lellmann a. Klotz, A. 231, 317).

*o*-Chloro-*m*-toluidine  $C_6H_3MeCl(NH_2)$  [1:2:5]. [83°]. (239° at 215 mm. Obtained by reduction of the corresponding nitro-compound [44°] (Goldschmidt a. Hönig, B. 19, 2443; 20, 199; Wroblewski, A. 168, 200; Henry a. Radziszewsky, B. 2, 308, 599). Formed also as a by-product in the reduction of *m*-nitro-toluene by zinc-dust and HCl (Kock, B. 20, 1567). Glistening colourless needles of characteristic odour.

Salts.—B'HCl: long slender needles.—B'HNO<sub>3</sub>: [164°], broad colourless needles. S. 5:01 (W.).—B'H<sub>2</sub>SO<sub>4</sub>.

Acetyl derivative  $C_6H_3MeCl(NHAc)$ : [89°]; colourless plates.

Di-chloro-*p*-toluidine  $C_6H_3(CH_3)Cl_2(NH_2)$  [1:5:4]. [60°]. Needles (from dilute alcohol). V. sol. alcohol and ether. Weak base. May be sublimed.

Acetyl derivative  $C_6H_3Me(NHAc)Cl_2$  [1:4:3:5]. [201°]. From  $C_6H_3Me(NHAc)Cl$  [1:4:3] by chlorination (Lellmann a. Klotz, A. 231, 322). White needles (from alcohol). V. sol. alcohol, insol. water, sol. ether and glacial acetic acid. May be sublimed.

(8)-Di-chloro-toluidine  $C_6H_3(CH_3)Cl_2(NH_2)$ . [1:2:1:2]. [87°]. (259°). Formed by reducing (8)-di-chloro-nitro-toluene [53°] (Seelig, A. 237, 163). Plates (from methyl alcohol).

Di-chloro-toluidine  $C_6H_3(CH_3)Cl_2(NH_2)$  [1:2:4:6]. [88°]. (259°). Obtained by reducing di-chloro-nitro-toluene [-14°] (Wroblewski, A. 168, 213). Does not combine with acids.

Tri-chloro-toluidine  $C_6H_2(CH_3)Cl_3(NH_2)$  [1:2:4:6:3] or [1:2:4:5:6]. [91°] (Schultz, A. 187, 278); [95°] (Seelig, B. 18, 423). From tri-chloro-nitro-toluene [89°], tin and HCl. Needles (from alcohol).

Acetyl derivative  $C_6H_2(CH_3)Cl_3(NHAc)$ . [191°].

Benzoyl derivative  $C_6H_2(CH_3)Cl_3(NHBz)$ . [213°].

Tri-chloro-toluidine  $C_6H_2(CH_3)Cl_3(NH_2)$  [105°]. From (8)-tri-chloro-nitro-toluene, SnCl<sub>2</sub>, and HCl (Seelig, B. 18, 423). Needles.

CHLORO-TOLUQUINOLINE *v.* CHLORO-(*B*)-METHYL-QUINOLINE.

CHLORO-TOLUQUINONE  $C_6H_3(CH_3)ClO_2$ . [1:4or3:2:5]. [90° uncor.]. Formed by oxidation of di-chloro-*o*-cresol with  $K_2Cr_2O_7$  and dilute  $H_2SO_4$ . Long yellow needles. Volatile with steam, and sublimable. V. sol. alcohol, ether, &c., sol. hot water, sl. sol. cold. Dissolves in alkalis with a dark-red colour. By SO<sub>2</sub> it is reduced to chloro-hydrotoluquinone [115°] (Claus a. Sweitzer, B. 19, 929).

Chloro-toluquinone  $C_6H_3(CH_3)ClO_2$ . [105°]. From chloro-hydro-toluquinone [175°] by distillation with aqueous  $Fe_2Cl_6$  (Schmiter, B. 20, 2282).

Di-chloro-toluquinone  $C_6H_3(CH_3)Cl_2O_2$ . [1:2:4:3:6]. [105° uncor.]. Glistening yellow plates. Volatile with steam. Formed by oxidation of di-chloro-*m*-cresol with  $K_2Cr_2O_7$  and  $H_2SO_4$ . Also from *m*-cresol, HCl, and  $KClO_3$  (Southworth, A. 168, 270). Yellow tables (from alcohol). The corresponding di-chloro-hydro-toluquinone melts at [171°] (Claus a. Schweitzer, B. 19, 931).

Di-chloro-toluquinone  $C_6H_3(CH_3)Cl_2O_2$ . [1:7:2:5]. From *o*-cresol,  $KClO_3$ , and HCl (Southworth, A. 168, 274). Not obtained pure. Reduced by SO<sub>2</sub> to di-chloro-hydrotoluquinone [121°].

Tri-chloro-toluquinone  $C_6H_2(CH_3)Cl_3O_2$ . [232°]. From *o*-cresol, HCl, and  $KClO_3$  (Graebe a. Borgmann, A. 152, 248; Southworth, A. 168, 273; Knapp a. Schultz, A. 210, 176). Formed also by treating *o*-toluidine sulphonic acid with  $KClO_3$  and HCl (Hayduck, A. 172, 209). Yellow plates; sl. sol. cold alcohol, v. sol. ether. Volatile with steam.

Tetra-chloro-toluquinone  $CH_3Cl_2C_6Cl_2O_2$ . Occurs among the products of the action of HCl and  $KClO_3$  on beech-wood creosote (Gorup-Besanez, A. 143, 159; Bräuninger, A. 186, 389). Golden scales. May be sublimed. Sl. sol. cold alcohol.

**CHLORO-TOLUQUINOXALINE Dihydrate.**

Formed by heating oxy-di-hydro-toluquinoxaline with  $\text{PCl}_5$ . Long colourless needles. Insol. water, v. e. sol. other solvents. Volatile with steam (Leuckart & Hermann, B. 20, 29).

Di-chloro-toluquinoxaline  $\text{C}_6\text{H}_4\text{N}_2\text{Cl}_2$  i.e.

From di-oxy-toluquinoxaline (1 mol.) and  $\text{PCl}_5$  2 mols., at  $170^\circ$  (Hinsberg, A. 237, 350). Needles (from chloroform and petroleum-ether). Insol. water.

**DI-CHLORO-TOLUYL-BENZOIC ACID**

$\text{CH}_3\text{C}_6\text{H}_4\text{CO}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . Di-chloro-phenyl tolyl ketone carboxylic acid. From (8)-dichlorophthalic anhydride, toluene, and  $\text{AlCl}_3$  (Lo Røyer, A. 238, 357).

**CHLORO-(a)-TOLUYLIC ACID** v. **CHLORO-PHENYL-ACETIC ACID**.

**DI-CHLORO-DITOLYL**

3:4:1  $\text{C}_6\text{H}_4\text{MeCl}_2\text{C}_6\text{H}_4\text{MeCl}_2$  [1:3:4].  $[51^\circ]$ . From di-amido-ditolyl by Sandmeyer's reaction (Stolle, B. 21, 1096). Laminae (from alcohol).  $\text{CrO}_3$  gives chloro-toluic acid  $[205^\circ]$ .

**CHLORO-DI-TOLYL-tert-BUTYL ALCOHOL**  $\text{CCl}(\text{C}_6\text{H}_4\text{Me})_2\text{CMe}_2\text{OH}$ . (c.  $265^\circ$ ). From acetone-chloroform, toluene, and  $\text{AlCl}_3$  (Willgerodt & Genieser, J. pr. [2] 37, 369).

Di-chloro-tolyl-tert-butyl alcohol  $\text{CCl}_2(\text{C}_6\text{H}_4\text{Me})_2\text{CMe}_2\text{OH}$ . (c.  $245^\circ$ ). From acetone-chloroform, toluene, and  $\text{AlCl}_3$  (W. a. G.).

**CHLORO-TOLYLENE-m-DIAMINE**

$\text{C}_6\text{H}_3(\text{CH}_2\text{Cl})(\text{NH}_2)_2$  [1:4:3:5].  $[111^\circ]$ . Formed by reduction of chloro-di-nitro-toluene  $[48^\circ]$ . Gives the chrysoidine and Bismarck-brown reactions (Hönig, B. 20, 2420).

(8)-Di-chloro-tolylene-diamine  $\text{C}_6\text{H}_3(\text{CH}_2\text{Cl})_2(\text{NH}_2)_2$  [1:2:4:5:6].  $[110^\circ]$ . Formed by reducing (8)-di-chloro-di-nitro-toluene  $[102^\circ]$  (Seelig, A. 237, 164). Plates (from ligroin). On boiling with  $\text{HOAc}$  for twenty-five hours the anhydro-base is formed  $[170^\circ]$ ; brownish needles (from alcohol).

(a)-Tri-chloro-tolylene-diamine

$\text{C}_6(\text{CH}_2\text{Cl})_3(\text{NH}_2)_2$ .  $[196^\circ]$ . Formed by reduction of tri-chloro-di-nitro-toluene  $[227^\circ]$  (Seelig, B. 18, 422; A. 237, 143). White needles (from alcohol).  $\text{CrO}_3$  oxidises it to a quinone.

Acetyl derivative  $\text{C}_6(\text{CH}_2\text{Cl})_3(\text{NAc})_2$ .  $[220^\circ]$ .

(8)-Tri-chloro-tolylene-diamine

$\text{C}_6(\text{CH}_2\text{Cl})_3(\text{NH}_2)_2$ .  $[207^\circ]$ . Formed by reducing tri-chloro-di-nitro-toluene  $[141^\circ]$  with stannous chloride in alcoholic solution (Seelig, A. 237, 143). Needles (from petroleum ether). On boiling with  $\text{HOAc}$  an anhydro-base is formed, hence the substance is an orthodiamine.

**o-CHLORO-DI-TOLYL-ETHANE**

$\text{CH}_2\text{ClCH}(\text{C}_6\text{H}_4\text{CH}_3)_2$ . From  $\text{CH}_2\text{ClCHClOEt}$  (di-chloro-ether), toluene, and  $\text{H}_2\text{SO}_4$  (Hepp, B. 7, 1413). Alcoholic  $\text{KOH}$  gives  $\text{CH}_2\text{C}(\text{C}_6\text{H}_4\text{Me})_2$ .

Tri-o-chloro-di-tolyl-ethane

$\text{CCl}_2\text{CH}(\text{C}_6\text{H}_4\text{CH}_3)_2$ .  $[89^\circ]$ . S. (ether) 50; (alcohol) 2-5. From chloral, toluene, and  $\text{H}_2\text{SO}_4$  (O. Fischer, B. 7, 1191).

**DI-CHLORO-DI-TOLYL-ETHYLENE**

$\text{CCl}_2\text{C}(\text{C}_6\text{H}_4\text{CH}_3)_2$ .  $[92^\circ]$ . S. (ether) 50; (alco-

hol) 2-9. From the preceding body and alcoholic  $\text{KOH}$  (O. Fischer, B. 7, 1191). Needles.

**DI-CHLORO-DI-TOLYL-METHANE**

$\text{CH}_2(\text{C}_6\text{H}_4\text{CH}_2\text{Cl})_2$ .  $[108^\circ]$ . From benzyl chloride, methylal  $\text{CH}_2(\text{OMe})_2$ , and  $\text{H}_2\text{SO}_4$ . Laminae (Weiler, B. 7, 1181).

**o-CHLORO-m-TOLYL-PHENYL-THIO-UREA**

$\text{C}_6\text{H}_4\text{NHCS.NH.C}_6\text{H}_4\text{MeCl}$  [5:1:2].  $[109^\circ]$ . White granules. From  $\text{C}_6\text{H}_4\text{MeCl}(\text{NH}_2)$  [1:2:5] and phenyl-thiocarbimide (Goldschmidt & Hönig, B. 20, 201).

**CHLORO-TROPIC ACID**  $\text{C}_8\text{H}_7\text{ClO}_2$  i.e.

$\text{C}_6\text{H}_4\text{CCl}(\text{CO}_2\text{H})\text{CH}_2\text{OH}$ .  $[128^\circ\text{--}130^\circ]$ . From atropic acid and  $\text{HClO}$  (Ladenburg & Rügheimer, A. 217, 109). V. e. sol. water, sl. sol. benzene. Reduced by zinc-dust, iron filings, and  $\text{KOH}$  to tropic acid.

**CHLOROUS**. Adjective sometimes used as synonymous with *negative* or *acidic*; generally applied to radicles which combine with *basyllous* radicles to form salts, e.g. the radicles  $\text{SO}_3$ ,  $\text{N}_2\text{O}_5$ ,  $\text{ClO}$ , are called *chlorous*, as distinguished from  $\text{K}_2\text{O}$ ,  $\text{CaO}$ , &c., which are *basyllous*. The term *chlorous* is also sometimes applied to the more negative elements, especially to those which, like chlorine, do not displace the H of acids to form salts. The correlative term is *basyllous*.

M. M. P. M.

**CHLOROUS ACID**  $\text{HClO}_2$ ; v. **CHLORINE**, **oxy-acids** of, p. 17.

**o-CHLORO-ISOVALERIC ACID**  $\text{C}_5\text{H}_7\text{ClO}_2$  i.e.  $(\text{CH}_3)_2\text{CH.CHCl.CO}_2\text{H}$ . From sodium isovalerate and aqueous  $\text{HOCl}$  (Schlebusch, A. 141, 322). Oil; decomposed by heat.

Tri- and tetra-chloro-isovaleric acids were obtained by Dumas & Stas by chlorinating isovaleric acid in the dark. They decompose between  $110^\circ$  and  $150^\circ$ , giving off  $\text{HCl}$ .

**CHLORO-ISOVALERIC ALDEHYDE**  $\text{C}_5\text{H}_7\text{ClO}$ .  $[135^\circ]$ . S.G. 1.1-1.08. From isovaleric aldehyde and  $\text{Cl}$  at  $-18^\circ$  (Schröder, B. 4, 402). Combines with  $\text{NaHSO}_3$ .

Di-chloro-isovaleric aldehyde  $\text{C}_5\text{H}_6\text{Cl}_2\text{O}$   $[147^\circ]$ . From isovaleric aldehyde and  $\text{Cl}$  at  $15^\circ$ . Combines with  $\text{NaHSO}_3$  (Kundig, A. 114, 1).

**TRI-CHLORO-VALEROLACTIC ACID** v. **TRI-CHLORO-OXY-VALERIC ACID**.

**CHLORO-VALERO-LACTONE** v. **CHLORO-OXY-VALERIC ACID**, *Anhydride of*.

**DI-CHLORO-VALEXYLENE**  $\text{C}_2\text{H}_2\text{Cl}_2$  i.e.  $\text{CH}_2\text{ClCHCl.CH}_2\text{Cl}$ . Di-chloro-di-vinyl-methane.  $[145^\circ]$ . Formed by the action of  $\text{PCl}_5$  upon acetyl-acetone. Liquid; boils without decomposition. Readily takes up  $\text{Br}$ , forming  $\text{C}_2\text{H}_2\text{Cl}_2\text{Br}_2$ . Heated with alcoholic  $\text{KOH}$  it gives  $\text{CH}_2\text{C}(\text{OH})_2\text{C}(\text{OC}_2\text{H}_5)_2$  (Combes, A. Ch. [6] 12, 222).

**DI-CHLORO-o-VINYL-BENZOIC ACID**

$\text{C}_6\text{HCl}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$   $[121^\circ]$ . From tri-chloro-oxy-indonaphthene  $\text{C}_{10}\text{H}_7\text{Cl}_3$   $\begin{array}{c} \text{CO} \\ | \\ \text{CHCl} \end{array}$   $\text{COCl}_2$  by solution in aqueous alkalis (Zincke, B. 20, 2890). Slender needles (from dilute alcohol). Sodium amalgam converts it into o-ethyl-benzoic acid  $[68^\circ]$ .

Methyl ether MeA.  $[47^\circ]$ .

o-Etho-tri-chloro-vinyl-benzoic acid

$\text{C}_6\text{H}_3(\text{OClCO})_2\text{CO}_2\text{H}$  [1:3].  $[161^\circ]$ .

Formation.—1. By the action of  $\text{NaOHAq}$  on tetra-chloro-oxy-indonaphthene

2. Tetrachloro-(8)-naphtho-quinone is dissolved in NaOH aq. HOAc added, and the mixture oxidised with chromic acid (Zincke, B. 21, 499).

**Properties.**—Needles or plates. V. sol. alcohol and HOAc. Sodium amalgam yields o-ethyl benzoic acid.

**Methyl ether A.Me.** [75°].

**CHLORO-VINYL ETHYL OXIDE**  $C_4H_5ClO$  i.e.  $CH_2=CCl.OEt$ . (123°). S.G.  $\frac{22}{4}$  1.02 (Geuther);  $\frac{12}{4}$  1.038 (Godefroy). V.D. 3.52. From tri-chloro-ethane  $CH_3.CCl_3$  and NaOEt at 120° (Geuther, Z. 1871, 128). Formed also by the action of zinc-dust or the zinc-copper couple on the compound  $C_4H_5Cl_2O$  obtained by passing chlorine through a mixture of alcohol and  $K_2Cr_2O_7$  (Godefroy, C. R. 102, 889).

**Reactions.**—1. Br forms  $CH_2Br.CClBr.OEt$  (170°–180°), whence Cl forms  $CH_2Cl.CCl.OEt$ .—2. HCl forms  $CH_2Cl.CHCl.OEt$ .—3.  $HNO_3$  gives acetic and chloro-acetic acids.—4. Reduces ammoniacal  $AgNO_3$ , forming a mirror.—5. Exposed to the air it rapidly changes to a vitreous mass ( $C_4H_5ClO$ ), aq.

Di-chloro-vinyl ethyl oxide  $CHCl=CCl.OEt$ . (128° cor.). S.G.  $\frac{12}{4}$  1.03. Formed by the action of NaOEt upon  $CH_2Cl.CHCl_2$  (Geuther a Brockhoff, J. pr. [2] 7, 112) or  $CClH=CCl_2$  (Paternò a. Ogialoro, B. 7, 81). Water at 180° forms glycolic acid.

Di-chloro-vinyl ethyl oxide  $CCl_2=CH.OEt$ . (145°). From  $CHCl_2.CHCl.OEt$  and conc. aqueous KOH (Godefroy). Sweet-smelling oil. Reduces ammoniacal  $AgNO_3$ , forming a mirror. Greedily combines with Br.

Tri-chloro-vinyl ethyl oxide  $CCl_2=CCl.OEt$ . (155°) (B.); (c. 160°) (G.). S.G.  $\frac{129}{4}$  1.373;  $\frac{129}{4}$  1.235 (P. a. F.);  $\frac{12}{4}$  1.332 (G.).

**Formation.**—1. From  $CCl_2=CCl_2$  and NaOEt at 110° (Geuther a. Fischer, J. 1864, 316).—2. From  $CCl_2=CHCl.OEt$  and conc. aqueous KOH (Paternò a. Pisati, G. 2, 333; Godefroy, C. R. 102, 889; Busch, B. 11, 446). Smells like mint. Br forms  $CCl_2Br.CClBr.OEt$  [17°]. Cl gives  $C_2Cl_4.O.C_2H_5$ .

**CHLORO-DI-VINYL-METHANE** v. Di-CHLORO-VALENTYLENE.

**HEXA-CHLORO-DI-VINYLOXIDE**  $C_6Cl_6O$  i.e.  $(CCl_2=CCl)_2O$ . Chloroethose. (210°). S.G.  $\frac{21}{4}$  1.652. From  $(C_2Cl_3)_2O$  and alcoholic  $K_2S$  (Malguti, A. Ch. [3] 16, 19). Br forms  $C_6Cl_6Br.O$  [96°].

**CHLOROX.** v. CHLORO-OX.

**CHLOROXAL.** v. CHLORO-OXAL.

**CHLOROXETHOFE** v. HEXA-CHLORO-DI-VINYLOXIDE.

**CHLOROXY.** v. CHLORO-OXY.

**CHLORO-O-XYLENE**  $C_6H_4(CH_2)_2Cl$  [1:2:3]. Mol. w. 140.5. (190° cor.). Fluid at –10°. Formed, together with the (1:2:4)-isomeride, by chlorination of o-xylene in presence of 5 p.c. of iodine. By dilute  $HNO_3$  it is oxidised to chloro-toluic acid [154°], which by  $KMnO_4$  is further oxidised to chloro-phthalic acid [181°] (Krüger, B. 18, 1756).

Chloro-o-xylene  $C_6H_4(CH_2)_2Cl$  [1:2:4]. (192° cor.). Fluid at –20°. S.G.  $\frac{11}{4}$  1.6692. Formed, together with the (1:2:3)-isomeride, by chlorination of o-xylene in presence of 5 p.c. of iodine. By dilute  $HNO_3$  it is oxidised to two isomeric chloro-toluic acids [166°] and [180°], which by

further oxidation with  $KMnO_4$  yield chloro-phthalic acid [180°–184°] (Krüger, B. 18, 1756).

Chloro-o-xylene  $C_6H_4(CH_2)_2Cl$ . (205° uncor.). S.G.  $\frac{12}{4}$  1.0863. Colourless, strongly refractive liquid. According to Claus a. Kautz (B. 18, 1367) this is the only chloro-o-xylene formed by chlorination of o-xylene in the cold in presence of iodine. It is readily oxidised by dilute  $HNO_3$  to chloro-phthalic acid.

Chloro-m-xylene  $C_6H_4(CH_2)_2Cl$  [1:3:4]. (186° cor.). S.G.  $\frac{32}{4}$  1.0598. Fluid at –20°. Formed by chlorination of m-xylene in presence of 5 p.c. of iodine. By  $K_2CO_3$  and  $H_2SO_4$  it is oxidised to chloro-m-toluic acid  $C_6H_4(CH_2)_2Cl.CO_2H$  [3:4:1] of melting-point [210°] (Jacobsen, B. 18, 1760; cf. Vollrath, Z. 1866, 488).

Chloro-p-xylene  $C_6H_4(CH_2)_2Cl$  [1:4:2]. [+2°]. (186° cor. at 767 mm.). Formed by chlorination of p-xylene in presence of I (Kluge, B. 18, 2099).

ω-Chloro-o-xylene  $C_6H_4(CH_2)(CH_2Cl)$  [1:2]. (198°).

**Formation.**—1. By chlorinating boiling o-xylene (Reyman, Bl. [2] 26, 534).—2. By heating  $C_6H_4(CH_2)(CH_2OH)$  [1:2] with conc. HCl. It cannot, however, be obtained pure in this way (Colson, A. Ch. [6] 6, 117).

**Reaction.**—Boiling aqueous  $Pb(NO_3)_2$  gives o-toluic aldehyde.

ω-Chloro-m-xylene  $C_6H_4(CH_2)(CH_2Cl)$  [1:3]. So-called m-Tolyl chloride. (196°). S.G.  $\frac{21}{4}$  1.079.

**Formation.**—1. From C<sup>6</sup> and boiling m-xylene (Vollrath; Lauth a. Grimaux, Bl. [2] 7, 233; A. 145, 115; Gundelach, C. R. 82, 1444).—2. By the action of HCl upon  $C_6H_4(CH_2)(CH_2OH)$  [1:3] (Colson, A. Ch. [6] 6, 118).

ω-Chloro-p-xylene  $C_6H_4(CH_2)(CH_2Cl)$  [1:4]. (192°). From Cl and boiling p-xylene (L. a. G.).

Di-chloro-o-xylene  $C_6H_4(CH_2)_2Cl_2$ . [3°]. (227°). Colourless strongly refractive liquid. Formed by chlorination of o-xylene in the cold in presence of iodine. It is readily oxidised by dilute  $HNO_3$  to di-chloro-phthalic acid [183°] (Claus a. Kautz, B. 18, 1367).

Di-chloro-m-xylene  $C_6H_4(CH_2)_2Cl_2$ . (252°). From m-xylene and Cl in presence of iodine (Hollemann, Z. 1865, 554; A. 144, 268). White laminae; melts by the heat of the hand.

Di-chloro-p-xylene  $C_6H_4(CH_2)_2Cl_2$  [1:4:2:5]. [71°]. (221° i. v.).

**Formation.**—1. By chlorination of p-xylene. 2. From chloro-p-xyldine [92°] by diazotisation and treatment with  $Cu_2Cl_2$  (Kluge, B. 18, 2098). Plates or flat needles. V. sol. hot alcohol and ether, sl. sol. cold alcohol.

ω-Di-chloro-o-xylene (1,2)  $C_6H_4(CH_2)_2Cl_2$  [55°]. (240°). S.G.  $\frac{21}{4}$  1.393. S.H. (15° to 40°) 283.

**Formation.**—4. By the action of HCl on ω-di-ox-y-xylene (Hessert, B. 12, 648; Colson, Bl. [2] 43, 7).—2. By heating o-xylene (10 c.c.) with  $PCl_5$  (35 g.) at 180°–200° (Colson a. Gautier, Bl. [2] 45, 6; C. R. 101, 1064; 104, 428; Strassmann, B. 21, 578).

**Properties.**—White crystals; v. sol. ether, alcohol, ligroin, and chloroform. Converted by heating with water into  $C_6H_4(CH_2OH)_2$  [62°]. Potassium phthalimide reacts with formation of  $CH_2Cl.C_6H_4.CH_2.N:C_6H_4.O$  [140°] (Strassmann, B. 21, 578).

Di-chloro-o-xylene  $C_6H_4(CH_2)(CH_2Cl)_2$  [103°]. (225°). From Cl and boiling o-xylene (Reyman, Bl. [2] 26, 534)

**Di-chloro-*m*-xylene**  $C_6H_4(CH_2Cl)_2$  [1.3]. [84°]. [258°]. S.G.  $\frac{2}{1}$  1.302. S.H. (15° to 40°) 295.

**Formation.**—1. From  $C_6H_4(CH_2OH)_2$  [1.3] and HCl (Colson, *Bl.* [2] 43, 7). By heating *m*-xylene at 180° with the equivalent amount of  $PCl_5$ . The yield is not so good as with the *o*- and *p*-compounds, and to obtain it pure it is necessary to saponify the crude product and treat the glycol so produced with HCl (Colson a. Gautier, *Bl.* [2] 45, 6; *A. Ch.* [6] 6, 114).

**Di-*o*-chloro-*p*-xylene**  $C_6H_4(CH_2Cl)_2$  [1.4]. 100°. (240°–250°). S.G.  $\frac{2}{1}$  1.417. S.H. (15° to 40°) 282.

**Formation.**—1. From Cl and boiling *p*-xylene (Lauth a. Grimaux, *A.* 145, 115).—2. From  $C_6H_4(CH_2OH)_2$  [1.4] and HCl.—3. By heating *p*-xylene at 180° with the equivalent amount of  $PCl_5$  (Colson a. Gautier, *Bl.* [2] 45, 6).

**Properties.**—Tables (from alcohol). Heated with water it gives the glycol  $C_6H_4(CH_2OH)_2$ . [118°] (Grimaux, *C. R.* 70, 1363).

**Tri-chloro-*o*-xylene**  $C_6H_3(CH_2Cl)_3$ . [93°]. [265° uncor.]. Formed by chlorination of *o*-xylene in the cold in presence of iodine (Claus a. Kautz, *B.* 18, 1367). Long colourless glistening needles. V. sol. ether, benzene, hot acetic acid, and hot alcohol, v. sl. sol. cold alcohol. It is readily oxidised by dilute  $HNO_3$  to tri-chlorophthalic acid, the anhydride of which melts at [157°].

**Tri-chloro-*m*-xylene**  $C_6H_3(CH_2Cl)_3$ . [150°]. [255°]. From *m*-xylene and Cl in presence of iodine (Holleman, *A.* 144, 270). Silky needles: v. sol. hot, sl. sol. cold, alcohol.

**Tetra-chloro-*o*-xylene**  $C_6H_2(CH_2Cl)_4$ . [215° uncor.]. Formed by chlorination of *o*-xylene in the cold in presence of iodine (Claus a. Kautz, *B.* 18, 1367). Sublimable. Long colourless needles. Not volatile with steam. Sol. ether, benzene, hot acetic acid, and hot alcohol, sl. sol. cold alcohol. It is not oxidised by heating with  $HNO_3$ .

**Tetra-chloro-*p*-xylene**  $C_6H_2(CH_2Cl)_4$ . [1.2]. 86° (C. a. G.); [89°] (H.). (271°). S.G.  $\frac{2}{1}$  1.601. 3. (ether) 50 at 15°; 100 at 35°. S.H. (15°–60°) 24.

**Formation.**—1. From Cl and boiling *o*-xylene (Hjelt, *B.* 18, 2879).—2. From  $PCl_5$  and *o*-xylene at 150° (Colson a. Gautier, *Bl.* [2] 45, 10).

**Properties.**—Triclinic crystals (from ether)  $a:b:c = .972:1:1.741$ ;  $\alpha = 54^\circ 38'$ ;  $\beta = 54^\circ 20'$ ;  $\gamma = 58^\circ 24'$ . Its solubility in petroleum ether is double that of the *p*-compound. Sol.  $C_6H_6$ ,  $CHCl_3$ , and alcohol. Water at 170° converts it into phthalide.

**Tetra-*o*-chloro-*m*-xylene**  $C_6H_2(CHCl)_4$ . (273°). S.G. 1.536 (Colson a. Gautier, *Bl.* [2] 45, 509).

**Tetra-*o*-chloro-*p*-xylene**  $C_6H_2(CHCl)_4$ . [1.4]. [93°]. S.G.  $\frac{2}{1}$  1.606. S.H. (15° to 60°) 242. S. (ether) 50 at 35°; S. (ligroin) 7. Formed by heating *p*-xylene (5½ c.c.) and pure  $PCl_5$  (40 g.) at 195°, and crystallising the product from ether (Colson a. Gautier, *Bl.* [2] 45, 9). Saponified by boiling with water gives terephthalic aldehyde  $C_6H_4(COOH)_2$  [1.4]. [114°].

**Penta-*o*-chloro-*o*-xylene**  $C_6H_3(CCl_2)(CHCl)_2$  [1.2]. [54°]. From *o*-xylene (3–2 c.c.) and  $PCl_5$  (40 g.) at 200° (Gautier a. Colson, *C. R.* 102, 689). Converted by boiling water into  $C_6H_3(CO_2H)(CHO)$ . [97°].

VOL. II.

**Hexa-chloro-*m*-xylene**  $C_6H_2Cl_6$  [1.3]. (c. 268°). From *m*-xylene and  $PCl_5$  (Colson a. Gautier, *C. R.* 102, 689). Converted by alkalis into a chlorinated acid.

**Hexa-*o*-chloro-*p*-xylene**  $C_6H_2(CCl_2)_2$  [1.4]. [111°]. Formed by heating *p*-xylene (1 mol.) with  $PCl_5$  (6½ mol.) for 10 hours at 200°. Transparent crystals. Sol. ether. Heated with a solution of NaHO, it loses all its chlorine, forming terephthalic acid (Colson a. Gautier, *Bl.* [2] 45, 507).

**CHLORO-*o*-XYLENE-SULPHONIC ACID**  $C_6H_4(CH_2)_2Cl.SO_3H$  [1:2:4:5]. Formed by sulphonation of chloro-*o*-xylene (1:2:4) (Krüger, *B.* 18, 1756). On reduction with sodium amalgam it gives *o*-xylene-sulphonic acid (1:2:4).

**Salts.**—A'Na 5aq: glistening needles or large flat prisms.—A'K: short needles.—A'Ba 4aq: long needles, sol. hot water, more sparingly in cold.

**Amide**  $C_6H_4Me_2Cl.SO_2NH_2$ : [207°]; long felted needles, sol. hot, sl. sol. cold, alcohol, v. sl. sol. water.

**Chloro-*o*-xylene-sulphonic acid**  $C_6H_3(CH_2)_2Cl.SO_3H$  [1:2:3:6]. Formed by sulphonation of chloro-*o*-xylene (1:2:3) (Krüger, *B.* 18, 1756).

**Salts.**—A'Na aq: large pearly plates.—A'K: plates.—A'Ba aq: thin glistening plates.

**Amide**  $C_6H_3Me_2Cl.SO_2NH_2$ : [199°]; fine silky needles or long prisms, sol. hot alcohol, sl. sol. water.

**Chloro-*m*-xylene-sulphonic acid**  $C_6H_3(CH_2)_2Cl.SO_3H$  [1:3:4:6]. Formed by sulphonation of chloro-*m*-xylene,  $C_6H_4(CH_2)_2Cl$  [1:3:4] (Gundelach, *Bl.* [2] 28, 343; Jacobsen, *B.* 18, 1761).

**Salts.**—A'Na aq: long fine needles, sl. sol. cold water.—A'K aq: needles, v. e. sol. water.—A'Ba very sparingly soluble small tables.

**Amide**  $C_6H_3(CH_2)_2Cl.SO_2NH_2$ . [195°]. Prisms (from alcohol).

**Chloro-*p*-xylene-sulphonic acid**  $C_6H_3(CH_2)_2Cl.SO_3H$ . Formed by sulphonation of chloro-*p*-xylene.

**Salts.**—A'Na aq: easily soluble prisms.—A'Ba aq: sparingly soluble needles (Kluge, *B.* 18, 2099).

**CHLORO-*m*-XYLIDINE**  $C_6H_4Cl.N$ . [89°]. From (2,3,1)-nitro-*m*-xylene, tin, and HCl (Tavildaroff, *Z.* 1870, 419). Crystalline.

**Chloro-*p*-xylidine**  $C_6H_4(CH_2)_2Cl.NH_2$  [1:4:2:5]. [92°]. Formed by the action of tin and HCl upon nitro-*p*-xylene (Jannasch, *Z.* 176, 55). Lamine (from water). By diazotising and treatment with cuprous chloride it yields di-chloro-*p*-xylene [71°].

**Salts.**—B'HCl 2aq. — B'H $_2$ SO $_4$  2aq. — B $_4$ H $_2$ C $_6$  2.

**Acetyl derivative**  $C_6H_4Me_2Cl.NHAc$ —[171°], colourless needles (Kluge, *B.* 18, 2098).

**CHLORO-XYLO-HYDROQUINONE** v. CHLORO-HYDRO-XYLOQUINONE.

**CHLORO-XYLOQUINONE**  $C_6H_3ClMe_2O$ , [x:1:4:2:5]. **Chloro-phlorone**. [48°]. Conc. HCl dissolves xyloquinone, but immediately a brown crystalline mass separates. This is a mixture of mono- and di-chloro-hydro-xyloquinones. If it be oxidised by  $CrO_3$  or  $HNO_3$  a mixture of mono- and di-chloro-xyloquinones is got. From alcohol the former crystallises in needles, the

latter in plates (Carstanjen, *J. pr.* [2] 23, 430; cf. V. Bad, *A.* 151, 158). Chloro-xyloquinone is converted by boiling with HCl into di-chloro-hydro-xyloquinone.

Di-chloro-xyloquinone  $C_6Cl_2Me_2O$ . [175°]. Prepared as above. Not affected by boiling HCl. **a-DI-CHLORO-o-XYLYLENE-DI-MALONIC ETHER**  $C_8H_4(CH_2Cl)(CO_2Et)_2$ . From sodium chloro-malonic ether and  $[1:2]C_6H_4(CH_2Br)_2$  (Baeyer & Perkin, *B.* 17, 452; *C. J.* 53, 14). Liquid. Alcoholic KOH gives o-phenylene-di-acrylic acid.

Di-chloro-m-xylylene-di-malonic ether  $C_8H_4(CH_2Cl)(CO_2Et)_2$ . Formed by the action of chloro-malonic ethyl ether and sodium ethylate on m-xylylene dibromide (Kipping, *C. J.* 53, 26). Thick yellowish oil.

Di-chloro-p-xylylene-di-malonic ether  $C_8H_4(CH_2Cl)(CO_2Et)_2$ . Formed by acting with ethyl chloromalonate and sodium ethylate on p-xylylene dibromide (Kipping, *C. J.* 53, 85). Colourless six-sided plates. Insol. water, v. sol. alcohol, ether, petroleum ether, and HOAc.

**CHLORO-DI-XYLYL-ETHANE**  $C_{12}H_{10}Cl_2$  i.e.  $CH_2Cl.CH(C_6H_4Me)_2$ . From di-chlorinated ether  $CH_2Cl.CHCl.OEt$ , xylene, and  $H_2SO_4$  (Hepp, *B.* 7, 1416). On distillation it splits up into HCl and  $CH_2C(C_6H_4Me)_2$ .

**CHOLANIC ACID** v. **CHOLIC ACID**.

**CHOLANIC ACID**  $C_{26}H_{44}O_6$  {aq. [285°] (L.). S. 025 at 100°; 011 at 20° (L.; cf. Kutscheroff, *B.* 14, 1492); S. (alcohol of 98.5 p.c. at 18°) 1.37.  $[a]_D = 53^\circ$  (T.); 88° (Kutscheroff). Formed by oxidation, with  $K_2Cr_2O_7$  and  $H_2SO_4$ , of choleic acid  $C_{26}H_{46}O_6$ , of dehydrocholeic acid  $C_{26}H_{42}O_6$ , and also (according to L.) of desoxycholeic acid (Tappiner, *A.* 194, 231; Latschinoff, *B.* 13, 1052; 18, 3045; 19, 474, 1521; 20, 1044; *Bl.* [2] 46, 818). Large tables or flat prisms. Tribasic acid. Dextro-rotatory. On further oxidation by boiling with  $HNO_3$  (1.28 S.G.), it gives choloidanic acid and pseudo-choloidanic acid.

**Salts.**— $A''Ba$  6aq: tables or plates; S. (at 18°) 4.12;  $[a]_D = +49.37^\circ$ .

**Mono-methyl ether**  $A''HMe$ : [207°]; very slender needles; v. sol. alcohol, less sol. ether; the Na, K, Ca, and Ba salts are v. sol. water and alcohol.— $A''MeBa$ .

**Mono-ethyl ether**  $A''HEt$ : [190°]; the properties are the same as those of the mono-methyl ether.— $A''EtBa$ .— $A''EtPb$ .

**Di-methyl ether**  $A''HMe_2$ : [176°]; needles.

**Di-ethyl ether**  $A''HEt_2$ : [131°].— $A''EtBa$ .— $A''EtPb$ .

**Tri-methyl ether**  $A''HMe_3$ : [121°]; needles. **Tri-ethyl ether**  $A''HEt_3$ : [76°]; needles.

**Iso-cholanic acid**  $C_{26}H_{44}O_6$  (?) [248°].

$[a]_D = 73.3^\circ$ . S. 022; S. (alcohol) 9.1; S. (ether) 018. Formed in small quantity, together with cholanic acid, by oxidation of choleic acid, with  $K_2Cr_2O_7$  and  $H_2SO_4$  (Latschinoff, *B.* 15, 713; 19, 1529). The cholanic acid described by Tappiner appears to be contaminated with a small quantity of this isomeric acid.\* Pearly plates. Penta-basic acid.

**Salts.**— $A''K_5$ : soluble hair-like needles.— $A''KH_5$ : fine needles.— $A''Ba$ , 10aq?: sparingly soluble amorphous powder.— $A''BaH$ .— $A''Pb$ , 6aq: amorphous pp., insol. water and

alcohol.— $A''Ag$ : insoluble amorphous pp.— $A''Cu$ ,  $Cu_2O$ , 10aq: amorphous blue pp.

**Methyl ether**  $C_{26}H_{44}O_6Me$ : [186°]; plates. From the lead salt and MeI.

**Ethyl ether**  $C_{26}H_{44}O_6Et$ : [43°–50°]; flat needles.

**CHOLECAMPHORIC ACID** v. **CHOLOIDANIC ACID**.

**CHOLEIC ACID**  $C_{26}H_{46}O_6$  (?). [185°–190°]. S. (water at 20°) 0045; (75 p.c. alcohol at 20°) 4; (absol. alcohol at 20°) 7.1; (absol. ether at 20°) 133. With 300 mm. of a 6.06 p.c. solution in absol. alcohol at 20°,  $[a]_D = 56.40^\circ$ . From alcohol or acetic acid it crystallises in hemihedral rhombic needles,  $a:b:c = 1:5057:1.8598$ . Occurs in saponified ox-gall together with cholic and desoxycholic acids. It gives Pettenkofer's test for bile acids (Mylus, *H.* 11, 492). On gentle oxidation with  $CrO_3$  and acetic acid it is converted into dehydrocholeic acid  $C_{26}H_{42}O_6$ , by more vigorous oxidation, with  $K_2Cr_2O_7$  and  $H_2SO_4$ , into cholanic acid (but no bilianic acid). According to Latschinoff by boiling with glacial acetic acid it is converted into desoxycholic acid (called by him 'hydrated choleic acid'); Mylius, however, was unable to confirm this statement.

**Salts.**— $A''Ag$ .— $A''Ba$ : microscopic plates, insol. strong alcohol and water, v. sol. dilute alcohol forming the hydrated salt.— $A''Ba$  6aq: needles, v. sol. dilute alcohol, S. (water at 20°) 083 (Latschinoff, *Bl.* [2] 46, 817; *B.* 18, 3039; 19, 1140; 20, 1043, 1053; Mylius, *B.* 19, 869; 20, 1968).

Dehydrocholeic acid  $C_{26}H_{42}O_6$  (?) according to L. [183° uncor.]. Obtained by slowly adding a 10 p.c. solution of  $CrO_3$  (3 pts.) in acetic acid to a 10 p.c. solution of choleic acid (4 pts.) in acetic acid; the yield is 60 to 70 p.c. According to L. it is also formed by similar treatment from desoxycholic acid. Silky tables. Less soluble in water and alcohol than dehydrocholic acid. By further oxidation with  $K_2Cr_2O_7$  and  $H_2SO_4$ , it yields cholanic acid.— $A''Ba$  13aq: needles, v. sol. alcohol, sl. sol. water (Latschinoff, *B.* 18, 3045; 20, 1044).

**CHOLESTERIN** (*Animal cholesterin*)

$C_{26}H_{44}O$ , aq. or  $C_{26}H_{42}O$ , aq. or  $C_{26}H_{40}O$ , aq. [146°, Hesse] [147.5°, or cor. = 148.5°, Reinitzer] [usually given at 145° to 140°].<sup>1</sup>  $[a]_D$  for anhydrous cholesterol from gallstones in chloroform =  $(-36.61 + 0.249 p.)$  (O. Hesse). This rotation depends to some extent on the strength of the solution. S.G.  $\frac{20}{4}$  1.046 (Mehu, *J. Ph.* [4] 20, 175); 1.067 (Hoppe-Seyler, *Gmelin's Handb.*, 18, 113); 1.03 after fusion (Hein, *ibid.*).

**Occurrence.**—This substance was first obtained by Conradi in 1755 from human gallstones, of which it sometimes constitutes nearly the entire substance. It has been found in human bile (Chevreul, *A. Ch.* 95, 5; 96, 166); in the blood (Lecanu, *A. Ch.* 67, 54; Boudet, *ibid.* 336; Denis, *J. Chim. Med.* [2] 4, 161; Becquerel & Bodier, *Gaz. Med.* 47); together with protagon as an essential constituent of the nervous tissue, of the yolk of egg, of the seminal fluid, and of the red and white corpuscles of the blood (Hoppe-Seyler, *Med. Chem.*

<sup>1</sup> When cholesterolin is mixed with iso-cholesterin, the melting point is lowered.

*Unters.* 1, 140; *J.* 1866, 744; in the brain (Courbe, *A. Ch.* 56, 281; Framy, *ibid.* [3] 11, 486; Beneke, *Bied. Centr.* 1881, 568)—the brain of a boy 15 years old was found to contain 26.92 g. cholesterol = 2.34 p.c., that of a woman 19 years old, 26.79 g. = 2.12 p.c. (Beneke); in the yolk of egg (Lecand, *J. Ph.* 15, 1; Gobley, *ibid.* [3] 12, 12—four hen's eggs yielded 0.692 g., and four newly hatched chickens 0.41 g. (Beneke); in oxen bile (Hüfner, *J. pr.* [2] 19, 305); in human milk to the amount of 0.0318 p.c. (Tolmatscheff, *Med.-Chem. Unters.* 1, 272); in cow's milk (Schmidt a. Mülheim, *Archiv f. d. ges. Physiol.* 25, 384); in the spleen, and abundantly in the excrements of the crocodile (Marcet, *A. Ch.* [3] 59, 91); in guano (Hoppe-Seyler, *J.* 1863, 654); in the corpus luteum of the cow (Lieben, *Z.* 4, 646); along with paracholesterolin in the protoplasm of *ethalium septicum* (Reinke a. Rodewald, *A.* 207, 228); along with iso-cholesterin in the grease of sheep's wool (Hartmann, *Inaug. Dissert. Göttingen*, 1863; E. Schulze, *Z.* [2] 6, 453); and in certain morbid products of the animal economy, such as cerebral concretions, scirrhus matter of the mesocolon, hydropic liquid of the abdomen, ovaries, testicles, &c. (Lassaigne, *A. Ch.* 9, 324; O. Henry, *J. Chim. Med.* 1, 280; Cavenou, *J. Ph.* 11, 462; Lehmann, *Lehrb. d. Physiol. Chem.* 2te Aufl. 1, 286).

The first exact analysis of cholesterolin was made by Chevreul, who assigned to it the formula  $C_{26}H_{44}O$ . Its metamorphoses have been studied by Marchand (*J. pr.* 16, 37); Rodtenbacher (*A.* 57, 145); Meissner a. Schwendler (*ibid.* 59, 107, also *J. pr.* 39, 247); Zwenger (*A.* 66, 5; 69, 347); Heintz (P. 79, 524); Berthelot (*A. Ch.* [3] 56, 51); and by others, who will be referred to in the course of this article.

**Preparation.**—1. By crystallising biliary calculi from boiling alcohol, to which a little potash is added to dissolve any fatty acids that may be present. 2. By extracting brain substance with ether, and boiling the evaporated extract with alcoholic potash. 3. From the grease of sheep's wool by saponifying for 20 hours at  $100^{\circ}$  with alcoholic potash in a closed stoneware bottle, evaporating the alcohol, taking up with water and shaking with ether. The residue from the evaporation of the ether consists of a mixture of cholesterolin, iso-cholesterin, and a nearly-related amorphous alcohol poorer in carbon,<sup>2</sup> and these are best separated from one another by conversion into their benzoic ethers, by fusing the mixture of alcohols (2 parts) with benzoic anhydride (1 part) to about  $180^{\circ}$  for 48 hours. The resulting mass is rubbed up with a little alcohol in a mortar, treated first with a cold solution of  $Na_2CO_3$ , and then with warm water to extract the benzoic acid formed

<sup>2</sup> This amorphous alcohol, which is poorer in carbon than cholesterolin, is v. sol. cold alcohol, ether, and acetone, but it has not yet been obtained pure, in fact there is as yet no guarantee that it is a chemically simple substance. It has a weak, aromatic odour, and melts at a gentle heat. It appears to be present in the fat, partly free and partly combined with acids, chiefly oleic. The greater portion of wool-fat consists of compound ethers, but a portion of the alcohols—at least of the cholesterolins—and also sometimes a portion of the acids are present in the free state. The formation of potash soaps in wool-fat is now readily explained by the presence of free fatty acids on which the  $K_2CO_3$  can act; a portion of the compound ethers may, however, be decomposed also (Schulze a. Ulrich, *J. pr.* [2] 3, 321).

and the excess of anhydride, and then dried. To the mixture cold ether is now added, in which the benzoate of the amorphous alcohol is readily soluble, those of cholesterolin and iso-cholesterin dissolving only slightly. The two latter may then be separated by slow recrystallisation from ether and elutriation, cholesterolin benzoate crystallising in plates, and iso-cholesterin benzoate in needles. The benzoates are then separately saponified for their respective cholesterolins, which are recrystallised for further purification (E. Schulze, *J. pr.* 7, 163).—4. On adding ether and HCl to fresh oxen bile, the cholesterolin is obtained in the ethereal layer (Hüfner, *J. pr.* [2] 19, 305).

**Properties.**—Monatomic alcohol. Laminated transparent crystals of  $C_{26}H_{44}O$ , aq. (from a mixture of alcohol (3 vols.) and ether (1 vol.)), which give off their water at  $100^{\circ}$ . Plates (containing aq.) (from alcohol and ether). Anhydrous needles (from chloroform). Tasteless and inodorous. Insol. water, v. sol. hot, sl. sol. cold, alcohol, v. sol. ether, chloroform, carbon bisulphide, oil of turpentine, soap water, and neutral fats, &c.

**Reactions.**—(a) Sublimes at  $200^{\circ}$ , but decomposes at a higher temperature. (b) Resists the action of conc. alkaline solutions, even at the boiling temperature, but is decomposed by lime at about  $250^{\circ}$ , with evolution of hydrogen and formation of an amorphous body nearly insoluble in alcohol. (c) For the action of halogens v. Derivatives. (d) Yields with conc.  $H_2SO_4$ , a. b. and c. Cholesterilins (v. these) (Zwenger). (e) Yields with conc.  $H_3PO_4$  (a) and (b) Cholesterones (q. v.).

**Characteristic tests.**—(a) When a few centigrammes are dissolved in chloroform and the solution is shaken up with an equal volume of  $H_2SO_4$  (best of 1.75 S.G.), the chloroform layer, at first yellow-brown, soon becomes blood-red, and then cherry-red or purple, the colour remaining for some hours if the solution is in a closed bottle, i.e. if air be not admitted; it then becomes blue, green, and finally yellow. The sulphuric acid at the same time shows a fine green fluorescence (Hesse, *A.* 211, 283; Reinke a. Rodewald, *A.* 207, 229; Salkowski, *C. C.* 1873). (b) When a small quantity is evaporated at a gentle heat with a drop of nitric acid, a yellow spot is left, which turns red when touched with a drop of ammonia, and the red colour thus produced is not essentially altered by subsequent addition of fixed alkali, thus distinguishing this from the corresponding reaction with uric acid (Schiff, *A.* 115, 113). (c) When slowly evaporated to dryness with 3 vols. conc. HCl or  $H_2SO_4$ , and 1 vol.  $FeCl_3$  solution, the particles remaining undissolved assume a violet-red colour, changing to bluish-violet at a somewhat higher, and dull-grey at a still higher, temperature. This reaction, which is likewise produced with  $AlCl_3$ ,  $PtCl_4$ , or  $K_2Cr_2O_7$  + HCl, is not exhibited by the colouring matter or any other constituent of the bile (Schiff).

**Applications.**—Cholesterolin possesses the property of absorbing more than 100 p.c. of water (Lieblich, *cf. C. S. I.* 5, 573), a point of great therapeutic moment. The grease of sheep's wool is now therefore being purified in quantity, and the manufactured product, which is termed 'lanolin,' used as a basis for ointments, &c.

Cholesteryl chloride,  $C_{26}H_{49}Cl$ . [97°, Walitzky]. [96°, Raymann]. Prepared by the action of  $POCl_3$  on cholesterol or its acetate. Small scales, sl. sol. alcohol, v. sol. ether. Not decomposed by aqueous, but by boiling alcoholic potash (Planer, A. 118, 25; Lindenmeyer, J. pr. 90, 321; Rayman, Bl. 2 [47, 898]).

Cholesterin dibromide  $C_{26}H_{47}OBr_2$ . Prepared by the action of bromine on cholesterol, both dissolved in  $CS_2$ . White needles (from ether-alcohol), sl. sol. alcohol, v. sol. ether. Is reconverted to cholesterol by Na amalgam (Wislicenus a. Moldenhauer, A. 146, 175).

Cholesteryl chloro-dibromide  $C_{26}H_{47}ClBr_2$ . [128°]. Prepared by gradually adding Br to an ethereal solution of cholesteryl chloride. White powder or large colourless crystals (from  $CS_2$ ). Sol. carbon bisulphide, chloroform, and ligroin (Rayman).

Nitro-cholesterin [94°]. Red-yellow mass, insol. water, sol.  $NH_4Aq$  and  $K(Na)OHAq$ , v. sol. alcohol, ether, chloroform, &c. (Reinitzer, M. 9, 421).

Di-nitro-cholesterin  $C_{26}H_{47}(NO_2)_2O$  or  $C_{26}H_{45}(NO_2)_2O$ . [121°]. Colourless needles (from alcohol). V. sol. hot alcohol and ether (Preis a. Rayman, B. 12, 224).

Nitro-cholesteryl chloride  $C_{26}H_{47}(NO_2)Cl$  or  $C_{26}H_{45}(NO_2)Cl$ . [149°]. Colourless needles (from alcohol) (P. a. R.).

Cholesteryl acetate  $C_{26}H_{47}O.C_2H_3O$  or  $C_{26}H_{45}O.C_2H_3O$ . [92°, Löbisch, B. 5, 513]; [113°, Raymann, Bl. 47] [111°–112° uncor. (chol. from gallstones), Jacobsen]; [114–5° cor.] (from gallstones) (Reinitzer, M. 9, 428).

*Preparation.*—By heating cholesterol, also sodium cholesterate, with acetic anhydride, or with acetic acid or acetyl chloride. Needles (from benzene). Trimorphous, the first modification being monosymmetric crystals, and the second monosymmetric plates with rhombic edges, while the third form has not yet been defined. Shows curious changes of colour on solidifying after fusion, which changes are not yet explained, but are apparently closely connected with the separation—during fusion—and resolution of a substance whose nature is not known (Leymann v. Reinitzer, loc. cit.).

Bromo-cholesteryl acetate  $C_{26}H_{47}Br.C_2H_3O$ . [118° cor. and 116° cor.] (Reinitzer, M. 9, 424).

Long glancing tables (from ether-alcohol). Dimorphous, the first modification being monosymmetric tables [118°], and the second asymmetric tables [116°]. Somewhat decomposed by light (Reinitzer).

Cholesteryl butyrate  $C_{26}H_{47}O.C_4H_7O$ . M. sol. hot alcohol.

Cholesteryl stearate  $C_{26}H_{47}O.C_{18}H_{35}O$ . Needles, sl. sol. cold ether, almost insol. alcohol (Berthelot).

Cholesteryl benzoate  $C_{26}H_{47}O.C_6H_5O$  or  $C_{26}H_{45}O.C_6H_5O$ . [150°–151° Schulze; 146–6° cor. Reinitzer].

*Preparation.*—See separation of cholesterol and ischolesterin (Schulze, J. pr.). Better, by heating anhydrous cholesterol (10 pts.) with benzoic anhydride (12 pts.) in an open flask to 150°–160° for 1½ hours (Reinitzer, M. 9). Beautiful small glancing tables (from ether); m. sol. ether, sl. sol. boiling alcohol (Berthelot, Schulze). Trimorphous, the first modification being tetra-

gonal crystals, the second forming rhombic needles or small plates, and the third crystallising in thin broad plates. Exhibits on fusion colour phenomena similar to those shown by the acetate, but not quite the same (Reinitzer, loc. cit.).

Sodium cholesterate  $C_{26}H_{47}NaO$ . [150°].

*Formation.*—By the action of Na on a saturated solution of cholesterol in petroleum. Silky needles (from petroleum or chloroform). Slowly decomposed by water, more quickly by alcohol (Lindenmeyer, J. pr. 90, 321).

Cholesterylamine  $C_{26}H_{47}NH_2$ . [104°] (Henry). Small plates.

Cholesteryl-aniline  $C_{26}H_{47}.C_6H_5NH$ . [187°].

*Preparation.*—By heating cholesterol chloride and aniline to 180° for 6–12 hours (Walitzky, Chem. Sect. d. Russ. phys.-chem. Ges. Oct. 1878; B. 11, 1937). Long rectangular plates (from  $CS_2$ ); m. sol. ether and boiling alcohol, v. sol. carbon bisulphide. Ppd. from ethereal solution by mineral acids.

Salts.—The  $H_2SO_4$ ,  $HNO_3$ , and  $HCl$  salts are crystalline.

Cholesteryl-*p*-toluidine  $C_{26}H_{47}NHC_6H_4$ . [173°]. Prepared at 150°–180°. Rectangular tables (from ether). Sol. alcohol, ether, and carbon bisulphide. Weak base (Walitzky).

Salts.—The  $HNO_3$  salt is much more stable than those of  $HCl$  or  $H_2SO_4$ .

Tri-oxy-cholesterin  $C_{26}H_{42}O_3$ .

*Preparation.*—(a) By saponifying the di-acetin (see below) with alcoholic potash, dissolving the residue in water and ppg. by an acid (Latschinoff, Chem. Sect. d. Russ. phys.-chem. Ges., Oct. 1878; B. 11, 1941).

(b) By oxidising a solution of cholesterol in  $HOAc$  by  $KMnO_4$ ; this latter method does not yield it quite pure.

*Properties.*—Yellowish powder. Sol. alcohol, ether, and  $KOHAq$ . Mol. w. not yet determined. Resembles phenol in behaviour.

Di-acetyl derivative  $C_{26}H_{40}O(C_2H_3O)_2$ . [77°].

*Preparation.*—Cholesterol acetate is oxidised by  $KMnO_4$ , and the di-acetin dissolved out of the resulting mass by ether (Latschinoff).

*Properties.*—White hard powder, indistinctly crystalline, obtained on adding water to the  $HOAc$  solution. V. sol. glacial acetic acid, alcohol, ether, benzene, &c., but not crystallisable from any one of these.

Cholesterilline *a*, *b*, and *c*  $C_{26}H_{47}$  or  $C_{26}H_{45}$  (Zwenger, A. 66, 5; 69, 347).

*Preparation.*—By acting with conc.  $H_2SO_4$  on a slightly heated mixture of cholesterol and dilute sulphuric acid.

*Properties.*—(a) [240°]. Amorphous. Insol. water, almost insol. alcohol, v. sl. sol. ether. (b) [255°] shining scales. Insol. water, m. sol. hot ether. (c) [227°]. Resinous. Insol. water, sol. hot ether.

Walitzky's *Cholestene*  $C_{26}H_{42}$ , obtained by heating cholesterol with sodium to 150°–155°, appears to be identical with *c*, also with the compound obtained by acting on cholesterol with  $HI$  (S.G. 1-5), or by heating it with soda-lime up to 250°. Cholestene and the two last give, with excess of Br, the same compound  $C_{26}H_{41}Br$  (Walitzky, C. R. 92, 195).

T. Weyl (Archiv f. Anat. und Physiol. 1, 182) has studied these compounds anew, and

considers that they agree with the formula  $(C_2H_5)_2H_2O$ . For the relations between cholesterolin, cholic acid, and the terpenes, see Latschinoff, Walitzky, and Weyl.

Cholesterones  $C_{26}H_{48}O$  or  $C_{26}H_{46}O$ . When cholesterolin is boiled with excess of conc. phosphoric acid it forms two compounds,  $\alpha$ - and  $\beta$ -cholesterone, isomeric with each other, but differing in physical properties (Zwenger, A. 69, 347).

**$\alpha$ -Cholesterone.** [68°]. Rectangular prisms, v. sol. alcohol and ether, and distilling without decomposition.

**$\beta$ -Cholesterone** [175°]. Small silky needles, almost insol. alcohol, sl. sol. ether.

**Cholesteric acid**  $C_{26}H_{48}O_2$ .

**Formation.**—By the oxidation of cholic acid  $C_{26}H_{48}O_2$  or  $(C_{26}H_{46}O)_2$ , by  $K_2Cr_2O_7$  (10 parts) and  $H_2SO_4$  (15 parts). The acid must be diluted with at least three times its volume of water before the oxidation, and the latter interrupted as soon as the cholesteric acid is formed, otherwise it is obtained mixed with pyro-cholesteric acid (see below). Redtenbacher's cholesteric acid  $C_{26}H_{48}O_2$  (A. 57, 160) is such a mixture. The filtered solution must be concentrated at a low temperature, unless the  $H_2SO_4$  is first neutralised. The cholesteric acid crystallises, and is purified either by washing with a little cold water or by recrystallisation from ether (Tappeiner, A. 194, 211; B. 12, 1627; Latschinoff, B. 12, 1518).

**Properties.**—Tribasic acid. Needles (from water and alcohol), long prisms (from ether containing some water). V. sol. hot water. Not volatile with steam. Slightly dextro-rotatory in alcoholic solution. Gives no colouration with sugar and  $H_2SO_4$ , and has not the toxic action of cholic acid. Its power of crystallisation is greatly diminished by the presence of small quantities of the pyro-acid.

**Salts.**—The Ca and Ba salts are less sol. hot than cold water. At 100° they generally go into salts of pyro-cholesteric acid (Tappeiner).  $A''Ba$ ,  $A''Ag$ ,  $A''HAg$ .

**Pyro-cholesteric acid**  $C_{11}H_{18}O_2$ . [108°].

**Preparation.**—(a) Best by heating a solution of cholesteric acid in glycerin for 5 to 8 days at 198°, saponifying the glycerates, distilling off small quantities of volatile acids, such as propionic, and extracting with ether (Tappeiner). (b) Also by boiling with  $H_2SO_4$  diluted with 3 vols. water, but in this case the decomposition goes further.

**Properties.**—Gummy mass, sol. water, alcohol, and ether.

**Iso-cholesterin**  $C_{26}H_{48}O$ . [138°–138.5°]. [ $\alpha$ ], in ethereal solution + 60° (Schulze, J. pr. [2] 7, 163; Schulze a. Ulrich, J. Pr. [2] 9, 321; Schulze, B. 12, 249).

**Occurrence.**—In the fat of sheep's wool.

**For Preparation and separation from cholesterolin, see the latter.**

**Properties.**—Flocks (from dilute alcoholic solution), a jelly (from concentrated alcoholic solution), fine transparent needles (from ether or acetone). Sl. sol. cold, v. sol. hot, alcohol, ether, and acetone, i.e. solubility is very much the same as that of cholesterolin. A mixture of cholesterolin and iso-cholesterin melts at a lower temperature than either separately.

**Reactions.**—(a) The  $CHCl_3$  and  $H_2SO_4$  test gives only a very feeble colouration (Schulze,

J. pr. [2] 7, 163). (b) The  $HNO_3$  and  $NH_3$  test gives the same colouration as cholesterolin.

**Iso-cholesterin derivatives.**

**Iso-cholesteryl chloride**  $C_{26}H_{47}Cl$ . Prepared by the action of  $PCl_5$  on iso-cholesterin. Amorphous. V. sol. ether, sl. sol. alcohol.

**Acetyl derivative** [below 100°]. Amorphous; sl. sol. alcohol.

**Stearyl derivative** [72°]. Fine white needles (from ether). V. sl. sol. alcohol.

**Benzoyl derivative**  $C_{26}H_{45}O.C_6H_5O$ . [190°–191°]. Fine needles (from ether). Sl. sol. alcohol, m. sol. acetone, v. sol. ether.

**Phytosterin**  $C_{27}H_{48}O$ , aq. [132–133°] (Hesse, A. 192); [133°] (v. Lippmann, B. 20, 3201); [133°] Paschkis, H. 8, 356; [132°], [135°], [133°], and [136°], Jacobsen; [136–137°], Beneke; [136–137°] Schulze a. Barbieri (from lupines), J. pr. [2] 25, 159. [ $\alpha$ ], (anhydrous in  $CHCl_3$ )

= –34.2° (Hesse)

= –33.7° and –35.1° (v. Lippmann)

from –30.4 to –33.4 (Jacobsen)

–32.7° (Paschkis)

–32.5° in ether (Lindenmeyer)

–36.4° (Schulze a. Barbieri).

Those who first isolated phytosterin considered it to be cholesterolin. The name phytosterin was given to it by Hesse.

**Occurrence.**—In peas and olive oil (Beneke, A. 122, 249; Knop, C. C. 1862, 819); calabar beans (Hesse, A. 192, 176); in the seeds and cotyledons of the shoots of the yellow lupine, '*Lupinus luteus*' (Schulze a. Barbieri, J. pr. [2] 25, 159); in almonds; mustard seed; Bookshorn seed; in numerous fungi, e.g. *Polyponis officinalis* (Schmieder, C. C. 86, 774); in the seed oil of rape, lentils, almond, cotton, earth nut or pea nut, poppy, and cocoa (Salkowski, Z. f. Anal. Chem. 26, 557); together with cholesterolin in butter and ood-liver oil (Salkowski); in hog's beans and vetches (Jacobsen); in the juice of beet (v. Lippmann, B. 20, 3201); in wheat gluten (Ritthausen, J. pr. 85, 212; 88, 145); in maize grains (Hoppe-Seyler, Kri. Zeit. 10, 32); in barley fat (Stellwaag, Zeitschr. f. d. g. Brauereis. 1886, 176; Chem. Zt., Chem. Repert. 10, No. 23); in the fat of meadow hay and of oat straw (König, Landw. Versuchstationen, 17, 3, 11); in colchicum seeds (Paschkis, H. 8, 356); in the oil of the seeds of *Chaunmoogra* (*Gynocardia odorata*, Roxb.), of *Jacquirity* (*Abrus precatorius* Lam.), and in the fat of the leaves of *Erythroxylum hypericifolium* Lam. (Heckel a. Schlagdenhauffen, C. R. 102, 1087); probably also in the animal body, possibly together with cholesterolin, as may be deduced from older observations (Gmelin, Handb. 4, 2092).

**Preparation.**—(a) From peas (Beneke, loc. cit.).

(b) From calabar beans. These are extracted with petroleum ether. When this is evaporated, a fatty oil is left, out of which phytosterin crystallises. It is separated from the oil by pressure, purified by dissolving in ether with bone black, and recrystallised from alcohol (Hesse, A. 192, 176).

(c) From beans. The powdered beans are extracted with alcohol, the alcohol distilled, and the residue extracted with ether. This extract

<sup>1</sup> It is possible that in some of the cases here mentioned a cholesterolin other than phytosterin is present.

saponified with 25 p.c. NaOH, and the layer of fat separated from the deep-coloured mother liquor. The fat, purified from glycerin, is then extracted with ether, and the phytosterin obtained from this ether extract (Jacobsen, *Inaug. Dissert.* Königsberg in Preussen, 1887).

(d) From the powdered seeds and shoots of the yellow lupine (Schulze & Barbieri, *J. pr.* [2] 25, 159). The finely powdered seeds and shoots are extracted with ether, the extract distilled, and the residue boiled for several hours with alcoholic potash, using a reflux condenser. The solution thus obtained is evaporated, the residue rubbed up with water and shaken with ether several times. The ether is then distilled off, and the residue dissolved in the least possible quantity of hot alcohol. On cooling, the phytosterin crystallises out. It may then be purified by conversion into the benzoate, re-saponification of this with alcoholic potash, and re-crystallisation from alcohol.

(e) Reinitzer recommends the following method for the separation of cholesterol from fats (*M.* 7, 597). The juice—e.g. of carrots—is ppd. with  $\text{PbAc}_2$ , the pp. dried, and—together with the pressed vegetable—extracted by carbon bisulphide. The residue after distillation of the bisulphide is saponified with alcoholic potash, the alcohol evaporated, the mass taken up with water and ppd. by  $\text{BaCl}_2$ , and the washed and vacuum-dried pp. extracted by acetone.

**Properties.**—Glittering plates of  $\text{C}_{26}\text{H}_{44}\text{Oaq}$  (from alcohol), silky needles of  $\text{C}_{26}\text{H}_{44}\text{O}$  (from chloroform, ether, and petroleum ether). Insol. water or KOH aq, v. sol. hot alcohol, ether, and chloroform. A mixture of phytosterin (from lupines) and cholesterol crystallises from alcohol in a mass of small needles, i.e. in a form different from that of either separately.

**Reactions.**—(a) The  $\text{CHCl}_3$  and  $\text{H}_2\text{SO}_4$  test gives exactly the same results as with cholesterol and quebrachol (Hesse, *A.* 211, 283).

(b) Cautiously evaporated with  $\text{HCl}$  and  $\text{Fe}_2\text{Cl}_6$ , it gives a violet colour like ordinary cholesterol.

**Acetyl derivative**  $\text{C}_{26}\text{H}_{42}\text{O}(\text{C}_2\text{H}_3\text{O})$  or  $\text{C}_{28}\text{H}_{44}\text{O}(\text{C}_2\text{H}_3\text{O})$ . [126°, Hesse]. [126°, 120°, 118°, and 125° uncor., Jacobsen]. Glancing plates (from alcohol) (Hesse). Resembles in its properties the acetates of cupreol and quebrachol (H.). Prismatic needles (from alcohol) (Jacobsen). Sl. sol. alcohol, v. sol. ether and chloroform.

**Benzoyl derivative** [145.5°, 147°, 146°, and 145° uncor., Jacobsen]. Thin glancing rectangular plates (from ether), sl. sol. alcohol, m. sol. ether and chloroform. Gives the colour reactions with  $\text{CHCl}_3$  and  $\text{H}_2\text{SO}_4$  and with  $\text{Fe}_2\text{Cl}_6$ , but not with  $\text{HNO}_3$  and  $\text{NH}_3$  (Jacobsen).

**Hydrocarotin**  $\text{C}_{26}\text{H}_{44}\text{Oaq}$ ? [136.5°]  $[\alpha]_D$  (in  $\text{CHCl}_3$ ) - 85° (Arnaud, *C. R.* 102, 1319; also 100, 761). [138.2°].  $[\alpha]_D$  (in  $\text{CHCl}_3$ ) - 37.4 (Reinitzer, *M.* 7, 579). This substance is probably phytosterin, although Reinitzer considers that it more nearly resembles Liebermann's cholestol (oxyquinoterpene)  $\text{C}_{26}\text{H}_{44}\text{O}_2$ ? [139°], which latter, in its turn, Hesse looks on as being probably almost pure cinchol.

**Occurrence and preparation.**—In and from carrots.

**Properties.**—Plates (containing aq) (from

alcohol), anhydrous needles (from the other solvents). Insol. water, sl. sol. cold, v. sol. hot alcohol, ether, chloroform, &c. Fröhde (*J. pr.* 102, 424) declared hydrocarotin to be cholesterol, which Husemann repudiated. Arnaud, however, finds that Husemann's hydrocarotin (*A.* 117, 200) is phytosterin mixed with some carotene.

**Reactions.**—Gives the cholesterol reactions with

- (a)  $\text{CHCl}_3$  and  $\text{H}_2\text{SO}_4$ ,
- (b)  $\text{HNO}_3$  and  $\text{NH}_3$ ,
- (c)  $\text{HCl}$  and  $\text{Fe}_2\text{Cl}_6$ ,
- (d) Liebermann's with  $(\text{Ac})_2\text{O}$  and  $\text{H}_2\text{SO}_4$  (*B.* 18, 1803).

**Acetyl derivatives.** [128.2°]. Colourless crystalline scales (from ether-alcohol). Sl. sol. hot alcohol.

**Benzoyl derivative.** [145°]. Dimetric glancing tables, when slowly crystallised from ether. V. sol. ether. (*Cf.* phytosterin.)

**Para-cholesterin**  $\text{C}_{26}\text{H}_{44}\text{Oaq}$ . [184°-184.5° uncor., R. & R.].  $[\alpha]_D$  (in  $\text{CHCl}_3$ ) - 28.88 and - 27.24 for different strengths (R. & R.).

**Occurrence.**—In the protoplasm of *Ethaliium septicum*.

**Preparation.**—*Ethaliium septicum* is digested with alcohol and the whole mass evaporated to dryness and extracted with ether. From this the *p*-cholesterin crystallises out, and is purified by crystallisation from hot alcohol, the cholesterol which is also present remaining in the alcoholic mother liquor (Reinke & Rodewald, *A.* 207, 229).

**Properties.**—Plates (containing aq) (from alcohol), silky glancing needles (from ether and chloroform). V. sol. hot alcohol, ether, and chloroform, m. sol. cold alcohol. Gives up its water over  $\text{H}_2\text{SO}_4$ . In general properties it agrees with cholesterol, iso-cholesterin, and Beneke's cholesterol from *pena*, in chemical properties it resembles Hesse's phytosterin.

**Reactions.**—The  $\text{CHCl}_3$  and  $\text{H}_2\text{SO}_4$  test gives much the same colouration as Schulze's iso-cholesterin. At first both the chloroform and sulphuric acid layers are coloured yellowish-brown, the latter with green fluorescence. On prolonged standing the chloroform becomes blue and then violet, while the acid becomes a deeper brown and the fluorescence increases (R. & R.).

**Benzoyl derivative.** [127°-128° uncor.]. Thin glancing rectangular plates (from ether). V. sol. ether and chloroform, m. sol. hot, sl. sol. cold, alcohol (R. & R.).

**Caulosterin**  $\text{C}_{26}\text{H}_{44}\text{Oaq}$ . [158°-159°].  $[\alpha]_D$  (in chloroform) - 49.6°.

**Occurrence and preparation.**—In the root and growing parts (radicles) of the shoots of the yellow lupine, '*lupinus luteus*,' from which it is extracted in the same way as the phytosterin from the seeds (Schulze & Barbieri, *J. pr.* [2] 25, 159).

**Reaction.**—a. With  $\text{CHCl}_3$  and  $\text{H}_2\text{SO}_4$  it behaves in the same way as cholesterol and phytosterin.

**Benzoyl derivative.**—Thin glancing plates (from ether).

It will be seen from the foregoing description of the cholesterolins that much investigation is

still required to determine whether they are homologues or isomerides.

1. The various animal cholesterins (from biliary calculi, brains, &c.) have hitherto been considered to be one and the same substance, since preparations from many different sources have been found to possess the same melting-point, and also because of the homogeneity of the benzoic ether (Schulze a. Barbieri); but the point still requires further proof (Reinitzer, *M.* 9). It is not impossible that different cholesterins should occur in different animal organs, just as different varieties were found by Schulze and Barbieri in different parts of the yellow lupine (*cf.* Hesse, *A.* 192). For the probable relation of the cholesterins to the terpenes and camphors *v.* Walitzky (*B.* 9, 1310), Latschinoff (*B.* 12, 1518), Liebermann (*B.* 17, 871; 18, 1803), and Weyl (*Archiv f. Anat. u. Physiol.* 1, 182, *B.* 19, *Ref.* 618). The analogy of cholesterin to camphor is confirmed by the absence of any action when it is treated with hydroxylamine (Rayman, *Bl.* 47).

2. Iso-cholesterin is apparently a simple substance.

3. Para-cholesterin differs little from phyto-sterin, excepting in specific rotatory power, and requires to be further examined.

4. With regard to vegetable cholesterins, Hoppe-Seyler (*Handb. d. physiol. u. pathol. Chem. Analyse*, 4te Aufl. p. 110) surmised that cholesterin was probably a constant constituent of meristematic plant cells. Since they are so widely distributed among plants the cholesterins, according to Schulze and Barbieri, are to be looked upon as invariable constituents of the protoplasm. These last-named authors found cholesterins in very considerable quantity in the etiolated shoots, but only in very small quantity in the green plants of the yellow lupine, and hence they concluded that vegetable cholesterins, especially caulosterin, are decomposition products of albuminous compounds in the life process of the cells, a point already suggested by Hoppe-Seyler (*Handb.* 1, 81). Hesse considers that, because normal cholesterin possesses a stronger rotatory power than phytosterin, the former compound must be the next homologue to  $C_{26}H_{44}O$  i.e.  $C_{27}H_{46}O$ , the formula proposed by Walitzky, and also at one time by Berthelot (Gmelin, *Handb. d. Org. Chem.* 4, 2093), although the latter returned later on to the one usually accepted, viz.  $C_{26}H_{44}O$ ; Reinke and Rodewald, however, think this insufficient to overthrow the theory of the isomerism of the cholesterins. Cupreol, cinchol, and quebrachol (all of them  $C_{26}H_{44}O.H_2O$ ), and also Liebermann's cholestol (which is believed by Hesse to be nearly pure cinchol), all belong to this class of cholesterins. Reinitzer is of opinion that cynanocerin, cynan-chin, echicerin, and echitine (Hesse, *A.* 192, 182), aspidol (Dacomo, *Centralbl.* 87, 1357), ambrasin, castorin, &c., must also be included, and that the cholesterins will ultimately be found to be divisible into two homologous groups, dextro- and laevo-rotatory. For the latest discussion on this point, *v.* Reinitzer (*M.* 9). G. M.

**CHOLESTROPHANE** *v.* Di-methyl-Parabanic acid.

**CHOLIC ACID**  $C_{26}H_{46}O$ , i.e.  $C_{26}H_{44}(\text{CH.OH})(\text{CH}_2\text{OH})\text{CO}_2\text{H}$  (?). *Cholalic*

*acid.* [195°]. S. (of anhydrous crystals) 133 at 100°; -025 at 15°.

**Formation.**—By the hydrolytic action of alkalis on glycocholic and taurocholic acids, which occur in the bile (Demarçay, *A. Ch.* [2] 67, 173; Theyer a. Schlösser, *A.* 48, 77; 50, 235; Strecker, *A.* 65, 9; 67, 1; 70, 161, 166).

**Preparation.**—Glycocholic acid (50 grms.) is boiled for 16 hours with water (6 litres) and baryta (200 grms.). The liquid is filtered hot and, when cold, HCl added. A sandy pp. of cholic acid falls. Crystallises from alcohol. The yield is 80 p.c. (Hartmann, *J. pr.* [2] 19, 307; *cf.* Tappeiner, *A.* 194, 213).

**Properties.**—Crystallises from hot water in anhydrous microscopic crystals, from cold solutions, *e.g.* very dilute acetic acid, in trimetric tables (containing aq). The acid combines with methyl-, ethyl-, propyl-, and ethylene-alcohols and with mustard oils, but not with acetone. The hydrated and anhydrous acid and its various alcoholates all crystallise in the trimetric system, the axis-ratio *ac* remains constant whilst *bc* varies in the different alcoholates. Gives a blood-red colour with cane sugar and  $H_2SO_4$  (Pettenkofer's test, *v.* Bixs).

**Reactions.**—1. By gentle oxidation with acetic acid and  $CrO_3$  it yields dehydrocholic acid  $C_{24}H_{38}O_2$ , probably  $C_{24}H_{36}(\text{CO})(\text{CHO})\text{CO}_2\text{H}$ ; by more vigorous oxidation with  $K_2Cr_2O_7$  and  $H_2SO_4$ , billanic acid  $C_{24}H_{38}O_2$  is formed (but no cholanolic acid) (*cf.* Destrem, *C. R.* 87, 880; Clève, *C. R.* 91, 1073).—2. By putrefactive fermentation it is reduced to deoxycholic acid  $C_{26}H_{46}O$ . The latter acid probably accompanies cholic and choleic acids in saponified ox-gall.—3. Combines with iodine and HI or other metallic iodides to form unstable blue compounds  $(\text{A}^{\text{H}})\text{MI}$ , which greatly resemble iodide of starch in properties.— $(\text{A}^{\text{H}})\text{HI}$ , *zsq*: formed by adding iodine and HI to an alcoholic solution of cholic acid.— $(\text{A}^{\text{H}})\text{KI}$ , *zsq*: formed by adding iodine and KI to an alcoholic solution of cholic acid. Small bronzy needles, which suspended in water form an indigo-blue liquid. Readily decomposed into its constituents by heat, great dilution with water, alkalis, &c.— $(\text{A}^{\text{H}})\text{BaI}$ , *zsq*: like the preceding compounds (Mylus, *B.* 20, 683).

**Mono-acetyl derivative**  $C_{26}H_{44}(\text{OAc})O_2$ : formed by passing HCl gas through an acetic acid solution of cholic acid. Amorphous powder. V. c. sol. alcohol, ether, benzene, &c.

**Di-acetyl derivative**  $C_{26}H_{42}(\text{OAc})_2O_2$ : formed by allowing cholic acid to stand with cold acetic anhydride till it dissolves. White granular crystalline powder. V. sol. alcohol, ether, benzene, &c. insol. water. Bitter taste. Its Ba salt is insol. water (Latschinoff, *Bl.* [2] 33, 297; *B.* 18, 3039; 20, 1043; Mylius, *B.* 19, 869, 2000, 20, 1968). Schotten (*H.* 11, 268) denies the existence of acetyl derivatives of cholic acid.

**Amide**  $C_{26}H_{46}O_2.NH_2$ . Formed by heating the acid with alcoholic  $NH_3$  at 250°. Small crystals (containing 3aq). Sl. sol. water. The hydrated compound melts at [125°–130°]. The anhydrous compound melts slowly from [130°–140°], again solidifies at about 180° to a colourless crystalline mass, which again melts at [c. 223°]; if this crystalline mass is crystallised

from alcohol, nothing is obtained but the ordinary amide.

**Di-methyl-amide**  $C_{26}H_{50}O_4.NMe_2$ . [171°]. Formed by heating the acid with aqueous dimethylamine at 250°.

**Anhydrides**.—By heating cholic acid under various conditions mixtures of various anhydrides have been obtained, none of which have been isolated in a pure state (Mylius, *B.* 20, 1968).

**Ethyl ether**  $C_{26}H_{50}EtO_4$ . [147°].

**Preparation**.—Cholic acid (20 pts.) is dissolved in dilute (90 p.c.) alcohol (140 pts.) and the solution saturated, in the cold, with dry HCl. An equal volume of alcohol is at once added and every 100 c.c. of the liquid poured in a thin stream into a litre of water. After a few days, needles of the ether appear (Tappeiner; Hartmann).

**Dehydrocholic acid**  $C_{26}H_{48}O_4$ , probably  $C_{26}H_{48}(CO)(CHO).CO_2H$ . [232° uncor.] (L.). Formed by slowly adding a 10 p.c. solution of  $CrO_3$  (9 pts.) in acetic acid, to a 10 p.c. solution of cholic acid (10 pts.) in acetic acid. Anhydrous needles. By further oxidation with  $K_2Cr_2O_7$  and  $H_2SO_4$  it is converted into bilianic acid  $C_{26}H_{46}O_4$ , i.e.  $C_{26}H_{46}(CO)_2(CO_2H)_2$ . It does not give Pettenkofer's bile reaction.

**Tri-oxim**  $C_{26}H_{48}(NOH)_3O_4$ : formed by the action of a cold solution of hydroxylamine upon sodium dehydrocholate. Colourless microscopic tables. Sl. sol. hot alcohol, nearly insol. water and ether. Stable in alkaline solution, but resolved into its components by acids (Latschinoff, *B.* 18, 8045; Mylius, *B.* 19, 2005; 20, 1979).

**Phenyl-mercaptide**  $C_{27}H_{44}O_4(SC_6H_5)_2$ : [c. 220°]; colourless glistening needles; sl. sol. water. Formed by passing HCl through a cold solution of the acid in phenyl-mercaptan. The sodium salt forms fine needles, insol. water.

**Phenyl-mercaptide-phenyl-hydraside**  $C_{28}H_{46}(SC_6H_5)_2(N_2HCHO_2)_2CO_2H$ : separates in colourless needles on warming an acetic acid solution of the phenyl-mercaptide with phenylhydrazine (Mylius, *B.* 20, 1979).

**Desoxy-cholic acid** (probably identical with the so-called 'hydrated cholic acid' of Latschinoff)  $C_{25}H_{48}O_4$  (M.) or  $C_{25}H_{46}O_4$ , 1½aq (L.). [135°–140°] (L.); [160°–170°] (M.). Large dimetric crystals,  $\alpha:\alpha\alpha = 1:1:2.4828$  (L.). White needles, v. sol. alcohol, sl. sol. acetic acid (M.). Occurs, together with cholic and choleic acids, in saponified ox-gall (L.). Formed by putrefactive fermentation of cholic acid (M.). According to L. it is formed in small quantity by boiling cholic acid with acetic acid, but M. was unable to effect this conversion. By gentle oxidation, with  $CrO_3$  and acetic acid it is converted into dehydrocholic acid; by more vigorous oxidation with  $K_2Cr_2O_7$  and  $H_2SO_4$  into cholanolic acid (L.) (Latschinoff, *B.* 18, 8041; 20, 1043; Mylius, *B.* 19, 878; 20, 1968).

The observations marked (L.) refer to Latschinoff's hydrated choleic acid, those marked (M.) relate to the desoxycholic acid of Mylius.

**CHOLINE v. NEURINE.**

**CHOLEIDANIC ACID**  $C_{26}H_{50}O_4$ , i.e.  $C_{26}H_{50}O(CO_2H)_3$  (?). *Cholecamphoric acid*. S. 015 at 18°; 18 at 100°. [ $\alpha$ ]<sub>D</sub> 57° 56'. Formed, together with pseudo-choleidanic acid, by boil-

ing cholanolic acid (1 g.) with  $HNO_3$  (30 c.c. of S.G. 1.28) for several hours. Formed also by the action of  $HNO_3$  on bile (Thayer a. Schlösser, *A.* 50, 243) or cholic acid (Reichenbacher, *A.* 57, 145; Tappeiner, *A.* 194, 239; Clève, *Bl.* [2] 88, 135).

**Salts**.— $A^+Ag$ , 4aq: gelatinous pp.— $A^+Pb$ : amorphous pp.— $A^+Ba$ , 20aq: thick prismatic crystals, S. (at 18°) about 20 (Latschinoff, *B.* 13, 1052; 19, 1521).

**Pseudo-choleidanic acid**  $C_{26}H_{50}O_4$  (?). Formed, together with choleidanic acid, by boiling cholanolic acid (1 g.) with  $HNO_3$  (30 c.c. of S.G. 1.28) for several hours. Microscopic needles.

**Salts**.— $A^+H$ ,  $Ba$ , 20aq: flat needles.— $A^+Ag$ : amorphous pp.

**Ethyl derivative**  $C_{26}H_{50}(C_2H_5)_2O_4$ : [247°]. Obtained by the action of  $EtI$  upon the lead salt. Needles. V. sol. alcohol, less in ether.— $C_{26}H_{50}EtO_4.Ba$ , 2aq: prisms.

**Methyl derivative**  $C_{26}H_{50}(CH_3)_2O_4$ : [194°–196°]; needles.

**Neutral methyl ether**  $C_{26}H_{50}(CH_3)_2O_4$ : [128°]. Obtained by the action of ethyl iodide upon the silver salt. Flat needles (from alcohol) (Latschinoff, *B.* 19, 1521; cf. Clève, *Bl.* [2] 88, 135).

**CHONDRIN v. PROTEIDS, appendix C.**

**CHROMATES, Salts of Chromic Acid; v. CHROMIUM, ACIDS OF, p. 154.**

**CHROMIUM** Cr. At. w. 52.45. Mol. w. unknown. [Above M. P. of Pt which is about 2500°] (Deville, *A.Ch.* [3] 46, 182). S.G. 6.5–6.8 (Wöhler, *A.* 11, 230; Loughlin, *Am. S.* [2] 45, 131; Rammelsberg, *Handbuch d. kristallog. u. physikal. Chemie*, part 1 [1881]). S.H. (22°–50°) .0998 (uncertain) (Kopp, *T.* 155, 71). S.V.S. about 7.8.

**Occurrence**.—Never free: chiefly as oxide in combination with FeO as *chrome-ironstone*,  $FeO.Cr_2O_3$ , with  $Cr_2O_3$  more or less replaced by  $Fe_2O_3$  and  $Al_2O_3$ , and FeO by MgO. Also as basic chromate of lead, as chromic oxide, &c. The ores of Cr are not very widely distributed. Chromium was discovered by Vauquelin in 1797; the name was given ( $\chi\rho\omicron\mu\alpha$ ) because of the number of compounds of different colours obtained from the metal.

**Preparation**.—Chrome ironstone is separated from gangue, finely powdered, washed, mixed with CaO and KHO, dried at 150°, and heated to bright redness in contact with air, the mass being constantly stirred; after cooling, the  $K_2CrO_4$  formed is dissolved out in a little warm  $H_2O$ , enough conc.  $H_2SO_4$  to convert all the  $K_2CrO_4$  into  $K_2Cr_2O_7$  is added, and the  $K_2Cr_2O_7$ , which separates is re-crystallised from hot  $H_2O$ . The  $K_2Cr_2O_7$  is heated with S, or starch, or  $NH_4Cl$ , and the product washed with  $H_2O$ , in which the  $Cr_2O_3$  formed remains undissolved (v. **CHROMIO OXIDE, p. 164**).  $Cr_2O_3$  is then mixed with rather less charcoal than is theoretically

required for complete reduction, and heated to a very high temperature in a lime crucible.  $\text{Cr}_2\text{O}_3$  is mixed with charcoal, and heated in  $\text{Cl}_2$  whereby  $\text{CrCl}_3$  (aq.) is obtained; the  $\text{CrCl}_3$  is then heated to bright redness, and  $\text{H}$  carrying with it  $\text{Na}$  vapour is passed over it; monometric crystals of  $\text{Cr}$  are thus obtained (Fremy, *C. R.* 44, 632). Wöhler (*A.* 111, 230) mixes 1 part violet  $\text{CrCl}_3$  with 2 parts of a fused and powdered mixture of 7 parts  $\text{NaCl}$  and 9 parts  $\text{KCl}$ , presses the mixture firmly into a crucible, and places 2 parts granulated  $\text{Zn}$  over it, and more  $\text{NaCl}$  and  $\text{KCl}$  over this again; he gradually heats until the mass is melted. As soon as the  $\text{Zn}$  boils, and the flame of burning  $\text{Zn}$  is seen on removing the crucible, the temperature is decreased, and the mass is kept just melted for 10 minutes. The whole is then allowed to cool, the crucible being shaken once or twice; the crucible is broken, the zinc regulus dissolved in dilute  $\text{HNO}_3$ , the metallic  $\text{Cr}$  then boiled once with  $\text{HNO}_3$ , washed, and dried. Zettnow prepares  $\text{CrCl}_3$  solution by reducing  $\text{K}_2\text{Cr}_2\text{O}_7$  in  $\text{HCl}$  aq. by  $\text{C}_2\text{H}_5\text{O}$ , adds  $\text{KCl}$ , evaporates to dryness, and reduces by  $\text{Zn}$  as already described (*P.* 143, 477). According to Bunsen (*P.* 91, 619)  $\text{Cr}$  may be obtained in lustrous plates by electrolysis an acid solution of  $\text{CrCl}_3$  containing  $\text{CrCl}_3$ . Vincent (*P. M.* [4] 24, 328) and Roussin (*J. Ph.* [4] 3, 413) form an amalgam of  $\text{Cr}$ , by acting on solution of a chromic salt by  $\text{Na}$  amalgam, and heat this in  $\text{H}$  or vapour of rock-oil.

**Properties.**—Descriptions of properties of  $\text{Cr}$  vary considerably. The metal obtained by reducing  $\text{CrCl}_3$  by  $\text{Na}$  vapour, or by reducing  $\text{Cr}_2\text{O}_3$  by  $\text{C}$ , is described (Fremy, *C. R.* 44, 632) as unchanged by heating in air, in *aqua regia* or  $\text{HFAg}$ , or by fusing with  $\text{KOH}$  or  $\text{KNO}_3$ . The metal obtained by electrolysis (Bunsen, *P.* 91, 619), or by reducing  $\text{CrCl}_3$  by  $\text{Zn}$  (Wöhler, *A.* 111, 230), is oxidised by molten  $\text{KNO}_3$  or  $\text{KClO}_4$ , and is dissolved in hot dilute  $\text{HCl}$  aq. or  $\text{H}_2\text{SO}_4$  aq. Berzelius (*A.* 49, 247) supposed that  $\text{Cr}$  existed in two distinct forms. The metal insoluble in *aqua regia* probably contained  $\text{Si}$  derived from the vessels. According to Bunsen and Wöhler,  $\text{Cr}$  is a greyish-white powder, consisting of small, lustrous, very hard, brittle, rhombohedral crystals (dimetric octahedra, Bolley, *C. J.* 13, 333); only superficially oxidised, unless in very fine powder, by heating in air; slowly oxidised by heating to redness in steam; burns brightly when heated in an alcohol flame fed with  $\text{O}$ ; oxidised by molten  $\text{KClO}_4$  or  $\text{KNO}_3$ , but not by molten  $\text{Na}_2\text{CO}_3$ ; dilute  $\text{HCl}$  aq. or hot dilute  $\text{H}_2\text{SO}_4$  aq. dissolves it readily with evolution of  $\text{H}$ ; scarcely acted on by hot conc.  $\text{HNO}_3$  aq.; burns in  $\text{Cl}_2$  gas forming violet  $\text{CrCl}_3$ .  $\text{Cr}$  is less fusible than  $\text{Pt}$  (Deville, *A. Ch.* [3] 46, 182). It is not magnetic (Wöhler, *A.* 111, 230); slightly magnetic (Faraday).

The atomic weight of  $\text{Cr}$  has been determined (1) by analysing and determining V.D. of  $\text{CrOCl}_2$  and  $\text{CrCl}_3$ ; (2) by measuring the S.H. of  $\text{Cr}$ ; (3) by analyses, and comparison with other analogous compounds, of  $\text{CrCl}_3$  (Péligot, *A. Ch.* [3] 12, 530);  $\text{Ag}_2\text{CrO}_4$  and  $\text{Ag}_2\text{Cr}_2\text{O}_7$  (Berlin, *A.* 56, 207);  $\text{Cr}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 24\text{H}_2\text{O}$  (Moberg, *J. pr.* 43, 114);  $\text{CrCl}_3$  (Siewert, *J.* 1861. 241); by synthesis of  $\text{BaCrO}_4$  from  $\text{BaCl}_2$  (Wildenstein, *J. pr.* 59, 27); by oxidising  $\text{FeCl}_3$  aq. by  $\text{K}_2\text{Cr}_2\text{O}_7$ , and by  $\text{KClO}_4$ ,

and by oxidising  $\text{As}_2\text{O}_3$  aq. by  $\text{K}_2\text{Cr}_2\text{O}_7$  (Kessler, *P.* 95, 210); (4) by comparing chromates with isomorphous manganates and tellurates. The atom of  $\text{Cr}$  is trivalent in the gaseous molecule  $\text{CrCl}_3$  (Scott, *Pr. E.* 14, 410) (v. CHROMIUM HEXAFLUORIDE, under CHROMIUM FLUORIDES OF, p. 162).

Chromium is both metallic and non-metallic;  $\text{Cr}$  replaces the  $\text{H}$  of most acids forming two series of salts, the simplest formulae for which are  $\text{CrX}_2$  and  $\text{CrX}_3$ , respectively, where  $\text{X} = \text{Cl}_2$  &c.,  $\text{NO}$ , &c.,  $\frac{\text{SO}_4}{2}$  &c.,  $\frac{\text{PO}_4}{3}$  &c.; the

chromous salts,  $\text{CrX}_2$ , are very unstable, and are easily oxidised to chromic salts,  $\text{CrX}_3$ . Many basic chromic salts are known. The oxide  $\text{Cr}_2\text{O}_3$  is basic towards acids, and at the same time exhibits feebly acidic properties;  $\text{CrO}$  seems to be a neutral oxide and not to form salts either by the action of acids or alkalis;  $\text{CrO}$  is distinctly an anhydride.  $\text{CrO}_3$  aq. behaves as a dibasic acid, forming a series of salts  $\text{M}_2\text{CrO}_7$ , the acid  $\text{H}_2\text{CrO}_4$  has also been obtained. Although no salts of the form  $\text{MHCrO}_4$  are known as definite solids, yet the thermal reactions of  $\text{CrO}_3$  aq. point to the formation of these salts; thus (*Th.* 1, 254)

$n$  [ $\text{CrO}_3$  aq.,  $n$   $\text{NaOH}$  aq.]

1	13,134
2	24,720
4	25,164.

By the action of acids on  $\text{M}_2\text{CrO}_7$ , dichromates,  $\text{M}_2\text{Cr}_2\text{O}_7$ , are formed; a few tri- and tetra-chromates,  $\text{M}_3\text{Cr}_3\text{O}_{10}$  and  $\text{M}_4\text{Cr}_4\text{O}_{13}$ , are known.  $\text{CrO}_3$  also reacts with strong acids to form chromic salts and  $\text{O}$ ; it combines directly with a few anhydrides, e.g. with  $\text{SO}_3$ . Chromic oxide,  $\text{Cr}_2\text{O}_3$ , reacts towards acids as a salt-forming oxide, but at the same time it combines with some of the more positive metallic oxides, e.g. with  $\text{CaO}$ ,  $\text{MnO}$ ,  $\text{ZnO}$ . Several hydroxides of  $\text{Cr}$ , or perhaps rather hydrated oxides, are known, derived from the oxide  $\text{Cr}_2\text{O}_3$ , and the lower oxide  $\text{CrO}$  which has not itself been obtained free from  $\text{Cr}_2\text{O}_3$ ; these hydrates are salt-forming in their reactions with acids. The pps. produced by adding  $\text{KOH}$  aq. or  $\text{NaOH}$  aq. to solutions of chromic salts always contain potash or soda which cannot be removed by washing with hot water.  $\text{Cr}_2\text{S}_3$  exhibits slight salt-forming properties in its reactions towards sulphides of more positive metals; no hydrosulphide of  $\text{Cr}$  is known. Chromium is closely related to  $\text{Mo}$ ,  $\text{W}$ , and  $\text{U}$ ; less closely to  $\text{S}$ ,  $\text{Se}$ , and  $\text{Te}$ ; it also shows distinct relations to  $\text{Al}$ ,  $\text{Mn}$ , and  $\text{Fe}$  (v. CHROMITES; CHROMIUM GROUP OF ELEMENTS; also CHROMIUM, SALTS OF; CHROMATES; and the arts. on HYDROXIDES, OXIDES, CHLORIDES, &c. OF CHROMIUM).

**Reactions.**—1. Decomposes steam at bright red heat.—2. Dissolves in hydrochloric and sulphuric acids, forming salts and  $\text{H}$ .—3. Oxidised by molten potassium nitrate or chlorate.—4. Burns when heated in chlorine, forming  $\text{CrCl}_3$ .—5. Is oxidised by strongly heating in oxygen.—6. Forms  $\text{CrN}$  by heating in nitrogen, and  $\text{Cr}_3\text{S}_8$  by heating with sulphur.

**Combinations.**—Most of the compounds of  $\text{Cr}$  are obtained directly or indirectly from the oxides. The metal combines directly with  $\text{Cl}$ ,  $\text{N}$ ,  $\text{O}$ , and  $\text{S}$ . Compounds of  $\text{Cr}$  with each of the non-metals, except  $\text{H}$ ,  $\text{B}$ ,  $\text{Si}$ , and  $\text{Te}$ , are known; alloys with  $\text{Al}$ ,  $\text{Fe}$ , and  $\text{Hg}$ , have been prepared

(v. the various binary compounds of Cr, also CHROMIUM, ALLOYS or).

**Estimation.**—Chromium may be estimated in the form of oxide  $\text{Cr}_2\text{O}_3$ , after ppn. by  $\text{NH}_4\text{Aq}$  from a warm solution. Chromates are usually estimated as  $\text{BaCrO}_4$ , or they may be ppd. by  $\text{HgNO}_3\text{Aq}$ , and the  $\text{Hg}_2\text{CrO}_4$  heated until only  $\text{Cr}_2\text{O}_3$  remains; or the chromate may be reduced, by alcohol, to a chromic salt, and the Cr determined by ppn. with  $\text{NH}_4\text{Aq}$  &c. Cr may be separated from many heavy metals by ppg. these metals as sulphides, by  $\text{H}_2\text{S}$ ; Ba and Sr are best separated by ppn. with  $\text{H}_2\text{SO}_4\text{Aq}$ ; separation from Ca, Mg, and Fe, is effected by ppg.  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  by  $\text{NH}_4\text{Aq}$ , collecting, drying, and fusing with  $\text{KNO}_3$  and  $\text{K}_2\text{CO}_3$  until all the Cr exists as  $\text{K}_2\text{CrO}_4$ , dissolving in water and ppg. as  $\text{Hg}_2\text{CrO}_4$  or  $\text{BaCrO}_4$ . If alumina is present, it is ppd. from the solution containing  $\text{K}_2\text{CrO}_4$  by digesting with ammonium carbonate.  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  is ppd. by digesting solutions of chromic salts with excess of  $\text{BaCO}_3$ ; under the same conditions salts of Ni, Co, Mn, and Zn, are not ppd.

Chromium, acids of, and their salts (comp. arts. ACIDS; ACIDS, BASICITY or; HYDROXIDES). Chromic acid  $\text{H}_2\text{CrO}_4$  is said to have been obtained in definite form, by the action of  $\text{H}_2\text{O}$  on the anhydride  $\text{CrO}_3$  (v. *infra*, CHROMIC ACID). This acid forms a series of chromates,  $\text{M}_2\text{CrO}_4$ , isomorphous with  $\text{M}_2\text{SO}_4$ .  $\text{H}_2\text{CrO}_4\text{Aq}$  reacts as a dibasic acid (v. *infra*, CHROMIC ACID); no salts of the form  $\text{MHCrO}_4$ , but only the salts  $\text{M}_2\text{CrO}_4$ , have been obtained by neutralising the acid by alkalis; when acids react with chromates of monovalent metals  $\text{M}_2\text{CrO}_4$ , two formula-weights of the chromate usually react with one formula-weight of a dibasic acid (e.g.  $\text{H}_2\text{SO}_4$ ), half of M is removed, and a *chromate*,  $\text{M}_2\text{CrO}_4$ ,—similar to the disulphates  $\text{M}_2\text{S}_2\text{O}_8$ ,—is produced. Several *trichromates*  $\text{M}_2\text{Cr}_3\text{O}_{10}$ , and *tetrachromates*  $\text{M}_2\text{Cr}_4\text{O}_{14}$ , are also known; these salts are probably best regarded as derived from  $\text{M}_2\text{Cr}_2\text{O}_7$  and  $\text{M}_2\text{CrO}_4$ , and from  $2\text{M}_2\text{Cr}_2\text{O}_7$ , respectively, by the removal of half the total M and condensation of the residues. The following formulæ express this view of the constitution of the di-, tri-, and tetra-, chromates:

- (1) *Chromic acid*,  $\text{CrO}_3(\text{OH})_2$ ;
- (2) *Chromates*,  $\text{CrO}_4(\text{OM})_2$ ;
- (3) *Dichromates*,  $\text{OM} \cdot \text{CrO}_2 \cdot \text{O} \cdot \text{CrO}_2 \cdot \text{OM}$ ;
- (4) *Trichromates*,  $\text{OM} \cdot \text{CrO}_2 \cdot \text{O} \cdot \text{CrO}_2 \cdot \text{O} \cdot \text{CrO}_2 \cdot \text{OM}$ ;
- (5) *Tetrachromates*,

These various series of salts may also be regarded as direct compounds of metallic oxide with  $\text{CrO}_3$  ( $\text{M}_2\text{O} \cdot \text{CrO}_3$ ;  $\text{M}_2\text{O} \cdot 2\text{CrO}_3$ ;  $\text{M}_2\text{O} \cdot 3\text{CrO}_3$ ;  $\text{M}_2\text{O} \cdot 4\text{CrO}_3$ ). Besides these salts, several basic chromates are known (v. *infra*). Chromic acid,  $\text{H}_2\text{CrO}_4$ , being dibasic, and forming  $\text{M}_2\text{CrO}_4$ , analogous with  $\text{M}_2\text{SO}_4$ , is probably a dihydroxyl acid,  $\text{CrO}_3(\text{OH})_2$ . If this is so we should expect that each OH would be replaceable by Cl; the first compound thus produced,  $\text{CrO}_2\text{Cl} \cdot \text{OH}$ , ought to be a monobasic acid (analogous with  $\text{SO}_2\text{Cl} \cdot \text{OH}$ ); this compound is not itself known, but several salts derived from it have been prepared, e.g.  $\text{CrO}_2\text{Cl} \cdot \text{ClOK}$  (v. *infra*, under Chromates). *Fluo-, bromo-, and iodo-, chromates*,  $\text{CrO}_4 \cdot \text{X} \cdot \text{OM}$  (where  $\text{X} = \text{F}$ , &c., and M = alkali metal), are also known.

Salts of the hypothetical *amido-chromic acid* ( $\text{CrO}_2 \cdot \text{NH}_2 \cdot \text{OM}$ ) are known; and it is probable that *nitro-derivatives* of  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{K}_2\text{CrO}_4$ , respectively, have been obtained, viz.  $\text{Cr}_2\text{O}_7 \cdot \text{NO}_2 \cdot \text{OK}$  and  $\text{Cr}_2\text{O}_4 \cdot \text{NO}_2 \cdot \text{OK}$  (v. *Potassium dichromate*, under *Dichromates*).  $\text{Cr}_2\text{O}_3$  reacts towards acids as a salt-forming or positive oxide; no acid corresponding to this oxide is known; the oxide is itself insoluble in  $\text{H}_2\text{O}$ . Salts  $\text{MO} \cdot \text{Cr}_2\text{O}_3$ , where M = Zn, Mn, Fe, &c., have, however, been prepared, by fusing MO and  $\text{Cr}_2\text{O}_3$  with  $\text{B}_2\text{O}_3$  &c.; these may be regarded as derivatives of the hypothetical chromous acid  $\text{H}_2\text{CrO}_2$  (v. Chromites, p. 158). The sulphide  $\text{Cr}_2\text{S}_3$ , corresponding to  $\text{Cr}_2\text{O}_3$ , also reacts as a feebly salt-forming compound towards more positive sulphides (v. CHROMIUM, THIOACID or, p. 168).

CHROMIC ACID  $\text{H}_2\text{CrO}_4$ . Said to be obtained as small red crystals by adding a little  $\text{H}_2\text{O}$  to excess of pure  $\text{CrO}_3$ , keeping the solution for some hours at  $90^\circ$ , decanting and cooling to  $0^\circ$  (Moissan, *A. Ch.* [6] 5, 568). But Miss Field has shown that the crystals thus obtained are  $\text{CrO}_3$ ; the solution, however, probably contains  $\text{H}_2\text{CrO}_4$  and  $\text{H}_2\text{Cr}_2\text{O}_7$  (*C. J.* 61, 405 [1892]). The thermal values of the reaction between  $\text{NaOH}\text{Aq}$  and  $\text{H}_2\text{CrO}_4\text{Aq}$  show that this acid is dibasic; salts of the form  $\text{MHCrO}_4$  appear not to exist as solids; if enough alkali is added to saturate half the  $\text{H}_2\text{CrO}_4$  in solution, and the liquid is evaporated, the salt  $\text{M}_2\text{CrO}_4$  is obtained—probably  $2\text{MHCrO}_4$  is formed and decomposed to  $\text{M}_2\text{CrO}_4$  and  $\text{H}_2\text{O}$ . If  $\text{H}_2\text{CrO}_4\text{Aq}$  is added to solution of  $\text{M}_2\text{CrO}_4$ ,  $\text{M}_2\text{CrO}_4$  is obtained on evaporation. The thermal data (*Th.* 1, 255) show (1) the dibasicity of the acid, and (2) the action of excess of acid on the normal salts: the corresponding data for  $\text{H}_2\text{SO}_4\text{Aq}$  are given; addition of  $\text{H}_2\text{SO}_4\text{Aq}$  to  $\text{K}_2\text{SO}_4\text{Aq}$  produces  $\text{KHSO}_4\text{Aq}$  :—

$n$ ( $n\text{NaOH}\text{Aq}$ , $\text{CrO}^*\text{Aq}$ )	$m$ ( $m\text{CrO}^*\text{Aq}$ , $2\text{NaOH}\text{Aq}$ )
1 13,134	$\frac{1}{2}$ 12,592
2 24,720	1 24,720
4 25,164	2 26,268
$n$ ( $n\text{NaOH}\text{Aq}$ , $\text{SO}^*\text{Aq}$ )	$m$ ( $m\text{SO}^*\text{Aq}$ , $2\text{NaOH}\text{Aq}$ )
1 14,754	$\frac{1}{2}$ 15,689
2 31,378	1 31,378
4 31,368	2 29,508

Chromates. (*Di-, tri-, tetra-, chromates*).  $\text{M}_2\text{CrO}_4$  or  $\text{M}^*\text{CrO}_4$ ; also basic and double salts. Chromates are mostly yellow or red; the salts of the alkali metals, and of Ca, Mg, and Sr, are e. sol. water, the others are generally insol. or sl. sol. They are formed by the action of bases on  $\text{H}_2\text{CrO}_4\text{Aq}$ ; by fusing  $\text{CrO}_3$  with alkali in presence of air; or by double decomposition from the alkali salts. Neutral  $\text{M}_2\text{CrO}_4\text{Aq}$  (M = alkali metal) goes red on addition of a mineral acid from formation of  $\text{M}_2\text{Cr}_2\text{O}_7\text{Aq}$ , on adding alkali the yellow colour returns. Chromates are easily reduced to  $\text{Cr}_2\text{O}_3$  or salts of this oxide; e.g. boiling  $\text{HClAq}$  produces  $\text{CrCl}_3\text{Aq}$ , and chloride of the metal,  $\text{H}_2\text{SO}_4\text{Aq}$  produces  $\text{Cr}_2\text{SO}_4\text{Aq}$ . Chromates of the less positive metals give  $\text{Cr}_2\text{O}_3$  when strongly heated;  $\text{M}_2\text{CrO}_4$  (M = alkali metal) give  $\text{Cr}_2\text{O}_3$ , O, and  $\text{M}_2\text{CrO}_4$ . Insoluble chromates yield alkali chromates by fusion with KOH or NaOH. Heated with NaCl and conc.  $\text{H}_2\text{SO}_4$ , chromates give  $\text{CrO}_2\text{Cl}_2$ . Solutions of chromates have a metallic taste, and are poisonous.

**Aluminium chromate.**—The basic salt  $\text{Al}_2(\text{CrO}_4)_3 \cdot 2\text{Al}_2\text{O}_3 \cdot 21\text{H}_2\text{O}$  ( $= \text{Al}_2\text{O}_3 \cdot \text{CrO}_3 \cdot 7\text{H}_2\text{O}$ ) is a flocculent yellow pp. obtained by adding  $\text{K}_2\text{CrO}_4$  to alum solution, or by evaporating  $\text{Al}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  in  $\text{CrO}_3$  (Fairrie, *C. J.* 4, 300; Mans, *P.* 11, 81; Elliot a. Storer, *P. Am. A.* 5, 192).

**Ammonium chromate.**— $(\text{NH}_4)_2\text{CrO}_4$ . Citron-yellow needles; e. sol. water; gives off  $\text{NH}_3$  in air; on heating leaves  $\text{Cr}_2\text{O}_3$ . Obtained by slowly adding  $\text{CrO}_3$  to excess of  $\text{NH}_4\text{Aq}$ , and evaporating below  $60^\circ$ ; also by  $\text{BaCrO}_4 + (\text{NH}_4)_2\text{SO}_4$  and by  $\text{CrO}_3$  and  $\text{NH}_4\text{Aq}$  (Daryl, *A.* 65, 2041) (v. Di-, Tri-, and Hexa-chromates).

**Barium chromate**  $\text{BaCrO}_4$ . Yellow, crystalline powder; obtained by  $\text{K}_2\text{CrO}_4$  and  $\text{BaCl}_2$  Aq; S.G. 4.9; also by fusing 1 pt.  $\text{K}_2\text{CrO}_4$  with 1 pt.  $\text{Na}_2\text{CrO}_4$  and 2 pts.  $\text{BaCl}_2$ , and cooling slowly; S.G. 4.6 (Bourgeois, *Bl.* [2] 31, 243). Insol.  $\text{H}_2\text{O}$ ; sol.  $\text{HClAq}$ , or  $\text{HNO}_3$  Aq, and reppd. by  $\text{NH}_4\text{Aq}$ . Decomposed by alkali carbonates and sulphates (Rose, *P.* 95, 426) (v. Dichromates).

**Beryllium chromate.**—Basic salt  $\text{BeCrO}_4 \cdot 13\text{BeO} \cdot 23\text{H}_2\text{O}$ ; yellow pp., insol.  $\text{H}_2\text{O}$  (Creuzburg, *D. P. J.* 163, 449).

**Bismuth chromates** (Löwe, *J. pr.* 67, 288 a. 463; Pearson, *P. M.* [4] 11, 204; Pattison Muir, *C. J.* [2] 15, 12; [2] 16, 24 a. 645). Normal chromate,  $\text{Bi}_2(\text{CrO}_4)_3$ , has not been prepared. The following basic salts are known:— $2(\text{Bi}_2\text{CrO}_4) \cdot 7\text{Bi}_2\text{O}_3$ , by ppg.  $\text{Bi}_2\text{NO}_3$  in small excess of  $\text{HNO}_3$  Aq by  $\text{K}_2\text{CrO}_4$  Aq;  $2(\text{Bi}_2\text{CrO}_4) \cdot \text{Bi}_2\text{O}_3$ , by ppg. a more acid solution of  $\text{Bi}_2\text{NO}_3$  in  $\text{HNO}_3$  Aq by  $\text{K}_2\text{CrO}_4$  Aq;  $(\text{Bi}_2\text{CrO}_4) \cdot 2\text{Bi}_2\text{O}_3$ , by boiling the preceding salt with dilute  $\text{HNO}_3$  Aq or with alkali;  $3(\text{Bi}_2\text{CrO}_4) \cdot \text{Bi}_2\text{O}_3$ , by prolonged heating  $2(\text{Bi}_2\text{CrO}_4) \cdot \text{Bi}_2\text{O}_3$  with dilute  $\text{HNO}_3$  Aq;  $7(\text{Bi}_2\text{CrO}_4) \cdot 2\text{Bi}_2\text{O}_3$ , by treating  $(\text{Bi}_2\text{CrO}_4) \cdot 2\text{Bi}_2\text{O}_3$  first with conc., then with dilute,  $\text{HNO}_3$  Aq. These salts are all yellow to red, heavy, crystalline powders; insol. water, and slowly decomposed by hot acids (v. also Dichromates).

**Cadmium chromate.**—Basic salt  $\text{CdCrO}_4 \cdot \text{CdO} \cdot \text{H}_2\text{O}$ ; by reaction of  $\text{CdSO}_4$  Aq with large excess of  $\text{K}_2\text{CrO}_4$  Aq (Freese, *B.* 2, 476; Sarzeau a. Malaguti, *A. Ch.* [3] 9, 431).

**Calcium chromate**  $\text{CaCrO}_4 \cdot 2\text{H}_2\text{O}$ ; by dissolving  $\text{CaCO}_3$  in  $\text{CrO}_3$  Aq and evaporating. Yellow prisms; S. ( $14^\circ$ ) 41; insoluble in alcohol; loses its  $\text{H}_2\text{O}$  at  $200^\circ$  (Siewert, *Z. f. d. g. Naturwiss.* 19, 11) (v. Dichromates).

**Cerium chromate**  $\text{Ce}(\text{CrO}_4)_2$ ; yellow powder, by dissolving  $\text{Ce}(\text{CrO}_4)_2$  in  $\text{CrO}_3$  Aq and evaporating (Berlinger, *A.* 42, 143).

**Chromium chromate**  $(\text{Cr}_2\text{CrO}_4) \cdot 2\text{Cr}_2\text{O}_3$ . This name and composition is sometimes assigned to  $\text{CrO}_2$  (v. CHROMIUM DIOXIDE under CHROMIUM, OXIDES OF, p. 164).

**Cobalt chromates.**—Basic cobaltous salt  $\text{CoCrO}_4 \cdot \text{CoO} \cdot \text{H}_2\text{O}$  (Freese, *B.* 2, 476);  $\text{CoCrO}_4 \cdot 2\text{CoO} \cdot \text{H}_2\text{O}$  (Sarzeau a. Malaguti, *A. Ch.* [3] 9, 431). Clear red-brown pp. by  $\text{Co}_2\text{SO}_4$  Aq +  $\text{K}_2\text{CrO}_4$  Aq. Cobaltic chromate  $\text{Co}_2(\text{CrO}_4)_3$  is known in combination with  $\text{NH}_3$  and  $\text{NH}_4\text{Cl}$ ; the salts  $(\text{Co}_2\text{CrO}_4) \cdot 10\text{NH}_3$ ,  $(\text{Co}_2\text{CrO}_4) \cdot 12\text{NH}_3 \cdot 5\text{H}_2\text{O}$ , and  $(\text{Co}_2\text{CrO}_4) \cdot 2\text{NH}_3 \cdot 2\text{NH}_4\text{Cl}$ , are described by Braun (*A.* 125, 153 a. 197), Gibbs a. Genth (*A.* 104, 150 a. 295), and Gibbs (*B.* 4, 790) (v. also CHROMIUM, AMMONIO-SALTS OF).

**Copper chromates.**—Basic salts:

$\text{CuCrO}_4 \cdot 2\text{CuO} \cdot 2\text{H}_2\text{O}$ , yellowish-brown pp., by  $\text{K}_2\text{CrO}_4$  Aq +  $\text{CuSO}_4$  Aq, and by  $\text{CuSO}_4$  Aq +  $\text{K}_2\text{Cr}_2\text{O}_7$  Aq, and adding enough  $\text{KOH}$  to produce  $\text{K}_2\text{CrO}_4$  Aq (Freese, *P.* 140, 87; Rosenfeld, *B.* 13, 1469). Loses its  $\text{H}_2\text{O}$  at  $260^\circ$  and takes it up again in moist air. Two salts,  $2(\text{CuCrO}_4) \cdot 5\text{CuO} \cdot 5\text{H}_2\text{O}$ , and  $\text{CuCrO}_4 \cdot 6\text{CuO} \cdot 5\text{H}_2\text{O}$ , are described by Rosenfeld (*l.c.*); obtained by adding  $\text{CuSO}_4$  to  $\text{K}_2\text{Cr}_2\text{O}_7$  Aq with excess of  $\text{KOH}$  Aq. The salt  $\text{CuCrO}_4 \cdot 2\text{CuO} \cdot 2\text{H}_2\text{O}$  dissolves in  $\text{NH}_4\text{Aq}$  at  $0^\circ$ ; dark-green crystals of  $2(\text{CuCrO}_4) \cdot \text{CuO} \cdot 10\text{NH}_3 \cdot 2\text{H}_2\text{O}$  separate (Sarzeau a. Malaguti, *A. Ch.* [3] 9, 431; Viehhaus, *J. pr.* 88, 431; Slater, *J. pr.* 60, 247) (v. also Potassium chromate).

**Iron chromate.**—Basic ferric salt  $(\text{Fe}_2\text{CrO}_4) \cdot 2\text{Fe}_2\text{O}_3$ ; brown pp. by  $\text{K}_2\text{CrO}_4$  Aq acting on iron-alum solution; decomposed by  $\text{H}_2\text{O}$  to  $\text{Fe}_2\text{O}_3$  and  $\text{CrO}_3$  Aq. An acid salt,  $\text{Fe}_2(\text{CrO}_4)_3$ , is said to be formed by digesting  $\text{CrO}_3$  Aq with  $\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$ , and evaporating (Kletzensky, *D. P. J.* 207, 83; Elliot a. Storer, *P. Am. A.* 5, 192).

**Lead chromate**  $\text{PbCrO}_4$ . Occurs native as red-lead ore, in yellow, translucent, monoclinic prisms, S.G. 5.2 to 6.1. Obtained as yellow pp. by  $\text{K}_2\text{CrO}_4$  Aq or  $\text{K}_2\text{Cr}_2\text{O}_7$  Aq acting on neutral solution of a Pb salt; also in crystals by strongly heating  $\text{K}_2\text{CrO}_4$  with  $\text{PbCl}_2$ , S.G. of crystals 6.12 (Manross, *A.* 82, 348; Drevermann, *A.* 87, 120). S.H. '09 (Kopp, *A. Suppl.* 3, 1). Insol. in  $\text{H}_2\text{O}$ , sol. in  $\text{HNO}_3$  Aq or  $\text{KOH}$  Aq; melts without change, but at higher temperature gives  $\text{O}$ ,  $\text{Cr}_2\text{O}_3$ , and a basic salt ( $\text{PbCrO}_4 \cdot \text{PbO}$ ). Acts as an oxidiser, hence used in organic analysis (v. Vohl, *A.* 106, 127).

Basic salt  $\text{PbCrO}_4 \cdot \text{PbO}$ ; red crystals, obtained by throwing  $\text{PbCrO}_4$  in small quantities into molten  $\text{KNO}_3$ , cooling somewhat, pouring off still liquid part, and quickly washing residue with  $\text{H}_2\text{O}$ ; also by digesting  $\text{PbCrO}_4$  with cold  $\text{KOH}$  Aq, or with hot  $\text{K}_2\text{CrO}_4$  Aq. Insol. in  $\text{H}_2\text{O}$ ; sol. in  $\text{KOH}$  Aq; acids withdraw  $\text{PbO}$  (Wöhler a. Liebig, *P.* 21, 580). Another basic salt,  $2(\text{PbCrO}_4) \cdot \text{PbO}$ , occurs native as *Melanochromite*, and is said to be formed by diffusing  $\text{K}_2\text{CrO}_4$  Aq and  $\text{PbNO}_3$  Aq (Drevermann, *A.* 87, 120). Lead chromates are used as pigments.

**Lithium chromate**  $\text{Li}_2\text{CrO}_4 \cdot \text{H}_2\text{O}$ ; red trimetric crystals, easily sol. in  $\text{H}_2\text{O}$ . A double salt,  $\text{Li} \cdot \text{NH}_4 \cdot \text{CrO}_4 \cdot 2\text{H}_2\text{O}$ , is obtained by saturating  $\text{Li}_2\text{CrO}_4$  Aq with  $\text{NH}_4\text{Aq}$  (Rammelsberg, *B. B.* 1865, 629) (v. Dichromates).

**Magnesium chromate**  $\text{MgCrO}_4 \cdot 7\text{H}_2\text{O}$ . Citron-yellow soluble crystals; isomorphous with  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ ; S.G. 1.66–1.75; by dissolving  $\text{MgO}$  in  $\text{CrO}_3$  Aq and evaporating (Kopp, *A.* 42, 100; Graillich, *W. B.* 27, 174).

The double salt,  $\text{MgCrO}_4 \cdot \text{NH}_4\text{CrO}_4 \cdot 6\text{H}_2\text{O}$  crystallises from a solution of its constituents; yellow monoclinic crystals, isomorphous with corresponding double sulphates (Graillich, *l.c.*). v. also Potassium chromate.

**Manganese chromate.**—Basic manganous salt;  $\text{MnCrO}_4 \cdot \text{MnO} \cdot 2\text{H}_2\text{O}$ , brown pp. by reaction of boiling  $\text{MnSO}_4$  Aq and  $\text{K}_2\text{CrO}_4$  Aq (Fairrie, *C. J.* 4, 800; Freese, *P.* 140, 87; Warrington, *P. M.* [3] 21, 880; Reinsch, *P.* 55, 97).

**Mercury chromates.**—Mercurous chromate  $\text{Hg}_2\text{CrO}_4$ ; red crystalline powder; by reaction of

$\text{HgNO}_3\text{Aq}$  and  $\text{K}_2\text{CrO}_4\text{Aq}$  or  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$  (H. Rose, P. 53, 124; Freese, Z. [2] 6, 80). Decomposed by heat to  $\text{Hg}$ ,  $\text{O}$ , and  $\text{Cr}_2\text{O}_3$  (Darly, A. 65, 204; Freese, P. 140, 87). By action of alkalis a black basic salt,  $\text{Hg}_2\text{CrO}_4 \cdot 2\text{Hg}_2\text{O}$ , is obtained (Richter, B. 15, 1489).

**Mercuric chromate**  $\text{HgCrO}_4$ ; dark, garnet-red, trimetric prisms; obtained by evaporating equal parts of yellow  $\text{HgO}$  and  $\text{CrO}_3$  in  $\text{H}_2\text{O}$ . Decomposed by  $\text{H}_2\text{O}$  to  $\text{CrO}_3\text{Aq}$  and  $\text{HgCrO}_4 \cdot 2\text{HgO}$ . Decomposed by acids (Geuther, A. 106, 247; Millon, A. Ch. [8] 18, 886).

The basic salt  $\text{HgCrO}_4 \cdot 2\text{HgO}$  is a brick-red powder, obtained by boiling  $\text{HgO}$  with  $\text{K}_2\text{CrO}_4\text{Aq}$ , or by reaction of  $\text{Hg}_2\text{NO}_3\text{Aq}$  and  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$  (Millon, A. Ch. [8] 18, 886; Freese, Z. [2] 6, 80).

A double salt  $2(\text{HgCrO}_4) \cdot \text{HgS}$  is obtained by digesting freshly prep.  $\text{HgS}$  with solution of freshly prep.  $\text{HgO}$  in  $\text{CrO}_3\text{Aq}$ , and drying at  $80^\circ$ ; easily explodes when rubbed (Palm, J. 1862. 221) (v. also *Ammonium dichromate*).

**Nickel chromate**.—Basic salt<sup>4</sup>  
 $\text{NiCrO}_4 \cdot 2\text{NiO} \cdot 6\text{H}_2\text{O}$ ; brown pp. by reaction between  $\text{NiSO}_4\text{Aq}$  and  $\text{K}_2\text{CrO}_4\text{Aq}$ . Loses its  $\text{H}_2\text{O}$  above  $800^\circ$  (Freese, P. 140, 87). Other basic nickel chromates are described by Schmidt (A. 156, 19). A double compound,  $\text{NiCrO}_4 \cdot 6\text{NH}_3$ , is obtained in yellow dichroic crystals by addition of alcohol to a solution of the basic salt in presence of  $\text{NH}_3\text{Aq}$ ; the crystals lose  $\text{NH}_3$  in the air (Schmidt, l.c.).

**Potassium chromate**  $\text{K}_2\text{CrO}_4$ . S.G.  $\rho$  2.71, S.H. .189 (Kopp, A. Suppl. 3, 1). C.E. ( $0^\circ$ – $100^\circ$ ) .01134 (Joule a. Playfair, C. J. 1, 121; Schiff, A. 107, 64). S. ( $0^\circ$ ) 58.9; ( $20^\circ$ ) 62.94; ( $60^\circ$ ) 71.02; ( $100^\circ$ ) 79.1; boiling-point of saturated solution =  $104.2^\circ$  (Michel a. Kraft, A. Ch. [3] 41, 471; Schiff, A. 108, 326; v. Hauer, J. pr. 103, 114). Freezing-point of saturated solution =  $-12.5^\circ$  (Büding, P. 123, 337). S.G.  $\rho$  38.44 p.c. solution = 1.3787; 17.09 p.c. solution = 1.1476; 8.54 p.c. solution = 1.0708; 4.27 p.c. solution = 1.0349 (Michel a. Kraft, A. Ch. [3] 41, 417; Alluard, O. Rv 59, 500).

**Preparation**.—1. By heating 5 parts  $\text{K}_2\text{Cr}_2\text{O}_7$  with 4 parts  $\text{KNO}_3$  or  $\text{K}_2\text{CO}_3$  until the whole fuses quietly, dissolving in water, and crystallising.—2. By neutralising  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$  with  $\text{K}_2\text{CO}_3$ , evaporating and crystallising.—3. By fusing  $\text{Cr}_2\text{O}_3$  with  $\text{K}_2\text{CO}_3$  and  $\text{KNO}_3$ , dissolving in water and crystallising.—4. By fusing chrome-ironstone with  $\text{K}_2\text{CO}_3$  and  $\text{CaO} \cdot \text{H}_2\text{O}$ , lixiviating with  $\text{H}_2\text{O}$ , boiling down, and crystallising.

**Properties**.—Pale lemon-yellow, double six-sided trimetric pyramids; isomorphous with  $\text{K}_2\text{SO}_4$ . Melts without change. Insol. alcohol. Solution in  $\text{H}_2\text{O}$  is alkaline, with metallic taste, and is poisonous; on evaporation, this solution gives crystals of  $\text{K}_2\text{CrO}_4$ , and mother liquor gives crystals of  $\text{K}_2\text{CrO}_4$ .

**Reactions**.—1. *Acids*, even  $\text{CO}_2\text{Aq}$ , produce  $\text{K}_2\text{Cr}_2\text{O}_7$  (Schweitzer, N. R. P. 8, 212; Marguerite, J. pr. 64, 502; Mohr, Fr. 1872. 278).—2. Reduced by  $\text{H}_2\text{S}$  or  $\text{K}_2\text{SAq}$ , with formation of  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ , and by  $\text{SO}_2\text{Aq}$  with production of  $\text{Cr}_2\text{SO}_4\text{Aq}$ .—3. With  $\text{HCl}$  gas,  $\text{KCl}$ ,  $\text{H}_2\text{O}$ , and  $\text{K}_2\text{Cr}_2\text{O}_7$  are formed, and then the  $\text{K}_2\text{Cr}_2\text{O}_7$  is reduced to  $\text{CrCl}_3$  and  $\text{CrO}_3$  (Thomas, O. J. 83, 871).

**Combinations**.—1. With various chromates to

form double salts.  $\text{K}_2\text{CrO}_4 \cdot (\text{NH}_4)_2\text{CrO}_4$  crystallises from conc.  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$  saturated with  $\text{NH}_3$  (Berthier, A. Ch. [3] 7, 77; Johnson, J. pr. 62, 261).  $\text{K}_2\text{CrO}_4 \cdot \text{CaCrO}_4 \cdot 2\text{H}_2\text{O}$  crystallises from  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$  neutralised by  $\text{CaO} \cdot \text{H}_2\text{O}$ .

$\text{K}_2\text{CrO}_4 \cdot 5\text{CaCrO}_4$ , obtained by slowly evaporating a mixture of  $\text{CaCl}_2\text{Aq}$  and  $\text{K}_2\text{CrO}_4\text{Aq}$  (Bahr, J. pr. 60, 60; Duncan, J. pr. 50, 54; Rammelsberg, P. 98, 507).  $\text{K}_2\text{CrO}_4 \cdot 2\text{CuCrO}_4 \cdot \text{CuO} \cdot 2\text{H}_2\text{O}$ , obtained by reaction between cold  $\text{CuSO}_4\text{Aq}$  and  $\text{K}_2\text{CrO}_4\text{Aq}$ , or by adding  $\text{KOHAc}$  to mixture of  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$  and  $\text{CuSO}_4\text{Aq}$  (Freese, P. 140, 87).  $\text{K}_2\text{CrO}_4 \cdot \text{Fe}_3\text{CrO}_4 \cdot 4\text{H}_2\text{O}$ , by reaction between conc.  $\text{FeCl}_3\text{Aq}$  and  $\text{K}_2\text{CrO}_4\text{Aq}$ , dissolving pp. in  $\text{HClAc}$ , cooling, and washing rapidly with cold  $\text{H}_2\text{O}$  (Hengson, B. f2, 1800 a. 1656).  $\text{K}_2\text{CrO}_4 \cdot \text{MgCrO}_4 \cdot 2\text{H}_2\text{O}$ ; by evaporating conc.  $\text{K}_2\text{CrO}_4\text{Aq}$  after neutralising by  $\text{MgO}$  or  $\text{MgCO}_3$  (Hauer, J. pr. 80, 222; Schweitzer, A. 64, 276).  $\text{K}_2\text{CrO}_4 \cdot 2\text{ZnCrO}_4 \cdot 2\text{ZnO} \cdot 3\text{H}_2\text{O}$ ; by prolonged action of cold  $\text{ZnSO}_4\text{Aq}$  on excess of  $\text{K}_2\text{CrO}_4\text{Aq}$  (Freese, B. 2, 476; Prüssen a. Philippowa, A. 149, 92).—2. With *mercuric chloride* and *cyanide*, to form  $\text{K}_2\text{CrO}_4 \cdot 2\text{HgCl}_2$ , and  $2\text{K}_2\text{CrO}_4 \cdot 3\text{Hg}(\text{CN})_2$ , respectively (Darly, A. 65, 204; Rammelsberg, A. 28, 217; 84, 281) (v. also Di-, Tri-, and Tetra-chromates; also Bromo-, Chloro-, Fluor-, Iodo-, Chromates).

**Rubidium chromate**  $\text{Rb}_2\text{CrO}_4$ . Yellow trimetric crystals, isomorphous with  $\text{K}_2\text{CrO}_4$  and  $\text{K}_2\text{SO}_4$  (Piccard, J. pr. 86, 449; Grandeau, A. Ch. [3] 67, 155).

**Silver chromate**  $\text{Ag}_2\text{CrO}_4$ . Dark-red crystals; by reaction between  $\text{K}_2\text{CrO}_4\text{Aq}$  and  $\text{AgNO}_3\text{Aq}$ , or by digesting moist  $\text{Ag}_2\text{O}$  with  $\text{K}_2\text{CrO}_4\text{Aq}$ . Insol.  $\text{H}_2\text{O}$ ; sol. acids,  $\text{NH}_4\text{Aq}$ , and alkali chromates;  $\text{KOHAc}$  withdraws all  $\text{CrO}_3$ . Under  $\text{H}_2\text{O}$  is slowly reduced by  $\text{Zn}$ ,  $\text{Cd}$ ,  $\text{Sn}$ , &c. (Freese, P. 140, 87; Fischer, P. 8, 488). Combines with  $\text{NH}_3$  to form  $\text{Ag}_2\text{CrO}_4 \cdot 4\text{NH}_3$ ; produced in yellow crystals, isomorphous with corresponding sulphate and selenate, by dissolving  $\text{Ag}_2\text{CrO}_4$  in hot  $\text{NH}_4\text{Aq}$  and crystallising (Mitscherlich, P. f2, 141; Wöhler a. Rantenberg, A. 114, 119).

**Sodium chromate**  $\text{Na}_2\text{CrO}_4 \cdot 10\text{H}_2\text{O}$ ; yellow, deliquescent crystals, isomorphous with  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ . Prepared similarly to  $\text{K}_2\text{CrO}_4$  (Johnson, J. pr. 62, 261; Kopp, A. 42, 100) (v. also *Dichromates*).

**Thallium chromate**  $\text{Tl}_2\text{CrO}_4$ . Yellow pp. obtained by reaction between  $\text{K}_2\text{CrO}_4\text{Aq}$  and neutral solution of a thallous salt (Carstanjen, J. pr. 102, 65 a. 129; Heberling, A. 134, 11; Strecker, A. 135, 207; Crookes, C. N. 8, 255) (v. also Di-, and Tri-chromates).

**Thorium chromate**  $\text{Th}_2\text{CrO}_4 \cdot 8\text{H}_2\text{O}$ ; crystallises by evaporating a solution of  $\text{Th}_2\text{O}_3$  in  $\text{CrO}_3\text{Aq}$  (Chydenius, P. f19, 43).

**Zinc chromates**.—Various basic salts are obtained by the reactions between  $\text{ZnSO}_4\text{Aq}$  and  $\text{K}_2\text{CrO}_4\text{Aq}$ : the most marked seems to be  $\text{ZnCrO}_4 \cdot \text{ZnO} \cdot 2\text{H}_2\text{O}$  (Sarzeau a. Malaguti, A. Ch. [3] 9, 481; Thomson, P. M. 8, 81; Prüssen a. Philippowa, A. 149, 92). By dissolving this salt in a little  $\text{NH}_4\text{Aq}$ , and adding alcohol,  $\text{ZnCrO}_4 \cdot 4\text{NH}_3 \cdot 3\text{H}_2\text{O}$  is obtained (Sarzeau a. Malaguti, l.c.; Bieler, A. 151, 228) (v. also *Potassium chromate*).

**Chromates of In** (Meyer, A. 150, 187); **Mo**; **Sr**; **Sn** (Leykauf, J. pr. 19, 127); and **Yb** (Popp, A. 181, 179) seem to exist, but very

little is known concerning them, nor have their compositions been satisfactorily determined.

**Fluo-, Bromo-, Chloro-, and Iodo-chromates;** also **Amido-chromates** (*v. supra* beginning of this art., p. 154). Salts derived from the hypothetical acids, *fluochromic*  $\text{CrO}_2\text{F.OH}$ , *bromochromic*  $\text{CrO}_2\text{Br.OH}$ , &c., and *amidochromic*  $\text{CrO}_2\text{NH}_2\text{OH}$ . These acids are not themselves known.

**Potassium fluochromate**  $\text{CrO}_2\text{F.OK}$ . Ruby red, semitransparent, crystals; efflorescent in air; melts when heated; acts on glass. Prepared by heating powdered  $\text{K}_2\text{Cr}_2\text{O}_7$  in a Pt dish with excess of conc.  $\text{HFAg}$  (Streng, *A.* 129, 225; Heintze, *J. pr.* [2] 4, 225; Varenne, *C. R.* 89, 358; 91, 389).

**Potassium bromochromate**  $\text{CrO}_2\text{Br.OK}$ . Dark-brown crystals; gives up Br in an exsiccator; decomposed by  $\text{H}_2\text{O}$ . Obtained by saturating conc.  $\text{K}_2\text{Cr}_2\text{O}_7$  with fuming  $\text{HBrAg}$ , and crystallising from  $\text{HBrAg}$  (Heintze, *J. pr.* [2] 4, 225).

**Potassium chlorochromate**  $\text{CrO}_2\text{Cl.OK}$ . Obtained by heating for a short time 3 parts  $\text{K}_2\text{Cr}_2\text{O}_7$  with 4 parts conc.  $\text{HClAg}$  and a little  $\text{H}_2\text{O}$ , and cooling; or by adding  $\text{CrO}_2\text{Cl}_2$  to  $\text{KClAg}$ , or to  $\text{K}_2\text{Cr}_2\text{O}_7$  slightly acidified with acetic acid:

(Péligot, *A. Ch.* 52, 267; Geuther, *A.* 106, 240). This salt is also produced, along with  $\text{Cr}_2\text{O}_3$ , when violet  $\text{CrCl}_3$  reacts with molten  $\text{K}_2\text{Cr}_2\text{O}_7$  (Geuther, *A.* 118, 68). Large red prisms; S.G.  $^{\circ}$  2.497; C.E. ( $0^{\circ}$ - $100^{\circ}$ ) .0159 (Playfair *A.* Joule, *C. J.* 1, 121). May be crystallised unchanged from  $\text{H}_2\text{O}$  containing a little acid; crystals of  $\text{K}_2\text{Cr}_2\text{O}_7$  separate from an aqueous solution. Cl is evolved at  $100^{\circ}$ . Decomposed by conc.  $\text{H}_2\text{SO}_4$  with formation of  $\text{CrO}_2\text{Cl}_2$  and  $\text{CrO}_2\text{Cl}$  (q. v.); with  $\text{NO}_2$  gives  $\text{NO}_2\text{Cl}$  (Heintze, *J. pr.* [2] 4, 211). By reaction with conc.  $\text{KCNAg}$ ,  $\text{CNCl}$  is formed. By the action of dry  $\text{NH}_3$ , salt having the composition  $\text{K}_2\text{Cr}_2\text{O}_7$  ( $?\text{CrO}_2\text{OK.CrO}_2\text{OK.CrO}_2$ ) is formed, along with  $\text{KCl}$  and  $\text{NH}_4\text{Cl}$ ; if the chlorochromate is suspended in  $(\text{C}_2\text{H}_5)_2\text{O}$  and  $\text{NH}_3$  is passed in, crystals of potassium amidochromate  $\text{CrO}_2\text{NH}_2\text{OK}$  (q. v.) are formed (Heintze, *J. pr.* [2] 4, 211).

**Chlorochromates of Na—** $\text{CrO}_2\text{Cl.ONa.2H}_2\text{O}$ ; of  $\text{NH}_4$ — $\text{CrO}_2\text{Cl.ONH}_4$ ; of  $\text{Ca}$ ,  $\text{Sr}$ ,  $\text{Ba}$ ,  $\text{Mg}$ ,  $\text{Ni}$ ,  $\text{Co}$ , and  $\text{Zn}$ — $(\text{CrO}_2\text{Cl.O})_2\text{M.xH}_2\text{O}$ ; have also been prepared, by adding  $\text{CrO}_2\text{Cl}_2$  to fairly conc. solution of the metallic carbonates in  $\text{CrO}_2\text{Ag}$ . When  $\text{M} = \text{Mg}$ ,  $\text{Ni}$ ,  $\text{Co}$ , or  $\text{Zn}$ , the salts crystallise with  $9\text{H}_2\text{O}$ ; when  $\text{M} = \text{Ca}$ , with  $5\text{H}_2\text{O}$ ; when  $\text{M} = \text{Sr}$ , with  $4\text{H}_2\text{O}$ ; and when  $\text{M} = \text{Ba}$ , with  $\text{H}_2\text{O}$  (Péligot, *A. Ch.* 52, 267; Prætorius, *A.* 201, 1).

**Potassium iodochromate**  $\text{CrO}_2\text{I.OK}$ . Obtained, as garnet-red, easily decomposed, crystals, by gently heating conc. colourless  $\text{HIAg}$  with finely powdered  $\text{K}_2\text{Cr}_2\text{O}_7$  (Guyot, *C. R.* 73, 46).

**Potassium amidochromate**  $\text{CrO}_2\text{NH}_2\text{OK}$ . Finely powdered  $\text{CrO}_2\text{Cl.OK}$  is slowly added to water and ether (free from alcohol), the liquid is simultaneously saturated with  $\text{NH}_3$ ; after standing 24 hours, the ether is poured off, the residue is gently warmed to get rid of adhering ether, and is then treated with water; the liquid is evapo-

rated at a low temperature, and allowed to crystallise. The salt is recrystallised from  $\text{H}_2\text{O}$ , and the crystals are dried at  $100^{\circ}$ . Garnet-red, unchanged by cold  $\text{H}_2\text{O}$ , or cold  $\text{NaOHAg}$ ; decomposed by  $\text{H}_2\text{O}$ , or  $\text{NaOHAg}$ , at  $100^{\circ}$ , giving  $\text{CrO}_2\text{OK.ONH}_4$ , and  $\text{CrO}_2\text{OK.ONa}$ , respectively; decomposed by nitrous acid to  $\text{K}_2\text{Cr}_2\text{O}_7$ ,  $\text{N}$ , and  $\text{H}_2\text{O}$ .  $\text{CrO}_2\text{NH}_2\text{OK}$  is changed by dry  $\text{NH}_3$  to a dark-brown powder, from which  $\text{H}_2\text{O}$  removes  $\text{NH}_4\text{Cl}$  and leaves a crystalline salt,  $\text{Cr}_2\text{O}_3(\text{OK})_2$ ; the corresponding  $\text{NH}_4$  salt is obtained by acting on  $\text{CrO}_2\text{Cl}_2$  dissolved in  $\text{CHCl}_3$  with  $\text{NH}_3$ , and reacting with  $\text{H}_2\text{O}$  (Heintze, *J. pr.* [2] 4, 214).

**Dichromates**  $\text{M}_2\text{Cr}_2\text{O}_7$  and  $\text{M.Cr}_2\text{O}_7$ . Most of these salts are soluble in water; many of them are decomposed by water. The greater number are salts of monovalent metals. They are obtained by the action of acids on  $\text{M}_2\text{Cr}_2\text{O}_7$ .

**Ammonium dichromate**  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$ . Orange coloured, monoclinic, crystals; S.G. 2.387; decomposed by heat to  $\text{Cr}_2\text{O}_3$ ,  $\text{H}_2\text{O}$ , and  $\text{N}$ . Prepared by neutralising  $\text{CrO}_2\text{Ag}$  with  $\text{NH}_4\text{Ag}$ , adding an equal quantity of  $\text{CrO}_2\text{Ag}$ , and evaporating (Richmond *A.* Abel, *C. J.* 3, 199; Siewert, *Z. f. d. g. Naturwiss.* 19, 11; Schabus, *P.* 116, 420; Weiss, *Sitz. W.* 37, 373; Rammelsberg, *P.* 118, 158; Schiff, *A.* 107, 64). Two double compounds with  $\text{HgCl}_2$ , viz.  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7.\text{HgCl}_2.\text{H}_2\text{O}$ , and  $3(\text{NH}_4)_2\text{Cr}_2\text{O}_7.\text{HgCl}_2$ , exist (Darby, *A.* 65, 204; Zepharovich, *Sitz. W.* 39, 17; Clarke *A.* Stern, *Am.* 3, 351).

**Barium dichromate**  $\text{BaCr}_2\text{O}_7.2\text{H}_2\text{O}$ ; yellow needles, obtained by dissolving  $\text{BaCrO}_4$  in conc.  $\text{CrO}_2\text{Ag}$ , evaporating, crystallising, and drying at  $100^{\circ}$ . Decomposed by  $\text{H}_2\text{O}$  to  $\text{BaCrO}_4$  and  $\text{CrO}_2\text{Ag}$  (Bahr, *J. pr.* 60, 30; Zettnow, *P.* 144, 167; Preis *A.* Rayman, *B.* 13, 340).

**Bismuth dichromate.**—The salt  $2(\text{Bi}_2\text{Cr}_2\text{O}_7).\text{Bi}_2\text{O}_3$ , obtained by ppg.  $\text{Bi}_2\text{NO}_3$  in  $\text{HNO}_3\text{Ag}$  by  $\text{K}_2\text{CrO}_4\text{Ag}$ , described as a basic bismuth chromate (p. 155), may perhaps be better regarded as basic bismuth dichromate  $(\text{BiO})_2\text{Cr}_2\text{O}_7$ .

**Calcium dichromate**  $\text{CaCr}_2\text{O}_7.3\text{H}_2\text{O}$ ; deliquescent, red, crystals; obtained by dissolving  $\text{CaCrO}_4$  in  $\text{CrO}_2\text{Ag}$  and evaporating (Bahr, *J. pr.* 60, 60).

**Copper dichromate**  $\text{CuCr}_2\text{O}_7.2\text{H}_2\text{O}$ ; brown-black, deliquescent, crystals; e. sol. in  $\text{H}_2\text{O}$  or alcohol; decomposed\* by hot  $\text{H}_2\text{O}$  with separation of  $\text{CuCrO}_4.2\text{CuO}$ ; obtained by dissolving  $\text{CuO.H}_2$  in conc.  $\text{CrO}_2\text{Ag}$ , and evaporating (Droge, *A.* 101, 39).

**Lead dichromate**  $\text{PbCr}_2\text{O}_7$ . Brick red, crystalline, powder; by action of  $\text{CrO}_2\text{Ag}$  on  $\text{PbCrO}_4$  (Preis *A.* Rayman, *B.* 13, 340).

**Lithium dichromate**  $\text{Li}_2\text{Cr}_2\text{O}_7$ ; black-brown, deliquescent, crystals (Rammelsberg, *B.* 1865, 429).

**Potassium dichromate**  $\text{K}_2\text{Cr}_2\text{O}_7$ . S.G.  $^{\circ}$  2.692 (Joule *A.* Playfair, *C. J.* 1, 121; Schiff, *A.* 107, 64). M.P. about  $400^{\circ}$  (Tilden *A.* Shenstone, *T.* 1884, 34). S.H. 186 (Kopp, *A. Suppl.* 3, 1 a. 289). C.E. ( $0^{\circ}$ - $100^{\circ}$ ) .0122 (Joule *A.* Playfair, *C. J.* 1, 121). S. ( $0^{\circ}$ ) 4.9; ( $10^{\circ}$ ) 8.4; ( $40^{\circ}$ ) 29.2; ( $80^{\circ}$ ) 73; ( $100^{\circ}$ ) 102; ( $117^{\circ}$ ) 128.8; ( $129^{\circ}$ ) 153.8; ( $148^{\circ}$ ) 200.6; ( $180^{\circ}$ ) 262.7. S.G. of solution 6.08 parts in 100 water = 1.0405 at  $19^{\circ}$ ; of 13.1 parts in 100 water = 1.0847; saturated solution boils at  $104^{\circ}$ ; insol. alcohol (Kremers, *P.* 92, 497; 95, 110; 96, 89; Alluard, *C. R.* 59,

600; Michel & Kraft, *A. Ch.* [8] 41, 471; Tilden & Shenstone, *T.* 175, 28).

**Preparation.**—Chrome-ironstone is heated, powdered, and mixed with  $K_2CO_3$  and  $CaO$ ; the mixture is heated to  $150^\circ$  until quite dry, then to bright redness, in presence of air, with frequent stirring. The fused mass is allowed to cool, and is then treated with a small quantity of boiling water; if the solution contains  $CaCrO_4$  it is decomposed by adding  $K_2CO_3$ , and filtering from  $CaCO_3$ . Sufficient acid to change the  $K_2CrO_4$  to  $K_2Cr_2O_7$  is added, the liquid is evaporated and allowed to crystallise. The crystals are purified by recrystallisation from water.

**Properties.**—Large, red, triclinic, crystals; unchanged in air. Solution in water is acid to litmus, has a metallic taste, and is poisonous. Is rapidly changed by light in presence of organic matter; hence used in photography (Schwann, *D. P. J.* 189, 130). Decomposed at white heat to  $K_2CrO_4$ ,  $O$ , and  $Cr_2O_3$ .

**Reactions.**—Reduced by heating with  $C$ ,  $S$ , or  $NH_4Cl$ ; or with solid  $H_2C_2O_4$  (Bothamley, *C. J.* 51, 159; Werner, *C. J.* 53, 602);  $K_2Cr_2O_7$  is reduced by  $SO_2$  to  $Cr_2(SO_4)_3$ , and by  $H_2S$  to  $Cr_2O_3$  and  $S$ ;  $NO$  is absorbed and after a time  $CrO_3$  is ppd. (Vogel, *J. pr.* 77, 482). Heated with conc.  $H_2SO_4$ ,  $K_2SO_4$ ,  $Cr_2(SO_4)_3$ ,  $H_2O$ , and  $O$  are produced; addition of 2 formula-weights  $H_2SO_4$  to a boiling solution of one formula-weight  $K_2Cr_2O_7$ , produces pp. of orange-red  $HKSO_4 \cdot K_2Cr_2O_7$ , which is decomposed by  $H_2O$  (Schwarz, *D. P. J.* 186, 81). Solution of  $K_2Cr_2O_7$  in conc.  $HCl$  gives  $CrO_2 \cdot ClOK$  (*q. v.*) on cooling. From a hot solution of the salt in 12 parts  $HNO_3$ , carmine-red crystals of  $Cr_2O_3 \cdot NO_3 \cdot OK$  ( $?OK \cdot CrO_3 \cdot O \cdot CrO_3 \cdot NO_3$ ) separate on cooling; by re-crystallising this salt from  $HNO_3$ , the salt  $Cr_2O_3 \cdot NO_3 \cdot OK$  ( $?OK \cdot CrO_3 \cdot O \cdot CrO_3 \cdot O \cdot CrO_3 \cdot NO_3$ ) is obtained (Darmstadt, *B.* 4, 117). A double compound  $K_2Cr_2O_7 \cdot HgCl_2$  is obtained by evaporating a mixture of its constituents (Darby, *A.* 65, 204; Hahn, *Ar. Ph.* [2] 99, 147).

**Rubidium dichromate**  $Rb_2Cr_2O_7$ ; and **Sodium dichromate**,  $M_2Cr_2O_7$ ; closely resemble  $K_2Cr_2O_7$ , (Picard, *J. pr.* 86, 449; Grandeau, *A. Ch.* [3] 87, 155).

**Silver dichromate**  $Ag_2Cr_2O_7$ . By pp.  $K_2Cr_2O_7$  by  $AgNO_3$ , or digesting moist  $Ag_2O$  with  $K_2Cr_2O_7$ ; somewhat soluble in  $H_2O$ , crystallising in red, triclinic, crystals; decomposed by boiling water; when strongly heated gives  $Cr_2O_3$  and  $Ag$  (Fresenius, *P.* 140, 87; Warington, *P. M.* 11, 489; Teschemacher, *P. M.* 1, 845; Nason, *A.* 104, 126).

**Thallium dichromate**  $Tl_2Cr_2O_7$ . Red, crystalline, powder; insol. in  $H_2O$ ; decomposed by conc. acid to  $Tl_2Cr_2O_5$  (*q. v. infra*). Obtained by reaction of thallous salts with  $K_2Cr_2O_7$ .

**Tri-, Tetra-, and Hexa-Chromates:**  $M_3Cr_2O_7$ ,  $M_4Cr_2O_7$ , and  $M_6Cr_2O_7$ . Very few of these salts are known.  $(NH_4)_3Cr_2O_7$ ,  $K_3Cr_2O_7$ , and  $Tl_3Cr_2O_7$  are obtained by crystallising solutions of the dichromates in  $HNO_3$  (Siewert, *Z. f. d. g. Naturwiss.* 19, 11; Bothe, *J. pr.* 46, 184; Hauer, *Sitz.* W. 39, 439; Willm, *A. Ch.* [4] 5; 5).  $K_3Cr_2O_7$  is obtained by long-continued digestion of  $K_2Cr_2O_7$  in conc.  $HNO_3$  (Siewert, *l.c.*).  $(NH_4)_4Cr_2O_7 \cdot 10H_2O$  was obtained by Rammelsberg (*P.* 94, 507) from a solution of  $(NH_4)_2Cr_2O_7$ .

**Chromites.** *Compounds of  $Cr_2O_3$  with more positive metallic oxides.* A compound  $2CaO \cdot Cr_2O_3$  is obtained, according to Chancel (*C. R.* 43, 97), by the reaction between  $NH_4Ag$  and chrome-alum solution mixed with  $CaCl_2$ . By mixing solutions in  $KOHAq$  of  $Cr_2O_3$  and  $PbO$  or  $ZnO$ , pps. are obtained of the composition  $MO \cdot Cr_2O_3$  (Pelouze, *A. Ch.* [3] 33, 5). Compounds of the form  $MO \cdot Cr_2O_3$ , where  $M = Mn$ , or  $Zn$ , are also produced by fusing together the component oxides with  $B_2O_3$  at a white heat; the compounds crystallise out on cooling;  $ZnO \cdot Cr_2O_3$  forms dark green octahedra, S.G. 5.809;  $MnO \cdot Cr_2O_3$ , hard iron-grey octahedra, S.G. 4.87 (Ebelmen, *A. Ch.* [3] 33, 34). These compounds may be regarded as chromites,  $MCr_2O_3$ , i.e. salts of the hypothetical chromous acid  $H_2Cr_2O_4$ . Certain metallic oxides which are insoluble in  $KOHAq$  become soluble therein when mixed with  $Cr_2O_3 \cdot xH_2O$ ; e.g. a mixture of  $Cr_2O_3 \cdot xH_2O$  with 40 p.c.  $Fe_2O_3$ , 12.5 p.c.  $MnO$ , 20 p.c.  $CoO$ , or 25 p.c.  $NiO$ , is completely soluble in  $KOHAq$ ; on the other hand  $Cr_2O_3$  is completely ppd. by  $KOHAq$  in presence of 80 p.c.  $Fe_2O_3$ , 60 p.c.  $MnO$ , or 60 p.c.  $CoO$  or  $NiO$  (Church, *Ph. O.* 1853, 391).

**Chromium, alloys of.** An alloy of  $Cr$  with  $Al$  is described by Wöhler (*A.* 106, 118) as very fusible, tin-white, crystals; becoming brittle after fusion; S.G. 4.9. Fremy (*C. R.* 44, 632) obtained an alloy with  $Fe$  by reducing chrome-ironstone with  $C$ , or by the action of  $Fe$  on  $Cr_2O_3$  at a very high temperature; long needles, harder than steel. By the action of  $Na$  amalgam on  $CrCl_3$  an amalgam of  $Cr$  with  $Hg$  is produced (Vincent, *P. M.* [4] 24, 328; Schönbein, *P.* 112, 445).

**Chromium, ammonio-salts of; or Chrom-ammonium salts.** Freshly ppd.  $Cr_2O_3 \cdot xH_2O$  dissolves in conc.  $NH_4Cl$  containing  $NH_4Ag$ ; on standing in air a reddish-violet powder is deposited; when this is dissolved in cold  $HCl$  and excess of conc.  $HCl$  is added, a rose-red crystalline powder is produced having the composition  $Cr_2Cl_2 \cdot 8NH_3 \cdot 2H_2O$ . By treating this salt with cold conc.  $H_2SO_4$ , a new compound  $Cr_2Cl_2(SO_4)_2 \cdot 8NH_3 \cdot 2H_2O$  is produced; by the action of  $BaI_2$  on this, the salt  $Cr_2Cl_2I_2 \cdot 8NH_3 \cdot 2H_2O$  is formed; and from this,  $Cr_2Cl_2Br_2 \cdot 8NH_3 \cdot 2H_2O$  may be obtained by the action of conc.  $HBr$ . Various other derivatives are known of the general form  $Cr_2M_2X_2 \cdot 8NH_3 \cdot xH_2O$ , in which  $M = Cl, Br$ , or  $I$ , and  $X =$  negative radicle,  $Cl, Br, I, NO_3$ ,  $CrO_3$ .

&c. The reactions of this series of compounds forbid us to regard them as ordinary double compounds of  $Cr_2M_2$  with  $xNH_3$ ; they are usually looked on as compounds of the hypothetical groups, *chlorochrom-*, *bromochrom-*, *iodochrom-*, *tetrammonium*, with negative radicles  $Cl$ ,  $(NO_3)_2$ , &c. On this supposition the formula  $N_4H_{12}(NH_4)_2(Cr_2M_2)X_2$  would represent the compounds in question; the names *chloro-* (bromo-, iodo-) *chromtetrammonium chloride*, *bromide*, *iodide*, &c., are used. The less hypothetical formula  $M_2Cr_2 \cdot 8NH_3 \cdot X_2$  is also frequently employed to represent the chloro(&c.)chromtetrammonium compounds.

Six other series of chromammonio-com-

pounds are known. They may all be represented by the general form  $\text{Cr}_x\text{NH}_3\text{X}_x$ , where  $x = 10$  or 12, and  $X =$  negative radicle; in some of these part of the  $X_x$  is easily replaced by other radicles and parts not; in others the whole of the  $X_x$  is easily replaced. If  $M$  represent the radicle which is replaced with difficulty, and  $X$  the radicle which is easily replaced, we get the developed general formula for the seven series of compounds  $M_x\text{Cr}_x\cdot 8(10 \text{ or } 12)\text{NH}_3\text{X}_x$ ; where  $x = 1$ , or 2, and  $s = 4, 5$ , or 6. The second to seventh series may also be regarded as derived from the first (i.e. from the chloro-(&c.)chrom-tetrammonium salts, by replacing  $H$  in  $NH_4(NH_3)_6(\text{Cr}_2M_2)X_4$  by the radicle  $NH_3$ . The following formulae represent the seven series of compounds:—

- (1)  $M_x\text{Cr}_x\cdot 8NH_3X_x$  or  $N_4H_8(NH_3)_4(\text{Cr}_2M_2)X_4$   
*Chromtetrammonium salts.*
- (2)  $M_x\text{Cr}_x\cdot 10NH_3X_x$  or  $N_4H_{10}(NH_3)_4(\text{Cr}_2M_2)X_4$   
*Purpureochrom salts.*
- (3)  $\text{Cr}_x\cdot 10NH_3X_x$  or  $N_4H_{10}(NH_3)_4\text{Cr}_2X_4$   
*Roseochrom salts.*
- (4)  $M_x\text{Cr}_x\cdot 10NH_3X_x$  or  $N_4H_{10}(NH_3)_4(\text{Cr}_2M_2)X_4$   
*Xanthochrom salts; ( $M_2 = 2NO_2$ ).*
- (5)  $\text{Cr}_x\cdot 12NH_3X_x$  or  $N_4H_{12}(NH_3)_4\text{Cr}_2X_4$   
*Luteochrom salts.*
- (6) & (7)  $M_x\text{Cr}_x\cdot 10NH_3X_x$  or  $N_4H_{10}(NH_3)_4(\text{Cr}_2M_2)X_4$   
*Rhodochrom and Erythrochrom salts; ( $M = OH$ ).*

The purpureo- and roseo- salts are isomeric, using the term in a rather wider sense than is given to it in organic chemistry as the molecular weights of none of these salts are known;  $\text{AgNO}_3$  aq pps.  $\frac{2}{3}$  of the  $\text{Cl}$  from purpureochromium chloride in the cold, but all the  $\text{Cl}$  from roseochromium chloride;  $\text{HNO}_3$  aq,  $\text{HBr}$  aq, &c., also removes  $\frac{2}{3}$  of the  $\text{Cl}$  from the former salts; boiling  $\text{HIAq}$ , however, produces  $\text{L}_2\text{Cr}_2\cdot 10NH_3\text{I}_4$  (iodopurpureochromium iodide); and by acting on this with dilute  $\text{HCl}$  aq,  $\text{L}_2\text{Cr}_2\cdot 10NH_3\text{Cl}_4$  (iodopurpureochromium chloride) is obtained. Purpureo- compounds, in which  $M$ , and  $X$ , are the same radicle (e.g.  $\text{Br}_2\text{Cr}_2\cdot 10NH_3\text{Br}_4$ , or  $\text{Cl}_2\text{Cr}_2\cdot 10NH_3\text{Cl}_4$ ) easily change to roseo- compounds by standing in the air, or by heating. Xanthochromium chloride is obtained by the action of  $\text{NaNO}_3$  aq and dilute  $\text{HNO}_3$  aq on  $\text{Cl}_2\text{Cr}_2\cdot 10NH_3\text{Cl}_4$ , or on  $\text{Cr}_2\cdot 10NH_3\text{Br}_4$ . The three series, purpureo- luteo- and rhodo- salts, are obtained by more or less slowly oxidising  $\text{Cr}_2\text{Cl}_4$  in  $\text{NH}_4\text{Cl}$  aq in presence of  $\text{NH}_3$  aq; the purpureo- and rhodo- salts are obtained by oxidising in presence of air, the luteo- salts in absence of air (v. *infra*). The roseo- and erythro- salts are obtained from the purpureo- and rhodo- respectively (v. *infra*). The rhodo- and erythro- salts are isomeric; the former change to the latter by standing in air (v. *infra*).

In the nomenclature of the chromtetrammonium and purpureochromium salts it is necessary to use prefixes, chloro-, bromo-, &c., to express the nature of the radicles  $M_x$ ; thus chloropurpureochromium chloride, and bromopurpureochromium nitrate, are  $\text{Cl}_2\text{Cr}_2\cdot 10NH_3\text{Cl}_4$ , and  $\text{Br}_2\text{Cr}_2\cdot 10NH_3(\text{NO}_3)_4$ , respectively. In the other series prefixes are unnecessary.

It will suffice here to describe the chief compounds in each series. The principal references

#### I. CHROMTETRAMMONIUM SERIES

$M_x\text{Cr}_x\cdot 8NH_3X_x\cdot xH_2O$ . *Chlorochromtetrammonium chloride*  $\text{Cl}_2\text{Cr}_2\cdot 8NH_3\text{Cl}_4\cdot 2H_2O$ . Deep-red, very lustrous, almost opaque, trimetric crystals. Obtained by digesting freshly ppd. chromium hydroxide in a closed flask with conc.  $\text{NH}_4\text{Cl}$  in  $\text{NH}_4\text{Aq}$ , until the hydroxide dissolves: the deep-red liquid is allowed to stand in the air, the dark-violet powder which separates is dissolved in cold  $\text{HCl}$  aq, excess of conc.  $\text{HCl}$  aq is added, the rose-red crystalline powder which separates out is washed with conc.  $\text{HCl}$  aq, then with strong alcohol, and is crystallised from warm  $H_2O$  containing a little  $\text{HCl}$ . This compound begins to decompose at  $120^\circ$ ; when strongly heated  $\text{NH}_3$ ,  $\text{NH}_4\text{Cl}$ , and  $H_2O$ , are given off, and  $\text{Cr}_2\text{O}_3$  remains; heated in air-free  $H_2$  or in  $\text{CO}_2$ ,  $\text{Cr}_2\text{OCl}_2$  remains. The salt is soluble in water, but on boiling  $\text{Cr}_2\text{O}_3\cdot xH_2O$  and  $\text{NH}_3$  are produced. Treated with  $H_2O$  and moist  $\text{Ag}_2O$ , a liquid is obtained probably containing  $\text{Cl}_2\text{Cr}_2\cdot 8NH_3(\text{OH})_4$ ; it soon decomposes with evolution of  $\text{NH}_3$ .

The sulphate  $\text{Cl}_2\text{Cr}_2\cdot 8NH_3(\text{SO}_4)_2\cdot 2H_2O$  is obtained by treating the chloride with cold conc.  $\text{H}_2\text{SO}_4$ , and then with  $H_2O$ ; from this the iodide ( $X = I$ ) is produced by the action of  $\text{BaI}_2$  aq, and by the action of fuming  $\text{HBr}$  aq on this, the bromide ( $X = \text{Br}$ ) is produced.

If freshly ppd.  $\text{Cr}_2\text{O}_3\cdot xH_2O$  is treated with  $\text{NH}_4\text{Br}$  in  $\text{NH}_4\text{Aq}$ , bromochromtetrammonium bromide,  $\text{Br}_2\text{Cr}_2\cdot 8NH_3\text{Br}_4\cdot 2H_2O$  is produced; an aqueous solution of this salt dropped into conc.  $\text{HCl}$  aq gives the bromo-chloride ( $M = \text{Br}$ ,  $X = \text{Cl}$ ).

#### II. PURPUREOCHROMIUM SERIES

$M_x\text{Cr}_x\cdot 10NH_3X_x$ . *Chloropurpureochromium chloride*.  $\text{Cl}_2\text{Cr}_2\cdot 10NH_3\text{Cl}_4$ . Prepared by reducing  $\text{K}_2\text{Cr}_2\text{O}_7$  by alcohol and very conc.  $\text{HCl}$  aq, so that 12 g.  $\text{K}_2\text{Cr}_2\text{O}_7$  give 50 c.c.  $\text{CrCl}_3$  solution, pouring the liquid (from  $\text{KCl}$ ) through a separating funnel into a cylinder fitted with a reversed U-tube and an exit tube, and containing sticks of  $\text{Zn}$ , and adding a little  $\text{HCl}$  aq; when the liquid is the colour of  $\text{CuSO}_4$  aq (which indicates reduction to  $\text{CrCl}_3$ ), forcing it through the U-tube into a solution of 600 g.  $\text{NH}_4\text{Cl}$  in 1,000 c.c.  $\text{NH}_4\text{Aq}$ , S.G. .9; and repeating this operation until 50 g.  $\text{K}_2\text{Cr}_2\text{O}_7$  have been reduced, and the  $\text{CrCl}_3$  solution further reduced to  $\text{CrCl}_2$ , and driven into the ammoniacal  $\text{NH}_4\text{Cl}$  aq. The blue liquid is then oxidised, by long-continued passage of air, until it becomes deep carmine-red;  $2\frac{1}{2}$  litres of conc.  $\text{HCl}$  aq are added, the liquid is boiled for a few minutes, when the chloride separates out as a carmine-red crystalline powder. This liquid is allowed to cool, and poured off, the residue is washed free from  $\text{NH}_4\text{Cl}$  by conc.  $\text{HCl}$  aq + an equal volume of  $H_2O$ , collected on a filter and again washed with the same  $\text{HCl}$  aq, dissolved in  $H_2O$  slightly acidified with  $\text{H}_2\text{SO}_4$ , and re-ppd. by conc.  $\text{HCl}$  aq; the pp. is boiled with a little conc.  $\text{HCl}$  aq, washed with the same strength of  $\text{HCl}$  aq as before, then with 90 p.c. alcohol, and dried at about  $18^\circ$ – $20^\circ$ .

Chloropurpureo-chromium chloride crystallises in small carmine-red octahedra: S.G.  $1.427$

1.687; S. (16°) .65; insol. conc. HClAq; on boiling an aqueous solution roseochromium chloride is obtained; decomposed by heat, giving  $\text{Cr}_2\text{O}_3$ .

**Bromo-bromide** ( $\text{M}_2 = \text{Br}_2$ ,  $\text{X}_1 = \text{Br}$ ) is prepared similarly to the chloro-chloride, using  $\text{NH}_4\text{Br}$  in place of  $\text{NH}_4\text{Cl}$ , &c. By treatment with excess of HClAq it yields **bromo-chloride** ( $\text{M}_2 = \text{Br}_2$ ,  $\text{X}_1 = \text{Cl}$ ). By treating chloro-chloride with boiling conc. HIAq **iodo-iodide** ( $\text{M}_2 = \text{I}_2$ ,  $\text{X}_1 = \text{I}$ ) is formed. By the action of dilute  $\text{HNO}_3\text{Aq}$ ,  $\text{H}_2\text{SO}_4\text{Aq}$ , &c., on chloro-chloride, **chloro-nitrate**, **chloro-sulphate**, &c., are obtained ( $\text{M}_2 = \text{Cl}_2$ ,  $\text{X}_1 = 4\text{NO}_3$ ,  $2\text{SO}_4$ , &c.); the action of  $\text{K}_2\text{CrO}_4\text{Aq}$  produces **chloro-chromate** ( $\text{M}_2 = \text{Cl}_2$ ,  $\text{X}_1 = 2\text{CrO}_4$ ). Besides these the following compounds have been prepared:—

$\text{M}_2$	$\text{X}_1$	$\text{M}_2$	$\text{X}_1$	$\text{M}_2$	$\text{X}_1$
$\text{Cl}_2$	$2\text{SiF}_6$	$\text{Br}_2$	$2\text{PtBr}_4$	$\text{I}_2$	$\text{Cl}_2$
		$\text{Br}_2$	$4\text{NO}_3$	$\text{I}_2$	$4\text{NO}_3$
		$\text{Br}_2$	$2\text{CrO}_4$	$\text{I}_2$	$2\text{PtCl}_4$

**III. ROSEOCHROMIUM SERIES**  $\text{Cr}_2 \cdot 10\text{NH}_4 \cdot \text{X}_1$ . **Roseochromium chloride**,  $\text{Cr}_2 \cdot 10\text{NH}_4 \cdot \text{Cl}_2$ . Obtained by rubbing 5 g. dry chloropurpureo-chloride with the moist  $\text{Ag}_2\text{O}$  from 20 g.  $\text{AgNO}_3$  for a few minutes in a mortar, filtering, neutralising the alkaline liquid with HClAq, filtering from  $\text{AgCl}$ , evaporating in a rapid air-stream, pressing pp. between paper, washing once with a little  $\text{H}_2\text{O}$ , and drying in air out of direct sunlight. Orange-yellow crystals; v. sol.  $\text{H}_2\text{O}$ ; insol. alcohol; very unstable, giving off  $\text{NH}_3$ ; changed, as are all roseo- salts, by heating with conc. HClAq, to purpureo- salt.  $\text{AgNO}_3\text{Aq}$  pps. all the Cl in the cold.

The other roseo- salts are formed by neutralising the solution obtained by action of moist  $\text{Ag}_2\text{O}$  on purpureo-chloride by various acids; the solution in question probably contains roseo-hydroxide [ $\text{X}_1 = (\text{OH})$ ]. The chief roseo- salts are  $\text{X}_1 = \text{Br}$ ,  $\text{I}$ ,  $2\text{SO}_4$ ,  $6\text{NO}_3$ ,  $\text{Br}_2(\text{PtBr})_2$ ,  $(\text{SO}_4)_2\text{PtCl}_4$ ,  $\text{Br}_2(\text{CrO}_4)_2$ .

**IV. XANTHOCHROMIUM SERIES**  $(\text{NO}_3)_2 \cdot \text{Cr}_2 \cdot 10\text{NH}_4 \cdot \text{X}_1$ . **Xanthochromium chloride**,  $(\text{NO}_3)_2 \cdot \text{Cr}_2 \cdot 10\text{NH}_4 \cdot \text{Cl}_2$ . To 20 g. chloropurpureo-chloride 300 c.c. warm water and about 20 drops dilute  $\text{HNO}_3\text{Aq}$  are added, the liquid is slowly heated to boiling, then cooled, and filtered; the insoluble purpureo-chloride is again treated in the same way; 40–50 g. pure  $\text{NaNO}_3$  and 25 c.c. HClAq (12 p.c.) are added to the total liquid; the yellow crystalline salt which separates out is washed with water, then with alcohol, dissolved in water, and ppd. by fairly conc.  $\text{NH}_4\text{ClAq}$ . Xantho-chloride is a yellow crystalline powder; fairly sol.  $\text{H}_2\text{O}$ ; insol. alcohol; easily decomposed by acids with production of  $\text{HNO}_3$ ; treated with HClAq, chloropurpureo-chloride is formed; fairly stable towards alkalis; forms double salts with  $2\text{PtCl}_4$  and  $4\text{HgCl}_2$ .

The other most important xantho- salts are:  $\text{X}_1 = \text{Br}$ ,  $\text{I}$ ,  $2\text{SO}_4$ ,  $2\text{S}_2\text{O}_8$ ,  $4\text{NO}_3$ ,  $2\text{CO}_3$ ,  $2\text{CrO}_4$ ; the hydroxide,  $\text{X}_1 = (\text{OH})$ , is known in aqueous solution, it is fairly stable, and has a strongly alkaline reaction.

**V. LUTECHROMIUM SERIES**  $\text{Cr}_2 \cdot 12\text{NH}_4 \cdot \text{X}_1$ . **Luteochromium nitrate**,  $\text{Cr}_2 \cdot 12\text{NH}_4 \cdot (\text{NO}_3)_2$ . 80 g.  $\text{K}_2\text{Cr}_2\text{O}_7$  are reduced to  $\text{CrCl}_3$  by the method described under chloropurpureochromium chloride; the solution is forced by H pressure into a flask containing 700 g.  $\text{NH}_4\text{Cl}$  in 750 c.c.  $\text{NH}_4\text{Aq}$

(S.G. .91); the flask, which must be entirely filled with the liquid, is closed by a cork carrying an exit tube opening under water, and is surrounded by cold water; after about 24 hrs. evolution of  $\text{H}$  ceases; the liquid is poured off from ppd. luteo-chloride and  $\text{NH}_4\text{Cl}$ , and is ppd. by alcohol; the crude luteo-chloride is washed with alcohol, dried, dissolved in warm water, and the solution is filtered into  $\text{HNO}_3\text{Aq}$  (S.G. 1.39); the crystals of luteo-nitrate are washed with dilute  $\text{HNO}_3\text{Aq}$  (1 vol. conc.  $\text{HNO}_3\text{Aq}$  to 2 vols.  $\text{H}_2\text{O}$ ), and then with alcohol. The pp. of mixed  $\text{NH}_4\text{Cl}$  and luteo-chloride formed in the process may be dissolved by repeated treatment with  $\text{H}_2\text{O}$ , and luteo-nitrate obtained by ppn. with  $\text{HNO}_3\text{Aq}$ . Luteo-nitrate crystallises in orange-yellow, lustrous plates; S. (abt. 15°) 2.5; insol. alcohol; nearly insol. dilute  $\text{HNO}_3\text{Aq}$ .

The luteo-chromium salts form many double compounds with acid radicles, and also with some negative metallic radicles; the more important salts are:— $\text{X}_1 = 2\text{NO}_3$ ,  $2\text{SO}_4$ ,  $2\text{NO}_3$ ,  $2\text{PtCl}_4$ ,  $\text{Cl}_2$ ,  $\text{Br}_2$ ,  $\text{I}_2$ ,  $\text{Cl}_2$ ,  $\text{H}_2\text{PtCl}_6$ ,  $\text{Cl}_2$ ,  $2\text{PtCl}_4$ ,  $3\text{PtCl}_4$ ,  $3\text{PtBr}_4$ ,  $\text{I}_2$ ,  $2\text{SO}_4$ ,  $3\text{SO}_4$ ,  $2\text{SO}_4$ ,  $2\text{PtCl}_4$ ,  $3\text{CO}_3$ ,  $2\text{NaP}_2\text{O}_7$ ,  $\text{Fe}_2(\text{CN})_6$ ,  $\text{Co}_2(\text{CN})_{12}$ ,  $\text{Cr}_2(\text{CN})_{12}$  (Jørgensen, J. pr. [2] 30, 1).

#### VI. RHODOCHROMIUM SERIES

**Rhodo-chromium bromide**,  $\text{OH} \cdot \text{Cr}_2 \cdot 10\text{NH}_4 \cdot \text{X}_1$ .  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ , equal to 10 g.  $\text{Cr}_2\text{O}_3$ , is dissolved in 160 c.c. conc.  $\text{HBrAq}$ ; the green solution is poured on to Zn in a cylinder arranged with a reversed U-tube, &c., as described under purpureochloride; 30 c.c.  $\text{HBrAq}$  (1 vol. conc. solution + 1 vol.  $\text{H}_2\text{O}$ ) are added; when the liquid is blue (after about 10 min.) 30 c.c. of the same  $\text{HBrAq}$  are added, and the H pressure is caused to force the liquid into 150 g.  $\text{NH}_4\text{Br}$  in 750 c.c. conc.  $\text{NH}_4\text{Aq}$ ; the blue solution is oxidised by a stream of air, after all particles of Zn have been removed; the liquid is quickly decanted from the blue pp. (basic rhodo-bromide), which is treated with excess of  $\text{HBrAq}$  (1 vol. conc. solution + 3 vols.  $\text{H}_2\text{O}$ ), whereby red rhodo-bromide is formed; the salt is washed with dilute  $\text{HBrAq}$  and then with water, it is then dissolved in cold water and the liquid is poured into moderately dilute  $\text{HBrAq}$ ; the crystals which separate are washed with dilute  $\text{HBrAq}$  and then with alcohol, and are dried in the air. Dried for some days over  $\text{H}_2\text{SO}_4$ , they lose their  $\text{H}_2\text{O}$ . Rhodo-bromide is a pale carmine-red crystalline powder; slowly loses its  $\text{H}_2\text{O}$  over conc.  $\text{H}_2\text{SO}_4$ ; sl. sol. cold  $\text{H}_2\text{O}$ ; on warming, the solution goes blue-violet; on boiling,  $\text{NH}_3$  comes off, and  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  pps.; insol. dilute  $\text{HBrAq}$  and  $\text{NH}_4\text{BrAq}$ ; boiled with very dilute  $\text{HBrAq}$  it is changed to roseochromium bromide; boiled with conc.  $\text{HBrAq}$  it gives bromopurpureo-bromide; with  $\text{AgNO}_3$  all the Br is ppd.; dilute  $\text{NaOHAq}$  or  $\text{NH}_4\text{Aq}$  removes  $\frac{1}{2}$  Br, and a basic rhodo- salt remains; dilute acids form the respective rhodo-salts.

The chief rhodo- salts known are:— $\text{X}_1 = \text{Cl}$ ,  $\text{I}$ ,  $5\text{NO}_3$ ,  $2\frac{1}{2}\text{CO}_3$ ,  $2\frac{1}{2}\text{SO}_4$ ,  $2\frac{1}{2}\text{S}_2\text{O}_8$ ,  $\text{Cl}_2$ ,  $2\text{AuCl}_3$ ,  $\text{Cl}_2$ ,  $\text{PtCl}_4$ ,  $\text{Cl}_2$ ,  $2\text{PtCl}_4$ , and the basic salts:— $\text{X}_1 = \text{OHLBr}$ ,  $\text{OHLCl}$ ,  $\text{OHLI}$ ,  $\text{OHL}_2\text{SO}_4$  (Jørgensen, J. pr. [2] 25, 321).

#### VII. ERYTHROCHROMIUM SERIES

**Erythro-chromium nitrate**,  $\text{OH} \cdot \text{Cr}_2 \cdot 10\text{NH}_4 \cdot \text{X}_1$ .  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ . Rhodo-chloride is prepared by filtering a solution of rhodo-bromide

into  $\text{HClAq}$  (1 vol. conc. solution + 1 vol.  $\text{H}_2\text{O}$ ); it is washed with alcohol, 5 g. rhodo-chloride are dissolved in 50 c.c.  $\text{H}_2\text{O}$  + 35 c.c. dilute  $\text{NH}_4\text{Aq}$ ; when the blue solution has become red by standing in air 4-5 vols. of dilute  $\text{HNO}_3\text{Aq}$  are added; the pp. is repeatedly treated with dilute  $\text{HNO}_3\text{Aq}$ , dissolved in  $\text{H}_2\text{O}$ , reppd. by  $\text{HNO}_3\text{Aq}$ , washed with alcohol, and dried in the dark. Erythrochromium nitrate is a crimson powder composed of microscopic octahedra; it decomposes slowly even in the dark; when strongly heated N oxides are evolved and  $\text{Cr}_2\text{O}_3$  remains; fairly sol. cold water; insol. alcohol; aqueous solution decomposes when boiled with separation of  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ ; aqueous solution boiled with a few drops of  $\text{HNO}_3\text{Aq}$  gives roseochromium nitrate; solid erythronitrate boiled with dilute  $\text{HClAq}$  gives chlorpurpureo-chloride.

Other salts are obtained by the action of acids on the bromide or chloride; the principal are:  $-\text{X}_2 = \text{Br}_2, \text{Cl}_2, 2\text{I}_2\text{SO}_3$ ; and the basic salts  $\text{X}_2 = \text{OH} \cdot \text{Br}_2, \text{OH} \cdot \text{ANO}_2, \text{OH} \cdot 2\text{S}_2\text{O}_4$  (Jørgensen, *J. pr.* [2] 25, 398).

Chromium, arsenates of. — Existence uncertain (v. ARSENATES, under ARSENIC ACIDS OF; vol. i. p. 308).

Chromium, bromides of. — Two are known; as neither has been gasified the formulae  $\text{CrBr}_2$  and  $\text{CrBr}_3$  may or may not represent the composition of the gaseous molecules; judging from the analogy of  $\text{CrCl}_2$ , it is probable that the formulae  $\text{CrBr}_2$  and  $\text{CrBr}_3$  are molecular. These compounds resemble the chlorides (q. v.) in their properties.

I. CHROMIUM BROMIDE  $\text{CrBr}_2$  or  $\text{Cr}_2\text{Br}_4$ . Obtained as white crystals by heating  $\text{CrBr}_3$  in  $\text{H}_2$ , by leading  $\text{HBr}$  over heated  $\text{Cr}$ , or by the action of N saturated with  $\text{Br}$  vapour on  $\text{Cr}$  at a red heat (Moissan, *A. Ch.* [5] 25, 401). Unchanged in dry air, but oxidises in presence of traces of moisture; dissolves in  $\text{H}_2\text{O}$  forming blue liquid, which dissolves large quantities of violet  $\text{CrCl}_3$ .

II. CHROMIUM BROMIDE  $\text{CrBr}_3$  or  $\text{Cr}_2\text{Br}_6$ . Small cylinders formed of  $\text{Cr}_2\text{O}_3$ ,  $\text{C}$ , and starch paste, are dried and heated to redness in a covered crucible; they are then heated in a tube of hard glass in dry  $\text{Br}$  vapour; crystals of  $\text{CrBr}_3$  sublime, and some remain mixed with, but easily separable from,  $\text{Cr}_2\text{O}_3$ . Dark, metal-like, lustrous, hexagonal crystals; olive-green by transmitted light, slightly dichroic in red light (Wöhler, *A.* 111, 332). Heated in air  $\text{Cr}_2\text{O}_3$  is formed;  $\text{KOH Aq}$  or  $\text{NaOH Aq}$  decomposes  $\text{CrBr}_3$  into  $\text{Cr}_2\text{O}_3$  and  $\text{KBr Aq}$  or  $\text{NaBr Aq}$ . Insol. in  $\text{H}_2\text{O}$ , but dissolves in presence of a little  $\text{CrBr}_3$ . A green solution containing  $\text{CrBr}_3$  is obtained by the action of  $\text{HBr Aq}$  on  $\text{Cr}_2\text{O}_3 \cdot \text{H}_2\text{O}$ .

Chromium, chlorides of. — Two exist,  $\text{CrCl}_2$  and  $\text{CrCl}_3$ . Chromic chloride has been gasified (at  $1200^\circ\text{--}1500^\circ$ ) and the observed V.D. corresponds with the formula  $\text{CrCl}_3$ ; it is probable, but not certain, that the molecular formula of chromous chloride is  $\text{CrCl}_2$ .

$\text{CrCl}_2$ , like several other compounds of  $\text{Cr}$ , exists in two forms; one sol., the other insol. in  $\text{H}_2\text{O}$ .  $\text{CrCl}_2\text{Aq}$  is an energetic reducer. Solutions of  $\text{CrO}$  and  $\text{CrO}_2$  in cold conc.  $\text{HCl Aq}$  may contain  $\text{CrCl}_2$  and  $\text{CrCl}_3$  respectively; these solutions are brown, they evolve  $\text{Cl}$  when heated, and  $\text{CrCl}_3$  remains.

VOL. II.

I. CHROMOUS CHLORIDE  $\text{CrCl}_2$  or  $\text{Cr}_2\text{Cl}_4$ . Mol. w. unknown.

Formation. — 1. By the action of dry  $\text{HCl}$  on  $\text{Cr}$  at a red heat (Ufer, *A.* 112, 302; Moissan, *A. Ch.* [5] 25, 401). — 2. By heating  $\text{CrCl}_3$  with  $\text{NH}_4\text{Cl}$  to a very high temperature (Moissan, *l.c.*).

Preparation. — Violet, sublimed  $\text{CrCl}_3$  is heated in a stream of perfectly dry  $\text{H}_2$ , free from every trace of  $\text{O}$ , to a very low red heat; the reduction takes place very slowly, but the temperature must not be raised, else some  $\text{Cr}$  will be formed (Moberg, *J. pr.* 29, 175; 43, 125; 44, 322; Péligot, *A. Ch.* [3] 12, 523). The  $\text{H}$  used should be passed through a solution of  $\text{SnCl}_2$  in  $\text{KOH Aq}$ , then through conc.  $\text{H}_2\text{SO}_4$ , then over red hot  $\text{Cu}$ , and lastly through boiled  $\text{H}_2\text{SO}_4$  and over  $\text{CaCl}_2$ .

Properties. — White lustrous crystals; sol. in  $\text{H}_2\text{O}$ , with production of heat, forming a blue liquid, which rapidly absorbs  $\text{O}$  turning green. Péligot determined the quantity of  $\text{O}$  absorbed; it corresponded with formation of  $\text{Cr}_2\text{Cl}_3\text{O}$ . Loewel (*A. Ch.* [3] 40, 42), by the prolonged action of granulated  $\text{Zn}$  on a solution of  $\text{CrCl}_2 \cdot 6\text{H}_2\text{O}$  in 3-5 parts  $\text{H}_2\text{O}$  in a flask nearly filled with the  $\text{Zn}$ , obtained a colourless solution of  $\text{CrCl}_2$  (containing  $\text{Zn}$ ), which acted as a strong reducer; e.g.  $\text{K} \cdot \text{CrO}_4\text{Aq}$  was reduced to  $\text{CrO}$ ,  $\text{HgCl}_2\text{Aq}$  to  $\text{HgCl}$ ,  $\text{CuSO}_4\text{Aq}$  to  $\text{Cu}_2\text{Cl}_2$  and  $\text{Cu}_2\text{O}$ , and solutions of  $\text{Au}$  and  $\text{Sn}$  salts to  $\text{Au}$  and  $\text{Sn}$ .

Reactions. —  $\text{CrCl}_2\text{Aq}$  protected from air gives the following reactions: — 1. With *potash* or *soda*, brownish-yellow  $\text{CrO}_2\text{H}_2$ , which quickly becomes  $\text{CrO}_2\text{H}$ , with evolution of  $\text{H}_2$ . — 2. *Potassium sulphide* pps. black  $\text{Cr}_2\text{S}_3$ . — 3. *Sodium acetate* forms a red liquid from which red lustrous crystals of  $\text{Cr}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{H}_2\text{O}$  separate after a time.

Combinations. — 1. With *water*, to form  $2\text{CrCl}_2 \cdot 3\text{H}_2\text{O}$  (Moissan, *A. Ch.* [5] 25, 401). — 2. With dry *hydrochloric acid*, to form an easily decomposed compound  $6\text{CrCl}_2 \cdot 4\text{HCl} \cdot 26\text{H}_2\text{O}$  (Racour, *C. R.* 100, 1227).

II. CHROMIC CHLORIDE  $\text{CrCl}_3$ . Mol. w. 158.55. V.D. 77.45 (Scott, *Pr. E.* 14, 410).

Formation. — By heating  $\text{Cr}_2\text{S}_3$  in dry  $\text{Cl}$  (Berzelius, *P.* 50, 79; Brunner, *D. P. J.* 159, 356).

Preparation. — An intimate mixture of  $\text{Cr}_2\text{O}_3$  and lampblack is made into little pellets with starch paste; the pellets are dried and heated in a covered crucible, they are then placed in a Hessian crucible, through the bottom of which is fitted a porcelain tube about 6 inches long; the upper end of this tube, which passes a very little way into the crucible, is loosely covered with a very small crucible to prevent the pellets falling into the tube; into the mouth of the Hessian crucible is fitted a smaller crucible, inverted, and pierced by a hole. The crucibles are arranged in a furnace, so that the lower one may be heated very highly and the upper kept comparatively cool. The porcelain tube is connected with a supply of dry  $\text{Cl}$ . The pellets are now heated in a rapid stream of  $\text{Cl}$ ;  $\text{CrCl}_3$  sublimes into the upper crucible; the whole is allowed to cool in  $\text{Cl}$ , else  $\text{Cr}_2\text{O}_3$  may be formed. The sublimate is washed with cold  $\text{H}_2\text{O}$  to remove  $\text{AlCl}_3$  formed from the crucible (Wöhler, *A.* 111, 230; Ufer, *A.* 112, 281).

Properties. — Lustrous, peach-blossom coloured plates. S.G. 3.03 (Schafarik, *J. pr.* 90, 12). Decomposed at high temperature without fusion with evolution of  $\text{Cl}$  (Carnelley & Williams, *C. J.* 37, 126). Insol. in water, unacted on by

M

acids, even by *aqua regia*.  $\text{CrCl}_3$  may be obtained in soft violet-coloured plates, v. sol. in  $\text{H}_2\text{O}$ , by dissolving green  $\text{CrO}_3\cdot\text{H}_2\text{O}$  in  $\text{HClAq}$ , evaporating slowly until crystals of  $\text{CrCl}_3\cdot 6\text{H}_2\text{O}$  separate, and heating these in  $\text{HCl}$  or  $\text{Cl}$  not above  $250^\circ$  (Moberg, *J. pr.* 44, 325; Pélégot, *J. pr.* 37, 475).  $\text{CrCl}_3$  thus prepared dissolves very easily in  $\text{H}_2\text{O}$ , forming a green solution; heated above  $250^\circ$  the salt sublimes to crystals of the peach-blossom coloured, insoluble variety. The latter crystals when powdered and boiled with water for some time go into solution with production of a green liquid (Jacquelin, *C. R.* 21, 679).

A violet solution of  $\text{CrCl}_3$  is produced by decomposing violet  $\text{Cr}_2\text{SO}_4\text{Aq}$  by an equivalent quantity of  $\text{BaCl}_2\text{Aq}$ . When this solution is boiled it becomes green.

The green solutions evaporated at  $100^\circ$  give crystals of  $\text{CrCl}_3\cdot x\text{H}_2\text{O}$  (v. *Combinations*, No. 1); the same green hydrates of  $\text{CrCl}_3$  are obtained by dissolving green  $\text{CrO}_3\cdot\text{H}_2\text{O}$  in  $\text{HClAq}$ , or the insoluble  $\text{CrCl}_3$  in  $\text{H}_2\text{O}$  containing a trace of  $\text{CrCl}_3$ , or  $\text{PbCrO}_4$  in conc.  $\text{HClAq}$  and reducing by alcohol, and evaporating at about  $100^\circ$ ; evaporated at higher temperatures oxy-chlorides (q. v.) are obtained. These green solutions probably therefore contain  $\text{CrCl}_3$ . But only two-thirds of the total  $\text{Cl}$  is ppd. from them in the cold by  $\text{AgNO}_3\text{Aq}$ ; on boiling for some time the rest of the  $\text{Cl}$  also forms  $\text{AgCl}$ . On the other hand,  $\text{AgNO}_3\text{Aq}$  pps. all the  $\text{Cl}$  from the violet-coloured solution of  $\text{CrCl}_3$  obtained by the action of  $\text{BaCl}_2\text{Aq}$  on violet  $\text{Cr}_2\text{SO}_4\text{Aq}$ . Moreover, green-coloured double chlorides,  $\text{MCl}_2\text{CrCl}_3$ , where  $\text{M}$  = alkali metal, are not obtained, whereas several violet double chlorides are known (v. *Combinations*, No. 2). Pélégot (*J. pr.* 37, 475) supposed that a green solution of  $\text{CrCl}_3$  contains  $\text{CrOCl}$  and  $\text{HCl}$ ; Berzelius (*P.* 50, 79) supposed that on adding  $\text{AgNO}_3$ , a double compound of  $\text{AgCl}$  and  $\text{CrCl}_3$  is formed and that this is decomposed only on boiling.

**Reactions.**—1. Finely powdered  $\text{CrCl}_3$  boiled for some time with water slowly dissolves, forming a green solution (Jacquelin, *C. R.* 21, 679). If the water contains  $\frac{1}{100}$  to  $\frac{1}{1000}$  of its weight of  $\text{CrCl}_3$ , or a little  $\text{SnCl}_2$  or  $\text{Cu}_2\text{Cl}_2$ , the  $\text{CrCl}_3$  quickly dissolves with production of much heat, forming a green liquid with the same reactions as that obtained by dissolving  $\text{CrO}_3\cdot\text{H}_2\text{O}$  in  $\text{HClAq}$  (Pélégot, *J. pr.* 36, 150; Loewel, *J. pr.* 37, 150; Pelouze, *P.* 24, 233; Moberg, *A.* 109, 82; Barreswill, *A. Ch.* 12, 528) (v. *Combinations*, No. 1; also CHROMIUM, OXYCHLORIDES OF).—2. Boiled with potash or soda  $\text{CrCl}_3$  is slowly decomposed with formation of  $\text{Cr}_2\text{O}_3$ .—3. Fused with nitre and an alkali or alkaline carbonate chromate and chloride of the alkali metal are formed.—4. Molten potassium dichromate forms  $\text{CrO}_2\cdot\text{Cl}_2\cdot\text{OK}$  (Genthner, *A.* 118, 61).—5. Heated with chromic anhydride  $\text{Cr}_2\text{O}_3$  and  $\text{CrO}_2\text{Cl}_2$  are produced.—6. Heated in air  $\text{Cr}_2\text{O}_3$  results.—7. Heated in dry hydrogen  $\text{CrCl}_3$ , and then  $\text{Cr}$ , is formed.—8. Zinc or potassium reduces  $\text{CrCl}_3$  to  $\text{Cr}$  when heated with it.—9. Heated in ammonia  $\text{CrN}$  is formed.—10. Heated in phosphoretted hydrogen  $\text{CrP}$  results.—11. Heated in sulphuretted hydrogen or with sulphur the product is  $\text{Cr}_2\text{S}_3$ .

**Combinations.**—1. With water, to form various green, crystalline, easily soluble hydrates:— $2\text{CrCl}_3\cdot 9\text{H}_2\text{O}$ , by evaporating  $\text{CrO}_3\cdot\text{H}_2\text{O}$  in  $\text{HClAq}$

in dry air at  $100^\circ$  (Moberg, *J. pr.* 29, 175);  $\text{CrCl}_3\cdot 6\text{H}_2\text{O}$ , by evaporating (1) violet  $\text{CrCl}_3$  in  $\text{H}_2\text{O}$  containing a trace of  $\text{CrCl}_3$  in dry air, or (2) solution obtained by action of conc.  $\text{HClAq}$  and alcohol on  $\text{PbCrO}_4$  (Pélégot, *J. pr.* 37, 475; Moberg, *J. pr.* 44, 326). Godefroy (*Bl. [2]* 43, 229) describes also  $\text{CrCl}_3\cdot 10\text{H}_2\text{O}$ , and  $\text{CrCl}_3\cdot 4\text{H}_2\text{O}$ , as green crystals. One or other of these hydrates is probably formed when violet  $\text{CrCl}_3$  dissolves in  $\text{H}_2\text{O}$  containing a trace of  $\text{CrCl}_3$ ; Loewel (*J. pr.* 37, 150) supposes that the  $\text{CrCl}_3$  is reduced to  $\text{CrCl}_2$  by the action of the  $\text{CrCl}_3$  present, and that the  $\text{CrCl}_2$  thus formed combines with  $\text{H}_2\text{O}$  and dissolves as  $\text{CrCl}_2\cdot x\text{H}_2\text{O}$ , and that more  $\text{CrCl}_3$  is reduced by the freshly formed  $\text{CrCl}_2$ , and so on (v. also Recoura, *C. R.* 102, 921). According to Recoura (*C. R.* 102, 513 a. 548) the hydrate  $2\text{CrCl}_3\cdot 13\text{H}_2\text{O}$  exists in two varieties: (1) green crystals, produced by passing  $\text{HCl}$  into a saturated solution of green  $\text{CrCl}_3$  (or by passing air into cooled  $\text{CrCl}_3\text{Aq}$  containing much  $\text{HCl}$ , and then passing in  $\text{HCl}$ ; *C. R.* 102, 921); (2) greyish blue crystals, produced by heating a solution of 1 pt. of the green crystals in 1 pt. water, and then saturating with  $\text{HCl}$ . The green crystals dissolve in water ( $S. = 130$ ) without production of heat; the greyish blue crystals dissolve very readily in water with production of much heat [ $2\text{CrCl}_3\cdot 13\text{H}_2\text{O}, \text{Aq} = 24,000$ ].—2. With alkali chlorides to form double salts  $\text{MCl}_2\text{CrCl}_3$ , the properties of which are little known; prepared by treating  $\text{M}_2\text{Cr}_2\text{O}_7$  ( $\text{M} = \text{K}, \text{Na}$ , or  $\text{NH}_4$ ) with  $\text{HClAq}$  and alcohol, and evaporating at  $100^\circ$  until the residue is violet. On adding  $\text{H}_2\text{O}$  solution occurs, the liquid is yellow-red, but soon becomes green. Godefroy (*Bl. [2]* 42, 194) says that various double metallic chlorides containing  $\text{CrCl}_3$  may be obtained by passing  $\text{Cl}$  into a mixture of metallic chromate and alcohol, and washing the products with  $\text{HClAq}$ ; these double salts are decomposed by  $\text{H}_2\text{O}$ , but are unchanged in  $\text{HClAq}$  containing 32½ p.c.  $\text{HCl}$ .—3. With phosphoric chloride to form  $2\text{CrCl}_3\cdot 2\text{PCl}_5$ ; obtained by heating the constituent chlorides in a sealed tube, and then to  $140^\circ$ – $150^\circ$  in an open vessel (Cronander, *B.* 6, 1466).—4. With ammonia to form several compounds (v. CHROMIUM, AMMONIO-SALTS OF).

**Chromium, cyanides of, and their derivatives v. CYANIDES.**

**Chromium, fluorides of.** Only one is known with fair certainty.  $\text{CrF}_3$  is described by Deville (*C. R.* 43, 970) as forming lustrous, monometric, octahedra; obtained by dissolving dry  $\text{CrO}_3\cdot\text{H}_2\text{O}$ , which has not been strongly heated, in  $\text{HFAq}$ , evaporating in a Pt dish, and heating the green mass to a very high temperature. The double salts  $\text{CrF}_3\cdot 2\text{MF}_2\cdot \text{H}_2\text{O}$ , where  $\text{M} = \text{Na}, \text{K}$ , or  $\text{NH}_4$ , are described by Wagner (*B.* 19, 896).

Unverdorben (*P.* 7, 811) obtained a red gas by heating fluorspar and  $\text{PbCrO}_4$  with conc.  $\text{H}_2\text{SO}_4$ . Dumas (*A. Ch.* [2] 31, 435) prepared the compound as a deep red liquid, by warming 4 pts. dry  $\text{PbCrO}_4$ , 3 pts. dry pure  $\text{CaF}_2$ , and 5–7 pts. very conc.  $\text{H}_2\text{SO}_4$ , in a retort of Pt or Pb, and leading the gas through a well-cooled tube of Pt and Pb into a Pt receiver. The liquid is volatile; the vapour acts on the mucous membranes and produces violent coughing; it is at once decomposed in ordinary air, or by  $\text{H}_2\text{O}$ , to  $\text{HF}$  and  $\text{CrO}_3$ ; it acts rapidly on glass, forming  $\text{SiF}_4$ .

The formula  $\text{CrF}_3$  was given from estimations of the quantities of  $\text{CrO}_3$  and  $\text{HF}$  produced by leading the gas into water. Rose (*P.* 27, 565) found more  $\text{F}$  than agreed with  $\text{CrF}_3$ . Oliveri (*G.* 16, 218) recently examined this supposed fluoride according to him it is an oxyfluoride  $\text{CrO}_2\text{F}_2$ , analogous to  $\text{CrO}_2\text{Cl}_2$ .

Chromium, hydrated oxides of, v. CHROMIUM, HYDROXIDES OF.

**Chromium, hydroxides of.** Several compounds of  $\text{Cr}$  with  $\text{H}$  and  $\text{O}$  are known. They react rather as hydrated oxides than as hydroxides (v. *Art. HYDROXIDES*). Chromous hydroxide, or hydrated chromous oxide,  $\text{CrO}_2\text{H}_2(\text{CrO}_2\text{H}_2\text{O})$  is very easily oxidised; it behaves towards acids as a salt-forming compound. At least three hydrates of  $\text{Cr}_2\text{O}_3$  are known:—

and  $\text{Cr}_2\text{O}_3 \cdot \text{H}_2\text{O} (\text{Cr}_2\text{O}_3 \cdot \text{H}_2\text{O})$ ; these compounds are all salt-forming in their reactions with acids, but at the same time they exhibit feebly acidic functions. The hydrate  $\text{CrO}_2\text{H}_2\text{O} (\text{CrO}_2\text{H}_2\text{O})$  is a strongly marked acid.

The hydrates of  $\text{Cr}$  are more or less easily separated into oxide and  $\text{H}_2\text{O}$  by the action of heat; the oxide  $\text{Cr}_2\text{O}_3$  does not directly combine with water;  $\text{CrO}_2$  readily combines with  $\text{H}_2\text{O}$ , but the solution is separated into  $\text{CrO}_2$  and  $\text{H}_2\text{O}$  by boiling; the action of  $\text{CrO}$  towards  $\text{H}_2\text{O}$  is not known as the oxide has not been prepared.

**I. CHROMOUS HYDROXIDE.**  $\text{CrO}_2\text{H}_2$  or  $\text{CrO}_2\text{H}_2\text{O}$ . It is doubtful whether this compound has been obtained quite free from  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ . A solution of  $\text{CrCl}_3$  in air-free water, and protected from air, gives a yellowish-brown pp. with  $\text{KOH}$  dissolved in air-free  $\text{H}_2\text{O}$  (Moberg, *J. pr.* 43, 114 a. 125). The hydroxide quickly absorbs  $\text{O}$  and becomes dark brown; it rapidly decomposes  $\text{H}_2\text{O}$ , and combines with part of the  $\text{O}$  evolved.  $\text{CrO}_2\text{H}_2$  is slowly dissolved by acids with separation of  $\text{Cr}$  and formation of chromous salts  $\text{CrX}_2$ , e.g.  $\text{CrSO}_4 \cdot 7\text{H}_2\text{O}$ ,  $\text{Cr}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{H}_2\text{O}$ , &c.; these salts are unstable, and readily oxidise to chromic salts  $\text{CrX}_3$  (Moberg, *J. pr.* 41, 330; Péligot, *A.* 52, 247) (v. CHROMIUM, SALTS OF, p. 167).

**II. CHROMIC HYDROXIDES.** *Preparation.*—A clear blue pp. of  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  is obtained by the action of  $\text{NH}_4\text{Aq}$  on  $\text{CrCl}_3\text{Aq}$  at the ordinary temperature. The  $\text{CrCl}_3\text{Aq}$  must be perfectly free from any fixed alkali; it is prepared by dissolving  $\text{Cr}$  in  $\text{HClAq}$ , or  $\text{CrCl}_3$  in  $\text{H}_2\text{O}$  containing a trace of  $\text{CrCl}_3$ , or by reducing  $\text{CrO}_3$  by  $\text{HClAq}$ . When the pp. is thoroughly washed and dried over sulphuric acid the compound  $\text{Cr}_2\text{O}_3 \cdot 7\text{H}_2\text{O} (\text{Cr}_2\text{O}_3 \cdot \text{H}_2\text{O} \cdot 4\text{H}_2\text{O})$  is obtained; when dried in *vacuo*  $\text{Cr}_2\text{O}_3 \cdot 4\text{H}_2\text{O} (\text{Cr}_2\text{O}_3 \cdot \text{H}_2\text{O} \cdot \text{H}_2\text{O})$  remains; and when dried at  $200^\circ$ – $220^\circ$  in  $\text{H}_2\text{O}$  the compound  $\text{Cr}_2\text{O}_3 \cdot \text{H}_2\text{O} (\text{Cr}_2\text{O}_3 \cdot (\text{OH})_2)$  is produced (Siewert, *Z. f. d. ges. Naturwiss.* 18, 244).

For accounts of the earlier experiments on composition of the various  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  v. Lefort, *J. pr.* 51, 261; Hertwig, *A.* 45, 298; Schaffner, *A.* 51, 168; Fremy, *C. R.* 47, 883; Ordway, *Am. S.* [2] 26, 137; Mitscherlich, *Lehrb. d. Chem.* [4th ed.] 2, 751; Vincent, *P. M.* [4] 13, 191).

The pp. obtained by the action of  $\text{KOHAg}$  or  $\text{NaOHAg}$  on  $\text{CrCl}_3\text{Aq}$ , or on solutions of other chromic salts, contains alkali which cannot be removed by hot water.

Graham (*T.* 1861. 183), by long-continued dialysis of solution of freshly ppd.  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  in  $\text{CrCl}_3\text{Aq}$ , obtained a liquid containing 1.5 pts.  $\text{HCl}$  to 98.5  $\text{Cr}_2\text{O}_3 (= \text{HCl} : 31 : 2\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O})$ ; this solution, which may be taken as nearly pure  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  dissolved in water, was unchanged on dilution or boiling, but was coagulated by addition of traces of salts, with separation of  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ .

A green hydrate—approximately pure  $\text{Cr}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ —known as Guignet's green, is obtained by heating 10 pts.  $\text{K}_2\text{Cr}_2\text{O}_7$  and 18 pts. crystallised boric acid to low redness, and treating with  $\text{H}_2\text{O}$ . It is scarcely soluble in boiling  $\text{HClAq}$  (v. Scheurer-Kestner, *Bt.* 1865. 23; Salvéat, *C. R.* 48, 295).

**Properties and Reactions.**—Any of the hydrates  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  heated to  $200^\circ$  in air takes up  $\text{O}$ , forming a black powder, which reacts with  $\text{HClAq}$  evolving  $\text{Cl}$ , and from which  $\text{H}_2\text{O}$  dissolves out  $\text{CrO}_2$  (Siewert, *l.c.*; Krüger, *A.* 52, 249). The three hydrates where  $x=7, 4$ , or 1, are hygroscopic;  $\text{Cr}_2\text{O}_3 \cdot \text{H}_2\text{O}$  is insol. in boiling dilute  $\text{HClAq}$ , the two others dissolve in acids forming chromic salts,  $\text{CrX}_3$  (v. CHROMIUM, SALTS OF). The hydrates are sol. in  $\text{KOHAg}$ , but on standing or boiling they are reppd., and the pps. contain alkali; they are sl. sol. in  $\text{NH}_4\text{Aq}$ , but are reppd. on boiling.

The hydrates  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  react towards acids as salt-forming hydroxides; but they also exhibit slightly acidic functions. Thus, the pps. obtained by adding  $\text{KOHAg}$  to solutions of chromic salts cannot be washed free from alkali even by hot water. Also,  $\text{NH}_4\text{Aq}$  added to solution of a chromic salt mixed with a salt of  $\text{Ca}$  or  $\text{Zn}$ , &c., forms a pp. containing  $\text{Cr}_2\text{O}_3$  and  $\text{CaO}$  or  $\text{ZnO}$  &c. (Pelouze, *A. Ch.* [3] 33, 5). Solution of  $\text{PbO}$  or  $\text{ZnO}$  in  $\text{KOHAg}$ , mixed with solution of  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  in  $\text{KOHAg}$ , yields a pp. of  $\text{MO} \cdot \text{Cr}_2\text{O}_3$  (Chancel, *C. R.* 43, 927). By long digestion of  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  in conc.  $\text{NH}_4\text{Aq}$  a dark-blue compound of  $\text{Cr}_2\text{O}_3$  with  $\text{NH}_3$  is produced, insol. in water, but sol. in  $\text{HClAq}$  (v. CHROMITES; and CHROMIUM, AMMONIO-SALTS OF).

**Chromium, iodides of.** Very little is known regarding these compounds. None seems to have been definitely isolated (v. Walz, *C. N.* 26, 245). Moissan (*A. Ch.* [5] 25, 401) describes  $\text{CrI}_3$ , or  $\text{Cr}_2\text{I}_6$ , as a white salt sol. in water with formation of blue liquid; obtained by the action of  $\text{HI}$ , or  $\text{I}$  vapour, on heated  $\text{Cr}$ .

**Chromium, nitride of.**  $\text{CrN}$ . Mol. w. unknown.

**Preparation.**—1. Finely powdered  $\text{Cr}$  is heated to whiteness in  $\text{N}$ ; the metal is again powdered and heated in  $\text{N}$ , and this process is repeated several times. Unchanged  $\text{Cr}$  is dissolved out by conc.  $\text{HClAq}$  (Briegleb, *A.* Gauthier, *A.* 123, 228).—2.  $\text{CrCl}_3$  dried at about  $120^\circ$  is strongly heated in dry  $\text{NH}_3$ , the process being repeated several times; the residual  $\text{CrCl}_3$  is removed by long digestion in conc.  $\text{HClAq}$  in contact with  $\text{Sn}$  ( $\text{CrCl}_3$  is formed and dissolved); the product is washed, and dried at  $100^\circ$ – $120^\circ$  (Ufer, *A.* 112, 281; v. also Liebig, *P.* 21, 859; Schrötter, *A.* 87, 148; Gmelin, *Gm.* 4, 139).

**Properties and Reactions.**—Heavy, black, amorphous powder. Heated to about  $1600^\circ$  in absence of air, it is decomposed to  $\text{Cr}$  and  $\text{N}$  (Ufer, *A.* 112, 281). It is unacted on by  $\text{KOHAg}$ .

by dilute acids, by conc.  $\text{HClAq}$  or  $\text{HNO}_3$ , by  $\text{H}_2$ , by steam, or by molten  $\text{Na}_2\text{CO}_3$ ; *aqua regia* dissolves it slowly; cold conc.  $\text{H}_2\text{SO}_4$  dissolves it with formation of  $\text{Cr}_2(\text{NH})_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$ , and without evolution of  $\text{N}$ . Heated in  $\text{HCl}$  gas,  $\text{CrCl}_3$  and  $\text{NH}_4\text{Cl}$  are formed. Slowly sol. in solutions of alkaline hypochlorites, with formation of alkaline chromates and  $\text{N}$ ; decomposed by molten  $\text{KNO}_3$ , or  $\text{KClO}_3$ , with formation of  $\text{K}_2\text{CrO}_4$  and  $\text{N}$  (Ufer, *l.c.*); decomposes  $\text{NH}_4$ , to  $\text{N}$  and  $\text{H}$  at red heat; unacted on by  $\text{Cl}$  in the cold, but when heated slight explosions occur, and  $\text{CrCl}_3$  and  $\text{N}$  are produced.

**Chromium, oxides of.** Three oxides of  $\text{Cr}$  are known,  $\text{Cr}_2\text{O}_3$ ,  $\text{CrO}_2$ , and  $\text{CrO}$ ;  $\text{Cr}_2\text{O}_3$ ,  $\text{CrO}_2$ , and perhaps an oxide higher than  $\text{CrO}_2$ , probably exist.  $\text{Cr}_2\text{O}_3$  acts as a salt forming oxide towards acids, and also shows feebly acidic properties;  $\text{CrO}_2$  is distinctly an anhydride, it reacts with water to form the acid  $\text{H}_2\text{CrO}_4$ ; with acids it forms chromic salts,  $\text{CrX}_3$ , and  $\text{O}$ ; no salts corresponding to  $\text{CrO}_2$  have been prepared, this oxide is said to evolve  $\text{Cl}$  by the action of  $\text{HClAq}$ . Chromous oxide,  $\text{CrO}$ , is not known, but approximately pure  $\text{CrO} \cdot \text{H}_2\text{O}$  (v. CHROMIUM, HYDROXIDES or) has been prepared.  $\text{CrO}$  is said to combine directly with  $\text{O}$  to form  $\text{CrO}_2$ ; it is readily oxidised in presence of alkali to chromate  $\text{M}_2\text{CrO}_4$ , from which  $\text{CrO}_2$  is obtained.  $\text{Cr}_2\text{O}_3$  and  $\text{CrO}_2$ , if they exist, may be regarded as  $\text{CrO} \cdot \text{Cr}_2\text{O}_3$  and  $2\text{CrO} \cdot \text{Cr}_2\text{O}_3$ , respectively;  $\text{CrO}_2$  is sometimes regarded as  $\text{Cr}_2\text{O} \cdot \text{Cr}_2\text{O}_3$  (v. CHROMIUM, ACIDS or).

**I. CHROMIC OXIDE  $\text{Cr}_2\text{O}_3$  (green oxide of chromium).** Mol. w. unknown as compound has not been gasified. S.G. 4.91 to 5.01 (Playfair a. Joule, *C. S. Mem.* 3, 57; Schröder, *P.* 106, 226). Schiff (*A.* 106, 114) gives S.G. 6.2 for crystallised  $\text{Cr}_2\text{O}_3$ . Crystallises in hexagonal forms;  $\alpha$  = 1:1:3682. S.L. ( $21^\circ$ – $62^\circ$ )  $\cdot 177$  (Kopp, *T.* 165, 71).

**Occurrence.**—As chrome-ochre; in combination with  $\text{FeO}$  in chrome-ironstone.

**Formation.**—1. By heating chromic hydroxide (*q. v.*).—2. By heating finely divided  $\text{Cr}$  in  $\text{O}$ .—3. By heating  $\text{CrO}_2$ .—4. By heating  $(\text{NH}_4)_2\text{Cr}_2\text{O}_7$  or  $\text{Hg}_2\text{CrO}_4$ .—5. By heating  $\text{CrCl}_3$  in air.

**Preparation.**—1. A mixture of 5 pts. finely powdered, dry,  $\text{K}_2\text{Cr}_2\text{O}_7$ , and 1 pt.  $\text{S}$ , is heated to redness in a crucible, and the product is washed with  $\text{H}_2\text{O}$  until all  $\text{K}_2\text{SO}_4$  and  $\text{K}_2\text{S}$  are dissolved out (Lassaigne, *A. Ch.* [3] 14, 299; Dietrich, *W. J.* 1866, 273).—2. Equal parts of dry, powdered,  $\text{K}_2\text{Cr}_2\text{O}_7$ , and  $\text{NH}_4\text{Cl}$  are mixed with a little  $\text{Na}_2\text{CO}_3$ , strongly heated so long as any gas ( $\text{N}$ ) comes off, and the residue is washed free from  $\text{KCl}$  (Wöhler, *P.* 10, 46; Böttger, *A.* 47, 339).—3. Crystalline  $\text{Cr}_2\text{O}_3$  may be prepared by passing vapour of  $\text{CrOCl}_2$  through a glass tube heated to low redness (Wöhler, *P.* 33, 341); or by heating to bright redness, in a Hessian crucible, a mixture of equal parts of dry, powdered,  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{NaCl}$ , covered with a layer of  $\text{NaCl}$ , and washing the residue free from  $\text{KCl}$  and  $\text{NaCl}$  (Schiff, *A.* 106, 114; 108, 30). The crystalline oxide is also obtained by strongly heating the amorphous oxide in  $\text{O}$  (Sidot, *C. R.* 69, 201); or by fusing the amorphous oxide with  $\text{CaCO}_3$  and  $\text{B}_2\text{O}_3$  (Ebelmen, *A. Ch.* [5] 22, 211). Blake (*Am. S.* [2] 10, 352) found crystalline  $\text{Cr}_2\text{O}_3$  in a furnace used for making  $\text{K}_2\text{CrO}_4$  from chrome-

ironstone. (For other methods of preparing amorphous  $\text{Cr}_2\text{O}_3$ , v. Barian, *A.* 40, 203; Berthier, *A. Ch.* [2] 17, 56; Böttger, *J. pr.* 103, 314. For other methods of preparing crystalline  $\text{Cr}_2\text{O}_3$ , v. Gentile, *J. pr.* 54, 187; Fremy, *A.* 49, 274; Müller, *P.* 127, 404; Otto, *A.* 142, 102.)

**Properties and Reactions.**—Amorphous  $\text{Cr}_2\text{O}_3$  is a green powder, more or less dark, according to the method of preparation. Crystalline  $\text{Cr}_2\text{O}_3$  forms very dark green, lustrous, hexagonal crystals; as hard as corundum; isomorphous with  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$ .  $\text{Cr}_2\text{O}_3$ , which has been strongly heated, or crystalline  $\text{Cr}_2\text{O}_3$ , is insol. acids; fused with  $\text{KNO}_3$ , or  $\text{KHSO}_4$ ,  $\text{K}_2\text{CrO}_4$  is formed and dissolves in  $\text{H}_2\text{O}$ . Amorphous  $\text{Cr}_2\text{O}_3$ , if not strongly heated, dissolves in most acids to form chromic salts  $\text{CrX}_3$ .  $\text{Cr}_2\text{O}_3$  is not reduced by  $\text{H}_2$ , and by  $\text{C}$  only when intimately mixed and strongly heated. Heated in  $\text{Cl}$ ,  $\text{CrO}_2\text{Cl}_2$  is formed; if the oxide is perfectly dry, a little  $\text{CrCl}_3$  is produced (Moissan, *Bl.* [2] 34, 70); heated to about  $110^\circ$  in air,  $\text{CrO}_2$  is produced (Moissan, *l.c.*); heated in  $\text{H}_2\text{S}$ ,  $\text{Cr}_2\text{S}_3$  results (Moissan, *l.c.*).

**Combinations.**—1. With water, indirectly, to form  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ .—2. With several metallic oxides to form compounds  $\text{MO} \cdot \text{Cr}_2\text{O}_3$ ; v. CHROMITES; under CHROMIUM, ACIDS or, p. 158.

**II. CHROMIUM DIOXIDE  $\text{CrO}_2$  (Chromium tetroxide. Brown oxide of chromium. Chromate of chromium.)** Mol. w. unknown. This oxide is a product (1) of the oxidation of  $\text{Cr}_2\text{O}_3$ , (2) of the reduction of  $\text{CrO}_3$ .

**Formation.**—1. By heating  $\text{Cr}_2\text{O}_3$  in air, or  $\text{O}$ , to about  $400^\circ$  (Moissan, *A. Ch.* [5] 21, 243).—2. By heating  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  in air to about  $250^\circ$  (Kruger, *P.* 61, 219).—3. By the action of conc.  $\text{Cr}_2\text{SO}_4\text{Aq}$ , or  $\text{CrCl}_3\text{Aq}$ , on  $\text{K}_2\text{CrO}_4\text{Aq}$  ( $2\text{K}_2\text{CrO}_4\text{Aq} + \text{Cr}_2\text{SO}_4\text{Aq} + 3\text{CrO}_2$ ) (Maus, *P.* 9, 127; Bensch, *P.* 55, 98).—4. By the action of  $\text{Na}_2\text{S}_2\text{O}_4\text{Aq}$  on  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$

( $2\text{K}_2\text{Cr}_2\text{O}_7\text{Aq} + \text{Na}_2\text{S}_2\text{O}_4\text{Aq} = \text{K}_2\text{Cr}_2\text{O}_7\text{Aq} + \text{K}_2\text{SO}_4\text{Aq} + \text{Na}_2\text{SO}_4\text{Aq} + 3\text{CrO}_2$ ) (Popp, *A.* 156, 90). (For other methods v. Kopp, *C. N.* 11, 16; Vogel, *J. pr.* 77, 482; Siewert, *Z. f. d. ges. Naturwiss.* 13, 285; Schiff, *A.* 120, 207; Traube, *A.* 66, 106; Rammelsberg, *A.* 60, 203; Braun, *J. pr.* 90, 356; Oppenheim, *Bl.* [3] 1, 165).

**Preparation.**— $\text{NO}$  is passed into warm dilute  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$ ;  $\text{CrO}_2$  is slowly ppd.; the solution must not become concentrated ( $2\text{K}_2\text{Cr}_2\text{O}_7\text{Aq} + 2\text{NO} = 2\text{KNO}_3\text{Aq} + \text{K}_2\text{Cr}_2\text{O}_7\text{Aq} + 3\text{CrO}_2$ ). The pp. is washed with  $\text{H}_2\text{O}$ , then with alcohol, and dried at  $250^\circ$  for a long time until the weight is constant (Schweizer, *J. pr.* 39, 269; Hintz, *A.* 169, 367).

**Properties and Reactions.**—Dark grey, almost black, powder; very hygroscopic. Loses  $\text{O}$  at  $300^\circ$ ; heated in  $\text{Cl}$  to  $250^\circ$  a little  $\text{Cr}_2\text{O}_3\text{Cl}_2$  is formed; heated with  $\text{HClAq}$ , or with mixture of  $\text{HClAq}$  and  $\text{H}_2\text{SO}_4\text{Aq}$ , evolves  $\text{Cl}$  (Moissan, *A. Ch.* [5] 21, 243); heated with  $\text{KOH Aq}$ , out of contact with air, forms  $\text{K}_2\text{CrO}_4\text{Aq}$  and  $\text{CrO}_2$  (Moissan, *l.c.*); not acted on by  $\text{PCl}_5$  (Hintz, *A.* 169, 367).

**III. CHROMIUM TRIOXIDE  $\text{CrO}_3$  (Chromic anhydride. Red oxide of chromium.)** Mol. w. unknown. S.G. 2.67–2.82 (Playfair a. Joule, *C. S. Mem.* 3, 57; Schafarik, *Sitz. W.* 47 [2nd

part], 256). Crystallises in trimetric prisms;  $a:b:c = .7246:1: .6285$ . [About 190°] (Zettnow, P. 143, 468). S. (26°) 165 (Zettnow, l.c.).

**Occurrence.**—In combination with PbO, CuO, &c., in a few minerals.

**Formation.**—Chromates,  $M_2CrO_4$ , are produced by heating  $Cr_2O_3$  with alkaline oxidisers, e.g. KOH,  $KNO_3$ ,  $KClO_3$ ; or by the action of oxidisers—e.g. Cl,  $K_2MnO_4$ , Aq—on  $Cr_2O_3$ ,  $2H_2O$  in KOH aq.  $CrO_3$  is obtained from chromates by the action of strong acids.

**Preparation.**—400 grams commercial  $K_2Cr_2O_7$  are warmed with 500 c.c.  $H_2O$  and 420 c.c. conc.  $H_2SO_4$  until dissolved; after 10–12 hours the mother liquor is poured off from the crystals of  $KHSO_4$ ; the solution is kept at 80°–90°, 150 c.c. conc.  $H_2SO_4$  are added, and then  $H_2O$  drop by drop till the pp. of  $CrO_3$  has just dissolved; the liquid is evaporated until crystallisation begins. After 10–12 hours the liquid is separated from crystals of  $CrO_3$  by pouring through a funnel in which is placed a little filter of thin Pt pierced with small holes. The mother liquor yields a second and third crop of  $CrO_3$  crystals, by evaporation. The crystals of  $CrO_3$  are spread out on a porous plate, after 24 hours they are removed, 50 c.c. pure  $HNO_3$  aq. (S.G. 1.46) are added, and the whole is placed on another porous plate; if after 12 hours the  $CrO_3$  still gives reactions for  $H_2SO_4$  and K, 25 c.c.  $HNO_3$  aq. are added and exposure on a porous plate is repeated. The  $HNO_3$  is now removed by warming the crystals in a basin, at first very slightly, then to a rather higher temperature (60°–80°), until the crystals appear perfectly dry and fumes of  $HNO_3$  are no longer evolved. About 84 p.c. of pure  $CrO_3$  is obtained (Zettnow, P. 143, 468; modification of methods of Bolley, A. 56, 113, and Bunsen, A. 148, 289).  $CrO_3$  may also be prepared from  $PbCrO_4$  by the action of conc.  $H_2SO_4$  (Schrotter, P. 59, 616); or by the action of  $HNO_3$  aq. (Duvillier, C. R. 75, 711); also from  $BaCrO_4$  (Duvillier, l.c.); also by the action of moisture on a fluoride of Cr (? oxyfluoride; v. CHROMIUM FLUORIDES, p. 163) obtained by decomposing  $PbCrO_4$  and  $CaF_2$  by conc.  $H_2SO_4$  (Unverdorben, N. J. P. 9, 26; Berzelius, *Lehrbuch* [5th ed.], 2, 319).

**Properties.**—Carminc-red, very lustrous, trimetric prisms (Nordenskjöld, P. 114, 612); or loose, red, flakes. When melted at about 190° and solidified, appears as very dark red, metallic, crystalline mass. Very sol. in  $H_2O$ ; [ $CrO_3$ , Aq] = 1,900 (Sabatier, C. R. 103, 267); S.G. of solution containing x p.c.  $CrO_3$ , at temperature  $t$  (Zettnow, P. 148, 474):—

x.	t.	S.G.
8.25	16°	1.0606
12.34	19.5	1.0957
19.33	19	1.1569
31.83	20.1	1.2026
37.77	22	1.3441
62.23	22	1.7028

Sol. in pure ether and in cold dilute alcohol (Zettnow, l.c.). Solution in water is acid and reacts with metallic oxides, &c., to form salts  $M_2CrO_4$  (v. CHROMIUM ACID).  $CrO_3$  is easily decomposed; by action of acids it yields chromic salts  $CrX_3$ , and gives up O.

**Reactions.**— $CrO_3$  is very easily reduced. 1.  $CrO_3$  aq. is reduced by hydrogen (Ludwig, A.

162, 47).—2. Amorphous phosphorus heated to 200° forms  $CrO_3$ ; P dissolves in  $CrO_3$  aq. forming an acid phosphate of Cr (Oppenheim, Bl. [2] 1, 165).—3. Potassium or sodium reduces  $CrO_3$  on heating, probably to Cr.—4. Sulphur forms  $Cr_2S_3$  and  $SO_2$  (Moissan, A. Ch. [6] 5, 568).—5. Heated with sulphydric acid,  $Cr_2S_3$ ,  $H_2O$ , and S are formed (Hartew, A. 37, 350).—6. With haloid aqueous acids, halogen is evolved and  $CrX_3$  formed.—7. Sulphurous anhydride has no action at 100°; at 180°  $CrO_3$  and  $SO_2$  are formed (Traube, A. 66, 103);  $SO_3$  aq. and  $CrO_3$  aq. form at first  $H_2SO_4$  aq. and  $CrO_3$ , and then  $Cr_2(SO_4)_3$  aq. 8. Nitric oxide reduces  $CrO_3$  to  $Cr_2O_3$  (Reinsch, J. pr. 28, 391; Wöhler, A. 34, 236).—9. Arsenious oxide forms  $Cr_2O_3$  and  $H_2AsO_4$  aq. with  $CrO_3$  aq.—10. Ammonia forms  $Cr_2O_3$ ,  $H_2O$ , and N; light is produced.—11. Phosphoric chloride forms  $CrO_3$ ,  $Cl_2$ , and  $POCl_3$  (Schiff, A. 106, 116).—12. Ferric chloride heated with  $CrO_3$  forms  $Fe_2O_3$  and  $CrO_3$ ,  $Cl_2$  (Geuther, A. 106, 239).—13. Heated with violet chromic chloride  $CrO_2Cl_2$  and  $Cr_2O_3$  are formed (Geuther, A. 118, 69).—14.  $CrO_3$  aq. is reduced to  $Cr_2O_3$  by stannous chloride,  $SnCl_2$ , and  $SnO$ , being formed.—15. Cold conc. sulphuric acid dissolves  $CrO_3$  (it is said to be quite insoluble in very conc. acid with 16–17 p.c.  $H_2O$  added); a compound  $CrO_3.H_2SO_4$  is probably formed (v. Combinations, No. 2), but on heating,  $Cr_2(SO_4)_3$  or a basic Cr sulphate ( $4CrO_3.6SO_3.7H_2SO_4$ , according to Cross, A. Higgins, C. J. 41, 113), is formed, with evolution of O.—16.  $CrO_3$  aq. is reduced by electrolysis to Cr,  $Cr_2O_3$ , and O; 30,225 gram-units of heat are produced (Favre, C. R. 73, 890, A. 936; Geuther, A. 99, 314; Buff, A. 110, 257).—17. Iodine dissolves in conc.  $CrO_3$  aq.; the products are uncertain (Walz, C. N. 26, 245).—18. Oxygen, ozone, or pure dry chlorine, has no action on  $CrO_3$  (Moissan, A. Ch. [6] 5, 568).—19. Heated with carbon disulphide to 180° a little  $CO_2$  is formed (Armstrong, B. 2, 713).—20. Very many carbon compounds, e.g.  $C_2H_4$ ,  $C_2H_2$ ,  $C_2H_6$ ,  $C_2H_4O$ ,  $C_2H_5O$ ,  $C_2H_5CH_3$ , &c., are oxidised by  $CrO_3$  aq.; a mixture of  $K_2Cr_2O_7$ ,  $H_2SO_4$ , and  $H_2O$  is generally employed.

**Combinations.**—1. With water to form  $H_2CrO_4$  (Moissan, A. Ch. [6] 5, 568; v. CHROMIC ACID, under CHROMIUM ACIDS, &c.).—2. According to Bolley (A. 56, 113)  $CrO_3$  combines with sulphuric acid to form  $CrO_3.H_2SO_4$  (?  $H_2CrSO_4$ ); it is prepared by adding crystallised  $CrO_3$  to conc.  $H_2SO_4$ , little by little, until no more is dissolved, and after some days collecting the brown solid matter and drying on a porous plate. 3. Schröder describes a compound with sulphuric anhydride  $CrO_3.3SO_3$  (P. 59, 616; v. also Gay-Lussac, S. 32, 447; Fritzsche, J. pr. 27, 252). 4. Moissan (C. R. 97, 96) says that the body produced by the action of  $H_2O$  aq. on  $CrO_3$  aq., usually regarded as a higher oxide than  $Cr_2O_3$ , is really a compound of  $CrO_3$  and  $H_2O$ , viz.  $CrO_3.H_2O$  (v. *infra*).

#### IV. OTHER OXIDES OF CHROMIUM.

(i) The oxide  $Cr_2O_4$ ,—corresponding to  $Fe_2O_4$ ,  $Ni_2O_4$ , and  $Co_2O_4$ ,—is said to be produced by the action of air-free KOH aq. on  $CrCl_3$  aq., immediate washing the pp. with boiling water and drying *in vacuo*; it is scarcely soluble in acids; when heated it takes up O forming  $Cr_2O_3$  (Péligot, A. Ch. [3] 12, 539). By electrolysis  $CrCl_3$  aq.

containing  $\text{CrCl}_3$ , under special conditions, Bunsen obtained a black, amorphous, powder, insol. acids, oxidised by heating in air to  $\text{Cr}_2\text{O}_3$  (P. 91, 619). This powder seems to have been either a mixture or a compound of  $\text{CrO}$  and  $\text{Cr}_2\text{O}_3$  (but v. Geuther, A. 118, 66).

(ii) When  $\text{CrO}_3$  is heated in air, or  $\text{O}_2$ , to a little over  $200^\circ$  (Geuther a. Merz, A. 118, 62), or when a rapid stream of  $\text{CrO}_2\text{Cl}_2$  vapour is passed through a tube heated to above  $200^\circ$ , but not to redness (Wöhler, A. 111, 117), small, lustrous, dark-violet, trimetric prisms, S.G. about 4, are obtained. According to Wöhler the composition is  $\text{Cr}_2\text{O}_3$ ; according to Geuther  $\text{Cr}_2\text{O}_5$ . These crystals are distinctly magnetic, but lose their magnetism by heating in air; when strongly heated  $\text{Cr}_2\text{O}_3$  is formed. Insoluble in all acids including *aqua regia*; slowly acted on by conc. boiling  $\text{KOH}$ ; decomposed by molten  $\text{KOH}$  to  $\text{Cr}_2\text{O}_3$  and  $\text{K}_2\text{CrO}_4$ .

Traube (A. 66, 108) describes two oxides  $\text{Cr}_2\text{O}_{11}$  and  $\text{Cr}_2\text{O}_{12}$ ; but the existence of these as definite compounds is doubtful.

(iii) When  $\text{H}_2\text{O}_2\text{Aq}$  is added to  $\text{CrO}_3\text{Aq}$ , or when a dilute, strongly acid, solution of  $\text{BaO}_2$  in  $\text{HClAq}$  is added to  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$ , a deep-blue colour is produced in the solution (Barreswill, A. Ch. [3] 20, 364); this colour quickly disappears,  $\text{O}$  being evolved (Schönbein, P. 108, 471). The blue compound is more stable in ethereal than aqueous solution.  $\text{BaO}_2$  is added to  $\text{HClAq}$ , ether (free from alcohol) is then added, and then  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$  drop by drop with constant shaking; the ether becomes deep azure blue, it is free from  $\text{HCl}$  and  $\text{H}_2\text{SO}_4$ . The ethereal solution evolves  $\text{O}$  when evaporated, and  $\text{CrO}_3$  remains (Aschoff, J. pr. 81, 401 a. 487). Ferrous salts are oxidised by the blue ethereal liquid; alkalis decompose it to alkali chromates and  $\text{O}$ ; it is also decomposed by  $\text{Fe}_2\text{O}_3$ ,  $\text{CaCl}_2$ ,  $\text{MnO}_2$ ,  $\text{PbO}_2$ ,  $\text{HgO}$ ,  $\text{Na}$ , and by acids and bases (Moissan, C. R. 97, 96; v. also Martinon, B. [2] 45, 862). Certain alkaloids, e.g. strychnine and quinine, seem to form compounds with the blue-coloured body; these compounds are, however, unstable. According to Aschoff (J. pr. 81, 401 a. 471), for the formation and complete decomposition of the blue-coloured compound  $\text{H}_2\text{O}_2$  reacts with  $\text{K}_2\text{Cr}_2\text{O}_7$  in the ratio  $5\text{H}_2\text{O}_2 : \text{K}_2\text{Cr}_2\text{O}_7$ ; assuming the blue compound to be an oxide of  $\text{Cr}$  with the composition  $\text{Cr}_2\text{O}_5$ , the reaction in question might be represented as  
(1)  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq} + \text{H}_2\text{O}_2\text{Aq} + 2\text{HClAq} = 2\text{KClAq} + 2\text{H}_2\text{O} + \text{Cr}_2\text{O}_5\text{Aq}$ ;  
(2)  $\text{Cr}_2\text{O}_5\text{Aq} + 6\text{HClAq} + 4\text{H}_2\text{O} = \text{Cr}_2\text{Cl}_2\text{Aq} + 7\text{H}_2\text{O} + 8\text{O}$ . Fairley (C. N. 33, 237) supposes that the blue compound is  $\text{CrO}_3 \cdot 3\text{H}_2\text{O}$ . Moissan (C. R. 97, 96) obtained an ethereal solution of the dark-blue compound containing 5 p.c.  $\text{Cr}$ ; at  $-20^\circ$  in *vacuo* deep indigo blue, oily, drops were produced; by the action of  $\text{Na}$ ,  $\text{H}$  was evolved, and by gently warming  $\text{O}$  was evolved; the volumes of these gases obtained corresponded with those required by the formula  $\text{CrO}_3 \cdot \text{H}_2\text{O}$ . The blue compound cannot be obtained by the action of ozone on  $\text{CrO}_3\text{Aq}$ ; it is formed during electrolysis only when  $\text{H}_2\text{O}_2$  is also produced (Moissan, l.c.).

**Chromium, oxychlorides of.** Various oxychlorides, or perhaps compounds of  $\text{Cr}_2\text{O}_3$  and  $\text{CrCl}_3$ , are obtained by evaporating  $\text{CrCl}_3\text{Aq}$  at different temperatures (p. 167). Of the compounds

theoretically derivable from  $\text{CrO}_3(\text{OH})_3$ , by replacing  $\text{OH}$  by  $\text{Cl}$ , viz.  $\text{CrO}_3\text{OHCl}$  and  $\text{CrO}_2\text{Cl}_2$ , the second only is known; the first would react as an acid, the  $\text{K}$  salt of this acid is known (v. *Chlorochromates* under **CHROMIUM, ACIDS OF**, p. 157).  $\text{CrO}_2\text{Cl}_2$  easily parts with  $\text{O}$  and  $\text{Cl}$ ; heated in a closed tube  $\text{Cr}_2\text{O}_3\text{Cl}_2$  is produced.

I. **CHROMYL CHLORIDE**  $\text{CrO}_2\text{Cl}_2$  (*Chlorochromic acid. Chlorochromic anhydride*). Mol. w. 155.06. ( $115.9^\circ$ ) (Thorpe, C. J. 37, 362). S.G. ? 1.9617 (Thorpe, l.c.). V.D. 78.

**Formation.**—1. Equal parts  $\text{CrO}_3$  and  $\text{FeCl}_3$  are heated together in a retort (Geuther, A. 106, 239).—2.  $\text{CrO}_3$  and  $\text{CrCl}_3$  are heated together in the ratio  $2\text{CrCl}_3 : 3\text{CrO}_3$  (Geuther, A. 118, 69).—3. 1 part  $\text{CrO}_3$  and 2 parts  $\text{PCl}_5$  are heated together (Schiff, A. 106, 116).—4.  $\text{HCl}$  is passed into conc.  $\text{H}_2\text{SO}_4$  containing  $\text{CrO}_3$  in suspension (B. 10, 1041).—5.  $\text{HCl}$  is passed over  $\text{CrO}_3$  (Moissan, A. Ch. [6] 5, 568).

**Preparation.**—10 parts  $\text{NaCl}$  are fused with  $12\frac{1}{2}$  parts  $\text{K}_2\text{Cr}_2\text{O}_7$ ; the fused mass in fair-sized pieces is placed in a retort connected with a well-cooled condenser, and 25 parts fuming  $\text{H}_2\text{SO}_4$  are added. The reaction proceeds without heating (Thomson, T. 1827, 159; Berzelius, B. J. 6, 131; Wöhler, P. 33, 343; Etard, A. Ch. [5] 22, 218). About 70 p.c. of the theoretical yield of  $\text{CrO}_2\text{Cl}_2$  is obtained; part of the  $\text{CrO}_2\text{Cl}_2$  is decomposed by the acid to  $\text{CrO}_3$ ,  $\text{Cl}$ , and  $\text{Cr}_2\text{SO}_4$  (Etard, l.c.). The distillate is redistilled several times in  $\text{CO}_2$ .

**Properties.**—A dark-red, mobile, liquid; fumes much in the air; dissolves  $\text{Cl}$  and  $\text{I}$  in large quantities. The vapour absorbs all the light from a luminous flame except a narrow band in the red (Stoney a. Reynolds, P. M. [4] 41, 291). If the vapour is mixed with  $\text{O}$  and passed into a Bunsen lamp a violet flame is produced, showing lines in the violet, green, yellow, orange, and red, part of the spectrum (Gottschalk a. Drechsel, J. pr. 89, 473).  $\text{CrO}_2\text{Cl}_2$  is best kept in sealed glass tubes.

**Reactions.**—1. Easily parts with  $\text{O}$  and  $\text{Cl}$ ; acts as an energetic oxidiser and chlorinating agent, e.g. oxidises  $\text{P}$ ,  $\text{S}$ ,  $\text{Hg}$ , alcohol, turpentine, &c., oxidises and chlorinates  $\text{C}_2\text{H}_4$  (forming  $\text{C}_2\text{H}_2\text{Cl}_2\text{O}_2$ ),  $\text{C}_2\text{H}_6$  (forming  $\text{C}_2\text{H}_4\text{Cl}_2\text{O}_2$ ) &c. (v. Liebig, P. 21, 359; Schrötter, A. 37, 148; Heintze, J. pr. [2] 4, 211; Carstanjen, J. pr. [2] 2, 51).—2. Heated with  $\text{PCl}_5$ ,  $\text{POCl}_3$ , or  $\text{PCl}_3$ ,  $\text{CrCl}_3$  and  $\text{Cr}_2\text{O}_3$  are formed with evolution of  $\text{Cl}$  (Casselmann, A. 98, 213; Schiff, A. 102, 111; Weber, P. 107, 375; Cronander, B. 6, 1466).—3. With water,  $\text{CrO}_3\text{Aq}$  and  $\text{HClAq}$  are formed with production of much heat.—4. Decomposed, giving crystalline  $\text{CrO}_3$ , when passed through a warm tube (Wöhler, P. 33, 331).—5. Heated in a closed tube to  $180^\circ$ ,  $\text{CrO}_3\text{Cl}$  and  $\text{Cl}$  are formed (Thorpe, C. J. [3] 8, 31).—6. Iodine dissolves in  $\text{CrO}_2\text{Cl}_2$ ; on heating  $\text{CrO}_3\text{Cl}_2$  and  $\text{ICl}$  are formed (Macivor, C. N. 28, 138).—7. Reacts with  $\text{KClAq}$  to form  $\text{K}_2\text{CrO}_4\text{OKCl}$  (g. v. under **CHROMATES**) and  $\text{HClAq}$  (Péligot, A. Ch. 52, 287).—8. With  $\text{K}_2\text{CrO}_3\text{Aq}$  combines to form  $\text{CrO}_3\text{OKCl}$  (Geuther, A. 106, 240).—9. Burns in dry  $\text{NH}_3$  to form  $\text{NH}_4\text{Cl}$  and  $\text{CrO}_3$  (Rideal, C. J. 49, 387).

II. **TRICHROMYL CHLORIDE**  $\text{Cr}_2\text{O}_3\text{Cl}_2$  (*Chromium chromato-chloride*). Mol. w. unknown.

**Formation.**—1. Potassium chlorochromate,

$\text{CrO}_4\text{OK.Cl}$  is heated with conc.  $\text{H}_2\text{SO}_4$ ;  $\text{CrO}_4\text{Cl}_2$  and  $\text{Cr}_2\text{O}_7\text{Cl}_2$  are produced together (Zettnow, *P.* 143, 828).—2. I is dissolved in  $\text{CrO}_4\text{Cl}_2$ , and the product is distilled (Macivior, *C. N.* 28, 138).

**Preparation.**— $\text{CrO}_4\text{Cl}_2$  is heated in a closed tube for several hours to  $180^\circ$ , and the residue is heated in dry  $\text{CO}_2$  to  $120^\circ$  to remove unchanged  $\text{CrO}_4\text{Cl}_2$  (Thorpe, *C. J.* [2] 8, 31).

**Properties and Reactions.**—A black, amorphous, very deliquescent powder; heated in air,  $\text{O}$ ,  $\text{Cl}$ , and  $\text{Cr}_2\text{O}_3$  are formed; easily reduced by  $\text{H}$  to  $\text{Cr}_2\text{O}_3$  with evolution of  $\text{O}$  and  $\text{Cl}$ ; dissolves in  $\text{HClAq}$ ,  $\text{Cl}$  is evolved, and  $\text{CrCl}_3\text{Aq}$  remains; aqueous solution also gives off  $\text{Cl}$  on heating.

III. OXYCHLORIDES from  $\text{CrCl}_3\text{Aq}$  (Moberg, *J. pr.* 23, 175; Löwew, *J. pr.* 37, 38; Pélégot, *J. pr.* 37, 475; Schiff, *A.* 124, 157; Ordway, *Ann. S.* [2] 26, 197; Béchamp, *A. Ch.* [3] 56, 306; 57, 296). By evaporating  $\text{CrCl}_3\text{Aq}$  at  $120^\circ$  a reddish residue, soluble in  $\text{H}_2\text{O}$ , agreeing with composition  $\text{Cr}_2\text{O}_3.8\text{CrCl}_3.24\text{H}_2\text{O}$ , was obtained; this heated to  $150^\circ$  left a reddish-grey powder,  $\text{Cr}_2\text{O}_3.4\text{CrCl}_3.9\text{H}_2\text{O}$  ( $= \text{Cr}_2\text{OCl}_2.3\text{H}_2\text{O}$ ); when more strongly heated, and water added, a residue remained,  $2\text{Cr}_2\text{O}_3.2\text{CrCl}_3$  ( $= \text{CrOCl}$ ) (Moberg).  $\text{Cr}_2\text{OCl}_2$  was also obtained by heating  $\text{CrCl}_3.x\text{H}_2\text{O}$  to  $150^\circ$ – $260^\circ$ , and by long-continued digestion of  $\text{Cr}_2\text{O}_3.x\text{H}_2\text{O}$  with cold dilute  $\text{HClAq}$  (Löwew; Pélégot).

$\text{CrOCl}_3\text{H}_2\text{O}$  was obtained by adding  $\text{BaO.H}_2\text{Aq}$  to  $\text{CrCl}_3\text{Aq}$  until the pp. no longer dissolved, evaporating, treating the residue with alcohol ( $\text{BaCl}$  remained), evaporating to dryness at  $100^\circ$  and drying at  $120^\circ$  (Pélégot); the same compound was obtained by boiling  $\text{CrCl}_3\text{Aq}$  with  $\text{Cr}_2\text{O}_3.x\text{H}_2\text{O}$  (Béchamp).

Chromium, oxyfluoride of,  $\text{CrO}_2\text{F}_2$ . Said to be obtained by reaction between  $\text{PbCrO}_3$ ,  $\text{CaF}_2$ , and  $\text{H}_2\text{SO}_4$  (v. Oliveri, *G.* 16, 218).

Chromium, phosphide of,  $\text{CrP}$ . Mol. w. unknown. *S. G.* 4.68.

**Formation.**—1. By strongly heating  $\text{CrPO}_4$  with  $\text{C}$  (H. Rose, *P.* 34, 333)—2. By passing  $\text{PH}_3$  over hot  $\text{CrCl}_3$  (H. Rose, *l.c.*).

**Preparation.**—Pieces of  $\text{P}$  are placed in the closed end of a tube of very infusible glass; dry  $\text{K}_2\text{CrO}_4$  is placed at a little distance from the  $\text{P}$ . The  $\text{K}_2\text{CrO}_4$  is heated to redness; the  $\text{P}$  is then heated so that the vapour passes over the  $\text{K}_2\text{CrO}_4$ ; much heat and light are produced during the reaction. The product is treated with  $\text{H}_2\text{O}$ , which dissolves out  $\text{K}$  phosphates and leaves the  $\text{CrP}$  (Martius, *A.* 109, 82).

**Properties and Reactions.**—A grey-black, crystalline, metal-like powder; insoluble in all acids; heated in  $\text{O}$ , burns to  $\text{CrPQ}_4$ ; heated in  $\text{Cl}$ , forms  $\text{PCl}_3$  and  $\text{CrCl}_3$ ; oxidised by molten  $\text{KOH}$  with evolution of  $\text{H}$ , and by molten  $\text{KClO}_4$  with evolution of  $\text{Cl}$ .

Chromium, salts of. Compounds obtained by replacing  $\text{H}$  of acids by  $\text{Cr}$ . Two series of  $\text{Cr}$  salts exist; chromous salts  $\text{CrX}_2$ , and chromic salts  $\text{CrX}_3$ , where  $\text{X} = \text{Cl}$  &c.,  $\text{SO}_4$  &c.,  $\text{PO}_4$  &c.

The V. D. of two compounds of  $\text{Cr}$ , viz.  $\text{CrO}_2\text{Cl}_2$  and  $\text{CrCl}_3$ , have been determined; from this, and the S.H. of  $\text{Cr}$ , the value for the atomic weight of the element is found to be 52.4: the simplest formulae that can be given to the salts

of  $\text{Cr}$  ( $\text{Cr} = 52.4$ ) are  $\text{CrX}_2$  and  $\text{CrX}_3$ , but these formulae do not necessarily represent the composition of gaseous molecules.

Chromous chloride,  $\text{CrCl}_2$ , is the starting-point for preparing most of the chromous salts; these salts are red or blue, and soluble in water; they very quickly absorb  $\text{O}$ , becoming chromic salts; they also absorb  $\text{NO}$ , and also  $\text{C}_2\text{H}_4$  (Berthelot, *A. Ch.* [4] 9, 385). The most stable chromous salts at present known are the sulphate  $\text{CrSO}_4.7\text{H}_2\text{O}$ , blue crystals isomorphous with  $\text{FeSO}_4.7\text{H}_2\text{O}$ ; the acetate  $\text{Cr}(\text{C}_2\text{H}_3\text{O}_2)_2.x\text{H}_2\text{O}$ , red trimetric prisms; and the oxalate  $\text{CrC}_2\text{O}_4$ , yellow crystalline powder, more stable than any other chromous salt. (For more details of individual salts v. ACETATES, CARBONATES, BORATES, OXALATES, PHOSPHATES, SULPHATES, SULPHITES; also CHROMOUS BROMIDE, CHLORIDE, HYDROXIDE, SULPHIDE.)

The normal chromic salts,  $\text{CrX}_3$ , are obtained by dissolving  $\text{Cr}_2\text{O}_3.x\text{H}_2\text{O}$  in acids, or by double decomposition from soluble chromic salts obtained in this way; these salts may be regarded as derived from the hydroxide  $\text{Cr}_2\text{O}_3\text{H}_2$ . Numerous basic salts also exist, many derived from the hydroxide  $\text{Cr}_2\text{O}_3\text{H}_2$  (v. CHROMIC HYDROXIDES). The starting-point in the preparation of chromic salts is usually  $\text{K}_2\text{Cr}_2\text{O}_7$ ; a solution of this salt is heated with  $\text{HClAq}$ , or  $\text{H}_2\text{SO}_4\text{Aq}$ , and a reducing agent (commonly alcohol or  $\text{SO}_2\text{Aq}$ );  $\text{CrCl}_3\text{Aq}$  or  $\text{Cr}_2\text{S}_3\text{SO}_4\text{Aq}$  is thus obtained; addition of  $\text{NH}_4\text{Aq}$  pps.  $\text{Cr}_2\text{O}_3.x\text{H}_2\text{O}$ , from which the chromic salts are obtained by the action of acids. Very many chromic salts exist in two forms, one violet to red, the other green. In some cases both varieties are known in the solid form and with the same composition, e.g. red and green  $\text{Cr}_2\text{SO}_4$ ; in other cases only a violet salt is known in crystals, but a green solution is obtainable from this. Aqueous solutions of most of the violet salts when boiled become green; many of these solutions become red or violet again on cooling, sometimes only after standing a long time. Only the violet, or red, solutions yield crystalline salts; the green solutions give amorphous, gummy solids on evaporation. Various hypotheses have been suggested to account for these colour-changes. The change does not seem to be due to hydration and dehydration (Schrötter, *P.* 53, 513), as dehydrating agents do not effect the change from red to green (Doyer van Cleeff, *J. pr.* [2] 23, 58). The experiments of Krüger (*P.* 61, 218), Siewert (*A.* 126, 94), and Doyer van Cleeff (*J. pr.* [2] 23, 58) seem to show that in some cases at any rate, e.g. chrome-alum, the normal violet salt is partially decomposed, on boiling, into basic salt and acid, and that on cooling the normal (violet) salt is re-formed. Van Cleeff dialysed a green solution of chrome-alum, and found the dialysate to contain free  $\text{H}_2\text{SO}_4$ , and the liquid in the dialyser excess of  $\text{Cr}_2\text{O}_3$ ; he also dialysed a violet solution of chrome-alum, and found the same composition in the liquid, both inside and outside the dialyser. The same chemist also found that the violet solution became green on addition of a little  $\text{KOH}$ ,  $\text{NaOH}$ ,  $\text{NH}_3$ , or alkaline carbonates; and that a little acid sufficed to reproduce the violet colour. For details of individual salts v. the arts. CARBONATES, BORATES, NITRATES, SULPHATES, &c. &c.

Chromium, selenides of,  $\text{CrSe}$  and  $\text{Cr}_2\text{Se}_3$ . Moissan (*C. R.* 90, 817) describes these compounds as black powders;  $\text{Cr}_2\text{Se}_3$  obtained by heating  $\text{Cr}_2\text{O}_3$  in  $\text{Se}$  vapour, or  $\text{CrCl}_3$  in  $\text{H}_2\text{Se}$ ;  $\text{CrSe}$  obtained by heating  $\text{Cr}_2\text{Se}_3$  in  $\text{H}_2$  or  $\text{CrCl}_3$  in  $\text{H}_2\text{Se}$ .

Chromium, sulphides of,  $\text{Cr}$  and  $\text{S}$  combine when heated together to form  $\text{Cr}_2\text{S}_3$ ; the same sulphide is produced by heating  $\text{Cr}_2\text{O}_3$ ,  $\text{CrCl}_3$ ,  $\text{CrO}_3$ , &c., in  $\text{H}_2\text{S}$ . No sulphide of  $\text{Cr}$ , but only  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ , is produced by the action of  $\text{H}_2\text{S}$ , alkali sulphides, &c., on solutions of  $\text{Cr}$  salts.  $\text{Cr}_2\text{S}_3$  is reduced by  $\text{H}$  to  $\text{CrS}$ . The sulphide  $\text{Cr}_2\text{S}_3$  has also been obtained. Phipson (*C. N.* 4, 125) stated that a heptasulphide  $\text{Cr}_7\text{S}_{17}$  exists; but this has been disproved (v. Bender, *B.* 20, 756). Compounds of  $\text{Cr}_2\text{S}_3$  with  $\text{ZnS}$ ,  $\text{MnS}$ ,  $\text{FeS}$ , &c., are obtained indirectly, e.g.  $\text{ZnS} \cdot \text{Cr}_2\text{S}_3$ ;  $\text{Cr}_2\text{S}_3$  therefore resembles  $\text{Cr}_2\text{O}_3$  inasmuch as it acts as a feebly salt-forming sulphide towards more positive sulphides.

I. CHROMIC SULPHIDE  $\text{Cr}_2\text{S}_3$ . Mol. w. unknown. S.G. 3.77 (Schafarik, *J.* 1863, 225). *Preparation.* Dry  $\text{H}_2\text{S}$  is passed over  $\text{Cr}_2\text{O}_3$  heated to about  $440^\circ$ ; the product is powdered and again heated in  $\text{H}_2\text{S}$ , and finally washed with  $\text{H}_2\text{O}$ , and dried at  $100^\circ$  (Moissan, *C. R.* 90, 817).  $\text{Cr}_2\text{S}_3$  is also obtained by the action of  $\text{H}_2\text{S}$  on hot  $\text{CrCl}_3$  (Liebig, *P.* 21, 359); or on  $\text{Cr}_2\text{SO}_4$  (Traube, *A.* 66, 87); or by strongly heating  $\text{Cr}_2\text{O}_3$  in  $\text{CS}_2$  (H. Rose); or  $\text{K}_2\text{Cr}_2\text{O}_7$  in  $\text{CS}_2$  (Schafarik, *J.* pr. 90, 9; Müller, *P.* 127, 404); or by heating  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  with  $\text{S}$ , in absence of air (Berzelius).

*Properties and Reactions.*—Brown-black, lustrous powder, steel-grey if fused; not attacked by acids, except  $\text{HNO}_3$ ,  $\text{Aq}$  and *aqua regia*, which dissolve it. Heated in air, gives  $\text{SO}_2$  and  $\text{Cr}_2\text{O}_3$ ; in  $\text{Cl}_2$  gives  $\text{S}_2\text{Cl}_2$  and  $\text{CrCl}_3$ ; with molten  $\text{KNO}_3$ ,  $\text{K}_2\text{CrO}_4$ , and  $\text{K}_2\text{SO}_4$  are formed; heated in  $\text{H}_2$ , gives off  $\text{H}_2\text{S}$  and  $\text{S}$ , and  $\text{CrS}$  remains (Moissan, *C. R.* 90, 817).

*Combinations.*— $\text{Cr}_2\text{S}_3$  is not acted on by  $\text{KOH}$ ,  $\text{Aq}$  or  $\text{K}_2\text{SAq}$ ; but by heating  $\text{K}_2\text{CrO}_4$  with  $\text{K}_2\text{CO}_3$  and  $\text{S}$ , and washing with water, greenish-black crystals (S.G. 2.79) are obtained, which are easily soluble in  $\text{HNO}_3$ ,  $\text{Aq}$ ; these are probably a compound of  $\text{K}_2\text{S}$  and  $\text{Cr}_2\text{S}_3$  (Kopp, *C. R.* 19, 1156; Schafarik, *J.* pr. 90, 9). By heating  $\text{Cr}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ ,  $\text{MO} \cdot x\text{H}_2\text{O}$  (or  $\text{M}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ ), and  $\text{S}$ , in  $\text{S}$  vapour, and then in  $\text{CO}_2$  until no more  $\text{S}$  is given off, Gröger (*Sitz. W.* 81 [2nd part], 531) obtained compounds of the form  $\text{MS} \cdot \text{Cr}_2\text{S}_3$ ;  $\text{M} = \text{Zn}, \text{Fe}, \text{Mn}$ . (v. CHROMIUM, THIOACID OF).

II. CHROMOUS SULPHIDE  $\text{CrS}$ . Mol. w. unknown. A black powder, produced by heating  $\text{Cr}_2\text{S}_3$  in  $\text{H}_2$  or by heating  $\text{CrCl}_3$  in  $\text{H}_2\text{S}$  at  $440^\circ$  (Moissan, *C. R.* 90, 817). Unchanged by heating in absence of air; heated in air  $\text{Cr}_2\text{O}_3$  and  $\text{SO}_2$  are formed; heated in  $\text{Cl}_2$  gives  $\text{CrCl}_3$ ; scarcely acted on by acids.

III. CHROMIUM TETRASULPHIDE  $\text{Cr}_4\text{S}_{11}$ . Mol. w. unknown. A greyish-black powder; insoluble in  $\text{H}_2\text{O}$ ; slightly soluble in conc.  $\text{HCl}$ ,  $\text{Aq}$ , easily in conc.  $\text{HNO}_3$ ,  $\text{Aq}$ . Prepared by heating dry  $\text{Cr}_2\text{O}_3$  thoroughly mixed with excess of well-powdered  $\text{S}$  in  $\text{H}$  until no more  $\text{S}$  is given off, again mixing with  $\text{S}$  and again heating in  $\text{H}$  (Gröger, *Sitz. W.* 81 [2nd part], 531).

Chromium, sulphocyanides of, and derivatives of these compounds, v. SULPHOCYANIDES, under CYANIDES.

Chromium, thioacid of. No thioacid of  $\text{Cr}$  is known; but  $\text{Cr}_2\text{S}_3$  behaves towards some more positive metallic sulphides as a salt-forming sulphide; in this respect it may be regarded as the thioanhydride of *hypothetical thiochromous acid*,  $\text{H}_2\text{Cr}_2\text{S}_3$ . Gröger (*Sitz. W.* 81 [2nd part], 531) obtained the thiochromites  $\text{ZnCr}_2\text{S}_7$ ,  $\text{FeCr}_2\text{S}_7$ , and  $\text{MnCr}_2\text{S}_7$ , by heating mixtures of  $\text{Cr}$  hydroxide and hydroxide of  $\text{Zn}$ ,  $\text{Fe}$ , or  $\text{Mn}$ , with  $\text{S}$ , for some time, then powdering and heating in  $\text{S}$  vapour for several hours, and finally heating in  $\text{CO}$ , until  $\text{S}$  was no longer given off. These thiochromites are dark-brown or black powders, insoluble in  $\text{H}_2\text{O}$  and  $\text{HCl}$ ,  $\text{Aq}$ , soluble in  $\text{HNO}_3$ ,  $\text{Aq}$  and *aqua regia*. M. M. P. M.

CHROMIUM GROUP OF ELEMENTS.—*Chromium, Molybdenum, Tungsten, Uranium.*—These four metals were discovered towards the end of the eighteenth century. None of them is found in the free state in nature, and the minerals in which their salts occur are all comparatively rare. Chromium was obtained in 1797 by Vauquelin from a mineral now known to consist chiefly of lead chromate; in 1782 Hjelms prepared molybdenum from an acid earth-like compound, which Scheele had obtained four years earlier from molybdenum-glance, a substance until then supposed to be the same as galena; three years after the preparation of molybdenum a new metal was obtained by the brothers d'Elhuyar, by deoxidising an acid which they had prepared from the mineral wolframite. This acid was shown to be identical with that which Scheele had made in 1781 from the Swedish mineral tungstein, hence the new metal was called tungsten, or by some chemists wolfram. Uranium was the name given by Klaproth to a new metal obtained by him 1789 from pitchblende.

Chromium, molybdenum, and tungsten are obtained by reducing the oxides of these metals by carbon at a high temperature; uranium is prepared by removing chlorine from the chloride by means of sodium. These metals are very hard and very infusible; uranium is fairly malleable; the others are brittle. The table on p. 169 presents the prominent physical and chemical properties of the chromium metals.

#### General formulae and character of salts.

$\text{MO}$ ,  $\text{M}_2\text{O}_3$ ,  $\text{MO}_2$ ,  $\text{MO}_3$ ;  $\text{MS}$ ,  $\text{M}_2\text{S}_3$ ,  $\text{MS}_2$ ,  $\text{MS}_3$ ;  $\text{MCl}$ ,  $\text{MCl}_2$ ,  $\text{MCl}_3$ ,  $\text{MCl}_4$ ;  $\text{H}_2\text{MO}$ ,  $\text{H}_2\text{M}_2\text{O}_3$ , &c. The lowest oxides,  $\text{MO}$ , are scarcely known; hydrates of these oxides, when  $\text{M} = \text{Cr}$  or  $\text{Mo}$ , appear to exist; a few chromous salts, e.g.  $\text{CrSO}_4 \cdot 7\text{H}_2\text{O}$ , exist, but are unstable, and easily become chromic salts. Sesquioxides,  $\text{M}_2\text{O}_3$ , of  $\text{Cr}$  and  $\text{Mo}$  are known; the former dissolves in acids with production of well-marked salts, the chromic salts,  $\text{Cr}_2\text{SO}_4$ ,  $\text{Cr}_2\text{NO}_3$ ,  $\text{Cr}_2\text{PO}_4$ , &c.; the latter is easily oxidised to  $\text{MO}_3$ , when moist it dissolves in acids, but no definite salts have been obtained from such solutions. Dioxides,  $\text{MO}_2$ , of all the metals of the group have been prepared: of these,  $\text{CrO}_2$  is the least stable towards heat or the action of acids, it parts with oxygen at  $300^\circ$ , and dissolves in acids apparently without deoxidation, but without producing definite salts;  $\text{MoO}_2$  and  $\text{WO}_2$  also dissolve in acids and produce salts, which, however, have scarcely been obtained in definite crystalline form; the

solutions of  $\text{MoO}_3$  readily take up oxygen from the air; both oxides, when heated, are oxidised to  $\text{MO}_3$ ;  $\text{UO}_2$  dissolves in acids to form a series of uranous salts, e.g.  $\text{U}(\text{SO}_4)_2$ , which are fairly easily oxidised to uranyl salts, e.g.  $\text{UO}_2\text{SO}_4$ ; when this oxide is heated it becomes  $\text{U}_3\text{O}_8$ . The oxides  $\text{MO}_3$  are all anhydrides; the mono-hydrated oxides  $\text{MO}_3\text{H}_2\text{O} (= \text{H}_2\text{MO}_4)$  act as dibasic acids, forming salts  $\text{X}_2\text{MO}_4$ ; several series of salts derived from more complex hydrates of  $\text{MO}_3$  are also known, e.g.  $\text{X}_2\text{M}_2\text{O}_7$ ,  $\text{X}_2\text{M}_2\text{O}_8$ ,  $\text{X}_2\text{M}_2\text{O}_{11}$ , &c., in the case of each metal except Cr these di-, tri- or tetra-salts are more distinctly marked than the salts  $\text{X}_2\text{MO}_4$ . The anhydride  $\text{CrO}_3$  combines with some normal salts, e.g.  $\text{K}_2\text{CrO}_4$ ,  $\text{CrO}_3$ , and also with a few anhydrides, e.g.  $\text{CaO}$ ,  $\text{SO}_3$ ; when dissolved in warm acids it forms chromic salts ( $\text{Cr}_2\text{SO}_4$ , &c.) with

evolution of oxygen. The anhydrides  $\text{MoO}_3$  and  $\text{WO}_3$  form a series of complex compounds with anhydrides and water; e.g.

$\text{MoO}_3$  also combines with  $\text{SO}_3$  to form  $\text{MoO}_3\text{SO}_3$  ( $? \text{MoO}_2\text{SO}_4$ ). The anhydride  $\text{UO}_2$  dissolves in acids to form uranyl salts, e.g.  $\text{UO}_2\text{SO}_4$ ,  $\text{UO}_2(\text{NO}_3)_2$ , &c., which are more stable than the uranous salts derived from  $\text{UO}_2$ . The metals of the chromium group form several other oxides intermediate between those briefly described, e.g.  $\text{Cr}_2\text{O}_3$  intermediate between  $\text{Cr}_2\text{O}_3$  and  $\text{CrO}_2$ ,  $\text{W}_2\text{O}_5$  and  $\text{W}_6\text{O}_{11}$  between  $\text{WO}_2$  and  $\text{WO}_3$ ,  $\text{U}_3\text{O}_8$  and  $\text{UO}_2$  between  $\text{UO}_2$  and  $\text{UO}_3$ ; there are also indications of the existence of a more oxidised oxide than  $\text{CrO}_3$ ,

	CHROMIUM.	MOLYBDENUM.	TUNGSTEN.	URANIUM.
<b>Atomic Weights.</b>	52.4.	95.9.	183.6.	239.
One or more compounds of each element have been gasified; specific heats have been directly determined. Molecular weights unknown.				
<b>Melting points.</b>	Above m.p. of Pt (which is $2000^\circ - 2500^\circ$ ).	Infusible at full white heat.	Softens and agglomerates at white heat.	A full red-heat.
<b>Spec. grav. (approx.).</b>	6.5-6.8.	8.5-8.6.	18.2-19.2.	18.4-18.7.
<b>Specific heats.</b>	0.10 (? too low).	0.066.	0.0334.	0.028.
<b>Atom. weight.</b>	7.7.	11.3.	9.7.	12.9.
<b>Spec. grav. (approx.).</b>				
<b>Occurrence and preparation.</b>	Occurs chiefly as chrome-iron-stone, $\text{FeO} \cdot \text{Cr}_2\text{O}_3$ , in which $\text{FeO}$ is more or less replaced by $\text{MgO}$ &c., and $\text{Cr}_2\text{O}_3$ by $\text{Al}_2\text{O}_3$ &c.; also as lead chromate, &c.; not widely diffused; obtained by deoxidising $\text{Cr}_2\text{O}_3$ by C, or removing Cl from $\text{CrCl}_3$ by means of K or Zn, or by electrolysis of a solution of $\text{CrCl}_3$ containing $\text{CrCl}_3$ .	Occurs in small quantities as oxide and sulphide, also as lead or cobalt molybdate; obtained by reducing the oxide or chloride by H, or the oxide by C or by KCN.	Occurs very sparingly as tungstate of Ca, of Fe and Mn, and of Pb, also as oxide; obtained by reducing the oxide or chloride in hydrogen.	Sparingly distributed as oxide in pitchblende, as uranite of Ca and of Cu, as carbonate of U and Ca &c.; obtained by reducing the chloride by means of sodium.
<b>Physical properties.</b>	Very hard; brittle; crystalline powder composed of small, brilliant, tin-white crystals (? rhombohedra); descriptions of properties differ considerably, probably the metal has not been obtained in approximate purity.	Ashen-grey powder, or, when compressed, a silver-like, lustrous, hard, brittle, infusible metal.	Resembles iron in colour and lustre; very hard, and brittle; also obtained as a brown amorphous powder; forms a very hard durable alloy with iron.	White, lustrous; hard, softer than steel; somewhat malleable, but cannot be beaten into thin plates; also obtained as a grey-black powder.

TABLE—*cont.*

	CHROMIUM.	MOLYBDENUM.	TUNGSTEN.	URANIUM.
<i>Chemical properties.</i>	Burns in stream of O; somewhat more stable in air than iron; heated in air becomes covered with very thin film of oxide; oxidised by molten $\text{KNO}_3$ or $\text{KClO}_3$ , but not by molten $\text{Na}_2\text{CO}_3$ ; easily dissolved by dilute $\text{HCl}$ or $\text{H}_2\text{SO}_4$ , but not attacked by hot concentrated $\text{HNO}_3$ ; combines easily with Cl and I when heated; decomposes steam slightly at a red heat; forms a well-marked cyanide $\text{CrCy}_3$ . Replaces H of acids forming two series of salts; trioxide acts as an anhydride, forming chromic acid $\text{H}_2\text{CrO}_4$ , from which many salts are obtained; $\text{Cr}_2\text{O}_3$ also forms salts (chromites) by heating with $\text{ZnO}$ , &c. Atom of Cr is trivalent in $\text{CrCl}_3$ .	Not oxidised in air at ordinary temperature, but burns at low red heat; unacted on by $\text{HCl}$ , $\text{HF}$ , or dilute $\text{H}_2\text{SO}_4$ ; dissolves in conc. $\text{H}_2\text{SO}_4$ ; oxidised to $\text{MoO}_3$ by $\text{HNO}_3$ ; oxidised by molten $\text{KOH}$ , but not attacked by hot $\text{KOH}$ ; combines with Cl to form $\text{MoCl}_3$ when heated; also with Br to form $\text{MoBr}_3$ and $\text{MoBr}_2$ , but not with I; forms a nitride (? $\text{Mo}_3\text{N}_4$ ) when $\text{MoCl}_3$ is strongly heated in $\text{NH}_3$ . Salts in which H of acid is replaced by Mo scarcely known; $\text{MoO}_3$ acts as anhydride of $\text{H}_2\text{MoO}_4$ , from which acid several series of salts are obtained; $\text{MoO}_3$ also combines with acid radicles, e.g. $\text{SO}_3$ , $\text{P}_2\text{O}_5$ , &c. Forms many oxyhaloid salts. Atom of Mo pentavalent.	Unchanged in ordinary air, but burns in air at red heat; combines with Cl only at a high temperature, to form $\text{WCl}_6$ ; dissolves in boiling conc. $\text{KOH}$ to form K tungstate with production of H; oxidised to $\text{WO}_3$ by hot $\text{HNO}_3$ , $\text{H}_2\text{SO}_4$ , or $\text{HCl}$ ; forms a nitridamide, $\text{W}_2\text{N}_2\text{W}_2\text{NH}_3$ , by heating $\text{WCl}_6$ in $\text{NH}_3$ . Does not appear to form salts by replacing H of acids; $\text{WO}_3$ is the anhydride of the acid $\text{H}_2\text{WO}_4$ , which yields several series of salts; $\text{WO}_3$ also combines with acid radicles, e.g. $\text{SO}_3$ , $\text{SiO}_2$ , &c. Forms many oxyhaloid salts. Atom of W penta- and hexa-valent.	Slowly tarnishes in air; oxidised at $150^\circ\text{--}200^\circ$ in air, with evolution of light and sparks; combines with Cl or Br when heated to form $\text{UCl}_4$ and $\text{UBr}_4$ ; very slightly attacked by iodine vapour; heated in S vapour forms $\text{US}_3$ ; dissolves in warm dilute $\text{H}_2\text{SO}_4$ , with evolution of $\text{H}_2$ , easily in $\text{HCl}$ , also in $\text{HNO}_3$ (when melted and cooled it is nearly insoluble in $\text{HNO}_3$ ); does not decompose water; a nitride (? $\text{U}_3\text{N}_4$ ) formed by heating $\text{UCl}_4$ mixed with $\text{NH}_4\text{Cl}$ in $\text{NH}_3$ . Forms two series of salts, uranous, e.g. $\text{U}(\text{SO}_4)_3$ , and uranyl, salts, e.g. $\text{UO}_2(\text{SO}_4)$ ; $\text{UO}_2$ is the anhydride of $\text{H}_2\text{UO}_4$ , from which several salts are derived, the most marked being $\text{M}_2\text{U}_2\text{O}_7$ . Atom of U tetra-valent.

(?  $\text{Cr}_2\text{O}_3$ ), and the oxide  $\text{UO}_2$  is said to have been obtained in the hydrated state.

The sulphides  $\text{MS}$ , ( $\text{M} = \text{Mo}, \text{W}$ ) are acidic; sulpho-salts of the form  $\text{H}_2\text{MS}$ , are known.

Of the haloid compounds of these metals the following have been obtained as gases:  $\text{CrCl}_4$ ,  $\text{MoCl}_4$ ,  $\text{WCl}_4$ ,  $\text{UCl}_4$ ,  $\text{UBr}_4$ ; the formulae of these compounds represent the relative masses of their molecules. It is said that  $\text{CrF}_4$  has also been prepared in the state of gas, but the evidence is very doubtful; the oxychloride  $\text{CrO}_2\text{Cl}_2$  is an easily gasifiable body. Of the haloid compounds,  $\text{CrCl}_3$  and  $\text{UCl}_4$  are obtained by heating a mixture of  $\text{Cr}_2\text{O}_3$  and C, or of  $\text{UO}_2$  and C, in a stream of Cl gas; the former compound is very stable, the latter is reduced by strongly heating to  $\text{UCl}_3$ , which is again reduced to  $\text{UCl}_2$  by heating in hydrogen. When Mo or W is heated in chlorine, in the one case  $\text{MoCl}_3$  and the other case  $\text{WCl}_6$  is produced, the other chlorides are obtained by heating these in H or in  $\text{CO}_2$ . All the metals of this group readily form oxyhaloid salts.

Chromic chloride is a particularly interesting compound; it exists in two varieties, one (green) soluble in water and scarcely crystallisable, the other (violet) obtainable in well-formed crystals, but with difficulty soluble in water; some other chromic salts seem also to exist in two varieties, e.g. the sulphate  $\text{Cr}_2\text{SO}_4$  (v. CHROMIUM, CHLORIDES *op.*, p. 162). At least seven series of double compounds exist containing chromium, ammonia, and acid radicle (CHROMIUM, AMMONIO-SALTS *op.*, p. 158).

Of the four elements under consideration only Cr and U form well-marked salts by replacing the hydrogen of acids; these salts are not, however, analogous in composition or properties. The chromic salts are for the most part isomorphous with the salts of aluminium and the persalts of iron; the composition of these three groups of salts is also similar, e.g.  $\text{M}_2\text{SO}_4$ , where  $\text{M} = \text{Cr}, \text{Al}$ , or  $\text{Fe}$ . The uranyl salts— $\text{UO}_2\text{SO}_4$ , &c.—to a certain extent stand by themselves, although we know of many so-called

basic salts of chromium, iron, copper, &c., which resemble the uranyl salts in containing oxygen as well as metal and acid radicle.

Of the trioxides,  $\text{MO}_3$ , it may certainly be said that the most acidic in character is  $\text{CrO}_3$ , and the least acidic is  $\text{UO}_3$ ; this is in accordance with the general rule that the higher oxides of the elements in the same group (as group is used in the nomenclature of the periodic law) become less acid in character as the group is ascended.

The four elements all show distinct analogies with S, Se, and Te, which occur in the same group but in odd series; e.g. existence of acids  $\text{MO}_2(\text{OH})_2$ , and of anhydrides  $\text{MO}_3$ , &c.; but these three elements are more distinctly non-metallic in their properties than Cr, Mo, W, or U. The elements of the chromium group, as well as the three elements S, Se, and Te, show analogies with that element which is the first odd series member of the group, viz., oxygen (v. CLASSIFICATION, p. 207; also OXYGEN GROUP OF ELEMENTS. For detailed accounts of the properties of the elements of this group and their chief compounds v. CHROMIUM, MOLYBDENUM, TUNGSTEN, URANIUM, and for the other salts of these metals, v. CARBONATES, NITRATES, SULPHATES, &c.

M. M. P. M.

**CHROMYL CHLORIDE**  $\text{CrO}_2\text{Cl}_2$ , v. CHROMIUM, OXYCHLORIDES OF, p. 166.

**CHRUSOCREATININE**  $\text{C}_8\text{H}_8\text{N}_2\text{O}$ . A feebly alkaline substance said to occur in muscular tissue (Gautier, *Bl.* [2] 48, 18). Its solutions are ppd. by  $\text{HgCl}_2$ , by  $\text{ZnCl}_2$ , by iodine dissolved in aqueous KI, and by sodium phosphomolybdate. It forms a deliquescent hydrochloride and a crystalline platinochloride.

**CHRYSAMMIDIC ACID** v. TETRA-NITRO-OXY-AMIDO-ANTHRAQUINONE.

**CHRYSANILIC ACID** v. TETRA-NITRO-DI-OXY-ANTHRAQUINONE.

**CHRYSANILINE**  $\text{C}_{18}\text{H}_{13}\text{N}_3$ , *i.e.*

[267°-270°]. A by-product in the manufacture of rosaniline. Discovered by E. C. Nicholson and investigated by Hofmann (*C.R.* 55, 817; *B.2.* 379), who prepared methyl ethyl and phenyl derivatives.

**Preparation.**—Commercial 'phosphine,' which is chrysaniline nitrate, is dissolved in hot water, cooled, and slowly added to dilute  $\text{NaOH}$ . The base separates as a bright yellow flocculent pp. It is dried at 100° and crystallised from benzene, which retains homologues in the mother liquid (O. Fischer & G. Körner, *A.* 226, 177; *B.* 17, 203).

**Synthesis.**—By oxidising *opp*-tri-amido-triphenyl-methane  $[2:1]\text{NH}_2\text{C}_6\text{H}_4\text{CH}(\text{C}_6\text{H}_4\text{NH}_2)(4:1)$ , which is obtained by reduction of the product of condensation of *o*-nitro-benzoic aldehyde with aniline.

**Properties.**—Golden plates (from benzene)  $\text{C}_{18}\text{H}_{13}\text{N}_3$ ,  $\text{C}_{18}\text{H}_{13}$ . The benzene of crystallisation is easily expelled. Golden needles of  $\text{C}_{18}\text{H}_{13}\text{N}_3\cdot 2\text{aq}$

(from alcohol). Much less soluble in alcohol than its homologues. When pure it does not clot together when heated with  $\text{NaOH}$ . In small quantities it may be distilled without decomposition. It dyes wool and silk yellow.

**Reactions.**—1. Heated with conc.  $\text{HCl}$  (8 vols.) at 170°,  $\text{NH}_3$  is exchanged for  $\text{OH}$  and, on cooling, large red prisms of the hydrochloride of chrysophenol separate. These dissolve in  $\text{NaOH}$  aq., but on exactly neutralising, chrysophenol  $\text{C}_{18}\text{H}_{13}\text{N}_3\text{O}$ , separates as an orange pp., sl. sol. water, ether, or benzene, but v. sol. alcohol. From dilute alcohol it crystallises with 2aq. It is a yellow dye and a strong base, forming acid and neutral salts. It is insol. aqueous  $\text{Na}_2\text{CO}_3$ , but sol. aqueous  $\text{NaOH}$  (O. Fischer & G. Körner, *A.* 226, 181).—2. By diazotisation and treatment with alcohol it is converted into phenyl-acridine. Chrysaniline (10 g.) dissolved in  $\text{H}_2\text{SO}_4$  (50 g.) and water (4 g.) is well cooled and treated with nitrous acid gas in excess. The product (containing the diazo-sulphate) is slowly poured into boiling alcohol (600 g.). The alcohol is distilled off and the residue mixed with water and distilled with steam at 200°-250°. Phenyl-acridine [181°] passes over. 8g. pure chrysaniline gave 1 g. phenyl-acridine, or 40 p.c. of the theoretical yield.—3. MeI gives  $\text{C}_{20}\text{H}_{15}\text{Me}_2\text{N}_3\text{I}$ , which separates from water in red needles.  $\text{NH}_3$  converts it into  $\text{C}_{20}\text{H}_{15}\text{Me}_2\text{N}_3$ , whence  $\text{Ag}_2\text{O}$  forms  $\text{C}_{20}\text{H}_{15}\text{Me}_2\text{N}_3$ , a brown amorphous powder. EtI acts in the same way.

**Formation in the rosaniline melt:** This can be explained by two hypotheses: (1) That in the condensation of *p*-toluidine (1 mol.) with 2 mols. of aniline, together with the ordinary para-condensation producing rosaniline, a condensation simultaneously takes place which is partly ortho and produces *o*-di-*p*-tri-amido-methane, which by further oxidation yields chrysaniline—

(2) That *o*-di-*p*-tri-amido-methane is produced by condensation of 1 mol. of *o*-toluidine with 2 mols. of aniline. This latter hypothesis is the most probable and is supported by the above-mentioned synthesis (Fischer & Körner, *B.* 17, 203).

**Salts.**— $\text{B}^2\text{HCl}$ .— $\text{B}^2\text{HCl}$  aq.— $\text{B}^1\text{HCl}$ .— $\text{B}^1\text{HNO}_2$ .— $\text{B}^2\text{HNO}_2$ .

• Picric acid compound

$\text{B}^1(\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH})_2$  aq. (at 100°). Red needles.

**Di-acetyl-derivative**  $\text{C}_{20}\text{H}_{15}\text{N}(\text{NHAc})_2$ .—Microscopic needles, dissolves in alcohol with a blue fluorescence, nearly insol. water. It is nearly as strong a base as chrysaniline itself and forms salts which greatly resemble the corresponding salts of chrysaniline.— $\text{B}^1\text{HCl}$ : soluble yellow microscopic needles, dyes wool and silk yellow.— $\text{B}^1\text{HNO}_2$ : sparingly soluble crystalline pp. (Anschütz, *B.* 17, 433).

**CHRYSANISIC ACID** v. DI-NITRO-AMIDO-BENZOIC ACID.

$C_6H_4(OH) \begin{array}{c} \text{CH} \\ \text{CH} \text{ (OH)} \end{array} > C_6H_4(CH_3)(OH)$   
 Occurs in Goa powder (also called arrarobo powder) to the extent of about 70 p.c., from which it is extracted with  $C_6H_6$ . Small yellow leaflets, m. sol. benzene,  $CHCl_3$ , and acetic acid, sl. sol. alcohol or ether, insol. water. Insol.  $NH_4Aq$  (difference from chrysophanic acid). By leading air into the solution in KOH, chrysophanic acid is formed:  $C_{30}H_{20}O + 2O_2 = 2C_{15}H_8O_4 + 3H_2O$ . By distillation with zinc dust it yields methylanthracene.

**Di-acetyl derivative.** Light yellow leaflets.

**Tetra-acetyl derivative** [228°–230°]. Yellowish prisms; sl. sol. alcohol with a blue fluorescence. By oxidation with  $CrO_3$  it gives di-acetyl-chrysophanic acid (Liebermann a. Sessler, *B.* 11, 1603; A. 212, 29; cf. De Silva, *Ph.* [3] 5, 723; Holmes, *Ph.* [3] 5, 801).

**CHRYSATIC ACID**  $C_{21}H_{18}N_2O_8$  (Mulder, *J. pr.* 48, 16; A. 72, 289) or  $C_{21}H_{18}N_2O_8$  (Schunck, A. 65, 240). An acid obtained by heating chrysamic acid with aqueous KOH. Sol. water.

**CHRYSATROPIC ACID**  $C_{21}H_{18}O_8$ . [202°]. S. (hot water) 1-3. An acid extracted by ether from an acidified infusion of the root or leaves of *Atropa belladonna* (Kunz, *Ar. Ph.* [3] 23, 722). Pale yellow trimetric prisms; may be sublimed. Sl. sol. cold water. Its alcoholic solutions exhibit green fluorescence.

**CHRYSAZIN** v. DI-OXY-ANTHRAQUINONE.

**CHRYSAZOL** v. DI-OXY-ANTHRACENE.

**CHRYSENE**  $C_{18}H_{12}$  i.e.  $\begin{array}{c} C_{18}H_{12}CH \\ | \\ C_6H_5 \cdot CH \end{array}$  Mol. w.

228. [250°]. (above 360°). S. (alcohol) 0.37 at 16°; 17 at 78°; 8. (toluene) 24 at 18°; 5.39 at 100° (Bechi, *B.* 12, 1978). V.D. 7.95 (calc. 7.89).

**Occurrence.**—In coal-tar, in petroleum, and in the product of the dry distillation of fats, fir-wood, amber, and resins (Laurent, *A. Ch.* [2] 66, 186; Berthelot, *Bl.* [2] 7, 30; *J.* 1867, 605; Pelletier a. Walter, A. 48, 345; Williams, *J. pr.* 67, 248; Adler, *B.* 12, 1891; Prunier, *A. Ch.* [5] 17, 5).

**Formation.**—1. By passing naphthyl-phenyl-ethane through a red-hot tube (Graebe a. Bunger, *B.* 12, 1079).—2. The statement that chrysene is among the products of the passage of benzene through a red-hot tube has been contradicted (Berthelot, *J.* 1867, 605; *Bl.* [2] 7, 30; 22, 487; G. Schultz, *B.* 6, 415).—3. Among the products obtained by passing benzene-azo-benzene through a red-hot tube (Claus a. Suckert, *B.* 8, 87).

**Properties.**—Colourless scales or flat trimetric octahedra (from benzene); *abc* = 1:1.376:2.490; v. sl. sol. alcohol, sl. sol. ether and cold  $CS_2$ , m. sol. boiling benzene and HOAc. The solutions as well as the crystals exhibit deep reddish-violet fluorescence. Hot conc.  $H_2SO_4$  forms a blue solution (Liebermann, A. 158, 299).  $CrO_3$  in HOAc gives chrysoquinone (*q. v.*). By exhaustive chlorination with  $SbCl_5$  it yields  $CCl_4$ ,  $CCl_2$ , and per-chloro-benzene (Merz a. Weith, *B.* 16, 2881).

#### Picric acid compound

$C_{18}H_{12}C_6H_2(NO_2)_3OH$ . Reddish-brown needles (from crude xylene) (Galletly, *C. N.* 10, 243). Decomposed by alcohol.

**Di-nitro-anthroquinone compound**  $C_{18}H_{12}C_{10}H_6(NO_2)_2O_2$ . [204°]. Formed by dissolving greenish-yellow commercial anthracene [208°] (50g.) in alcohol (5 litres) and adding  $HNO_3$  (30g. of S.G. 1.4), and boiling. Red needles; v. sl. sol. alcohol, ether, and benzene. Tin and HCl reduce the di-nitro-anthraquinone, setting free pure chrysene, which may conveniently be prepared in this way.

**Di-chloro-chrysene**  $C_{18}H_{12}Cl_2$ . [267°]. From chrysene and  $Cl_2$ . Soft white needles (from benzene); v. sl. sol. alcohol; may be sublimed.

**Tri-chloro-chrysene**  $C_{18}H_9Cl_3$ . [above 300°]. Slender needles (from benzene). From chrysene and  $Cl_2$  at 170° (Schmidt, *J. pr.* [2] 9, 270).

**Di-bromo-chrysene**  $C_{18}H_{10}Br_2$ . [273°]. From Br and chrysene in  $CS_2$ . White needles (from benzene); v. sl. sol. all menstrua. Not attacked by alcoholic KOH below 180°.  $K_2Cr_2O_7$  and  $H_2SO_4$  oxidise it to chrysoquinone.

**Nitro-chrysene**  $C_{18}H_{11}NO_2$ . From chrysene and  $HNO_3$  (S.G. 1.25) at 100°. [209°]. Thick prisms, grouped in stars (from benzene). May be sublimed; v. sl. sol. alcohol, ether, and  $CS_2$ .

**Di-nitro-chrysene**  $C_{18}H_{10}(NO_2)_2$ . [above 300°]. From chrysene and boiling  $HNO_3$  (S.G. 1.3). Slender yellow needles (from HOAc). V. sl. sol. alcohol, ether, and benzene.

**Tetra-nitro-chrysene**  $C_{18}H_8(NO_2)_4$ . [above 300°]. From the preceding and fuming  $HNO_3$ . Yellow needles (from HOAc). Detonates above 300°.

**Tri-bromo-di-nitro-chrysene**  $C_{18}H_7(NO_2)_2Br_3$ . Yellowish-red needles. Sol. hot alcohol, less in  $C_6H_6$  and ether. Prepared by the action of bromine on tetra-nitro-chrysene (Adler, *B.* 12, 1894).

**Isomeride of chrysene**  $C_{18}H_{12}$ . [196]. A by-product in the preparation of diphenyl by action of sodium on bromo-benzene (Schultz, A. 174, 229). Long needles (from alcohol). Is perhaps triphenylene (Schmidt a. Schultz, A. 203, 135).

**Isomeride of chrysene (?)**  $C_{18}H_{12}$ . [186°]. A product of the action of  $AlCl_3$  on a mixture of naphthalene and phthalic anhydride (Ador a. Crafts, *C. R.* 88, 1355). Laminæ (from ether-alcohol). Its bromo-derivative melts at 112°.

**CHRYSEUDIENE**. A hydrocarbon, obtained in small quantity in the distillation of aluminum ( $\beta$ )-naphthol (Gladstone a. Tribe, *C. J.* 41, 16).

**CHRY SIN**  $C_{18}H_{10}O$ . *Chrysinic acid*. [275°]. S. (cold alcohol) 0.6; (hot alcohol) 2. Occurs in the buds of *Populus nigra*, *P. pyramidalis*, and *P. balsamifera* (Piccard, *B.* 6, 884; 7, 888; 10, 176). The alcoholic extract, after successive treatment with lead acetate and  $H_2S$ , is evaporated, and the residue recrystallised from spirit and washed with alcohol, ether,  $CS_2$ , boiling water, and boiling benzene. The residue is heated to 275°, and crystallised from spirit. Bright yellow plates. Insol. water, nearly insol. benzene,  $CS_2$ , and chloroform. Aqueous alkalis form a yellow solution, but on boiling they split it up into phloroglucin, acetophenone, benzoic acid, and acetic acid. Lead acetate gives, in alcoholic solutions, a pp. soluble in excess.

$\text{Fe}_2\text{Cl}_6$  gives a violet colour in alcoholic solution.

**Di-bromo-chrysin**  $\text{C}_{15}\text{H}_8\text{Br}_2\text{O}_4$ . Formed by adding  $\text{Br}^+$  to an alcoholic solution of chrysin. Felted mass of silky needles.

**Di-chloro-chrysin**. Needles.

**Di-iodo-chrysin**  $\text{C}_{15}\text{H}_8\text{I}_2\text{O}_4$ . Formed by adding iodine and iodic acid to an alcoholic solution of chrysin.

**Di-nitro-chrysin**  $\text{C}_{15}\text{H}_8(\text{NO}_2)_2\text{O}_4$ . From chrysin and  $\text{HNO}_3$ . Large crystals (from hot  $\text{HOAc}$  or aniline). Forms an orange-red basic ammonium salt and a yellow acid ammonium salt.

**Methyl derivative**  $\text{C}_{15}\text{H}_{11}\text{MeO}_4$ . *Tecto-chrysin*. [164°]. From chrysin,  $\text{MeI}$ , and  $\text{KOH}$  dissolved in  $\text{MeOH}$ . Exists in poplar-buds together with chrysin, from which it may be separated by means of its much greater solubility in benzene and chloroform. It is much less soluble in alcohol than chrysin. Large sulphur-yellow monoclinic prisms (from alcohol);  $a:b:c = 1.54:1.1:86$ ;  $\beta = 53^\circ$ . Insol. alkalis. It forms a di-bromo-derivative.

**Ethyl derivative**  $\text{C}_{15}\text{H}_{13}\text{EtO}_4$ . [146°].

**Iso-amyl derivative**  $\text{C}_{15}\text{H}_{19}(\text{C}_4\text{H}_9)\text{O}_4$ . [125°]. Its di-bromo-derivative crystallises in needles.

**CHRYSOFLUORENE**  $\text{C}_{11}\text{H}_{12}$  i.e.  $\begin{array}{c} \text{C}_6\text{H}_5 \\ \diagup \quad \diagdown \\ \text{C}_5\text{H}_7 \end{array} \text{CH}_2$

[188°]. Silvery glistening tables. V. e. sol. ether, chloroform, and benzene, less sol. cold alcohol. Formed by heating chrysoketone with  $\text{HI}$  and  $\text{P}$  at  $150^\circ$ – $160^\circ$  (Bamberger a. Kranzfeld, *B.* 18, 1934).

**Chrysofluorene alcohol**  $\begin{array}{c} \text{C}_6\text{H}_5 \\ \diagup \quad \diagdown \\ \text{C}_5\text{H}_7 \end{array} \text{CH(OH)}$

[167°]. Formed by reduction of chrysoketone with zinc and  $\text{HCl}$  (B. a. K.). White silky needles or glistening plates. Sublimable. V. sol. alcohol, ether, and benzene, sl. sol. ligroin. Its alcoholic solution is turned blue by addition of  $\text{H}_2\text{SO}_4$ . Strong  $\text{H}_2\text{SO}_4$  dissolves it with a reddish-violet colour.

**CHRYSOGEN** *C.* 94.3 to 95 p.c.; *H* 5.7 to 5 p.c. [280°–290°]. *S.* (cold benzene) .04; (boiling benzene) .2; *S.* (boiling  $\text{HOAc}$ ) .05; (cold  $\text{HOAc}$ ) .01. An orange-coloured hydrocarbon contained in small quantity in crude anthracene, and separated therefrom by repeated crystallisation from benzene (Fritzsche, *C. R.* 51, 910; *Bl.* [2] 6, 474; Prunier, *Bl.* [2] 31, 293). Orange tables with green lustre; may be sublimed. Conc.  $\text{H}_2\text{SO}_4$  dissolves it without change. Small quantities colour white hydrocarbons yellow. Its solution is bleached by sunlight. It forms, with di-nitro-anthraquinone, a compound crystallising in olive needles with golden lustre.

**CHRYSOGLYCOLLIC ACID**

$\begin{array}{c} \text{C}_6\text{H}_5 \\ \diagup \quad \diagdown \\ \text{C}_{10}\text{H}_7 \end{array} \text{C(OH)}_2\text{CO}_2\text{H}$ . White powder. Formed by boiling freshly precipitated amorphous chrysoquinone with alkalis (Bamberger a. Kranzfeld, *B.* 18, 1938).

**CHRYSOIDINE** v. *Benzene-azo-m-phenylene diamine*.

**CHRYSOKETONE**  $\begin{array}{c} \text{C}_6\text{H}_5 \\ \diagup \quad \diagdown \\ \text{C}_{10}\text{H}_7 \end{array} \text{CO}$ . [130°]. Glis-

tening red needles. Scarcely volatile with steam. V. sol. the ordinary solvents. Formed by the oxidation of chryso-glycollic acid

$\begin{array}{c} \text{C}_6\text{H}_5 \\ \diagup \quad \diagdown \\ \text{C}_{10}\text{H}_7 \end{array} \text{C(OH)}_2\text{CO}_2\text{H}$  with  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$

(Bamberger a. Kranzfeld, *B.* 18, 1933).

**CHRYSO-NAPHTHAZINE**  $\text{C}_{23}\text{H}_{16}\text{N}_2$  i.e.

$\begin{array}{c} \text{C}_{10}\text{H}_6 \\ \diagup \quad \diagdown \\ \text{N} \end{array} \text{C}_{10}\text{H}_6$ . Formed by mixing a solu-

tion of chrysoquinone in aqueous-alcoholic  $\text{NaHSO}_3$  with an aqueous solution of naphthyl-ene-*o*-diamine hydrochloride, sodium acetate, and acetic acid. Yellow microcrystalline powder (Liebermann a. Witt, *B.* 20, 2443).

**CHRYSOPHANIC ACID** v. *Di-oxy-METHYL-ANTHRAQUINONE*.

**CHRYSOPHANIN**. A white amorphous substance said to be contained in the aqueous decoction of senna leaves (Bourgoin, *C. R.* 73, 1449).

**CHRYSOPHENOL**  $\text{C}_{15}\text{H}_{13}\text{N}_2\text{O}$ . *Oxy-amido-phenyl-acridine*. Formed by heating chrysani-line with  $\text{HCl}$  under pressure at  $180^\circ$ ,  $\text{NH}_2$  being replaced by  $\text{OH}$  (Fischer a. Körner, *B.* 17, 205). Small yellowish-red needles (containing aq.). Sl. sol. water, benzene, and ether, v. sol. alcohol and caustic alkalis. The hydrochloride and sulphate form sparingly soluble yellow crystals.

**CHRYSOQUINONE**  $\text{C}_{18}\text{H}_{10}\text{O}_2$  i.e.  $\begin{array}{c} \text{C}_{10}\text{H}_6 \\ \diagup \quad \diagdown \\ \text{C}_8\text{H}_4 \end{array} \text{CO}$

or  $\begin{array}{c} \text{C}_{10}\text{H}_6 \\ \diagup \quad \diagdown \\ \text{C}_8\text{H}_4 \end{array} \text{CO}$ . Mol. w. 258. [235°]. Occurs

in American petroleum to which, according to Punnier (*Bl.* [2] 31, 293), it imparts the blue fluorescence. Obtained by oxidising chrysene with  $\text{CrO}_3$  in  $\text{HOAc}$  (Liebermann, *A.* 158, 809; Graebe, *B.* 7, 782; E. Schmidt, *J. pr.* [2] 9, 250, 270). Orange plates (from alcohol); m. sol. benzene and  $\text{HOAc}$ , sl. sol. ether and  $\text{CS}_2$ . May be sublimed. Conc.  $\text{H}_2\text{SO}_4$  forms a deep-blue solution whence it is pptd. unaltered by water.  $\text{NaHSO}_3$  forms a crystalline compound, decomposed by much water.

**Reactions.**—1.  $\text{KMnO}_4$  gives phthalic acid (Anschütz a. Japp, *B.* 11, 211).—2. Distillation over *zinc-dust* forms chrysene.—3. Aqueous  $\text{SO}_2$  at  $100^\circ$  forms hydro-chrysoquinone. This body is also formed by the action of *zinc-dust* and aqueous  $\text{KOH}$ . It is an amorphous white powder, re-oxidised by air at  $200^\circ$ , or by shaking its solution in  $\text{H}_2\text{SO}_4$  with air.—4.  $\text{PCl}_5$  and  $\text{POCl}_3$  at  $200^\circ$  form di-chloro-chrysoquinone and deca-chloro-chrysene.—5. Distillation with *soda-lime* gives a hydrocarbon  $\text{C}_{18}\text{H}_{12}$  (? phenyl-naphthalene).—6. Heated with *benzoic aldehyde* and aqueous  $\text{NH}_3$  in sealed tubes at  $100^\circ$  it forms a product which, if boiled first with alcohol and then with benzene, yields to the latter a body  $\text{C}_{25}\text{H}_{18}\text{NO}$  crystallising in silky needles [259°–265°] which may be sublimed. The reaction is analogous to that of benzoic aldehyde and ammonia on phenanthraquinone (*q. v.*), hence this body should be  $\begin{array}{c} \text{C}_{10}\text{H}_6 \\ \diagup \quad \diagdown \\ \text{C}=\text{O} \\ \parallel \\ \text{C}=\text{N} \end{array} \text{C}.\text{Ph}$  (Japp a. Streatfield, *C. J.* 41, 157).

**Di-chloro-chrysoquinone**  $C_{18}H_8Cl_2O_2$ . From chrysene  $POCl_3$  and  $PCl_5$  (2 mols.) at  $200^\circ$ ; a yellow flocculent pp. is then obtained by adding alcohol (L.).

**Di-bromo-chrysoquinone**  $C_{18}H_8Br_2O_2$ . Red leaflets. [ $160^\circ$ – $165^\circ$ ]. Prepared by bromination of chrysoquinone (Adler, B. 12, 1893).

**Di-nitro-chrysoquinone**  $C_{18}H_8(NO_2)_2O_2$ . [230°]. From chrysoquinone and  $HNO_3$  (S.G. 1.4) (A.). Red needles.

**Tetra-nitro-chrysoquinone**  $C_{18}H_8(NO_2)_4O_2$ . From chrysoquinone and cold conc.  $HNO_3$ . Orange powder (L.).

**Chrysoquinone-di-sulphonic acid**

$C_{18}H_8(SO_3H)_2O_2$ .—Ba" (A.).

**Di-oxy-chrysoquinone**  $C_{18}H_8(OH)_2O_2$ . *Chrysoezarin*. [above  $800^\circ$ ]. Said to have been extracted from crude artificial alizarin (Claus, B. 8, 157). Dark brown needles with bronze lustre (from HOAc). Insol. cold water, sol. alcohol, ether, and alkalis.

**CHRYSO-TOLU-AZINE**  $C_{22}H_{16}N_2$ , i.e.

Prepared by mixing a solution of chrysoquinone in aqueous-alcoholic  $NaHSO_4$  with an aqueous solution of tolylene-o-diamine hydrochloride, sodium acetate, and acetic acid. Small golden needles. Sublimable. Dissolves in conc.  $H_2SO_4$  with a blackish-violet colour (Liebermann & Witt, B. 20, 2443).

**CHRYSO-TOLUIDINE**  $C_{22}H_{16}N_2$  (?). Found among the by-products in the preparation of rosaniline (DeLaire, Girard, & Chapoteaut, C. R. 63, 964).

**CICUTA OIL**. The oil from the seeds of *Cicuta virosa* is of the same nature as Roman oil of chamomile (q. v.) (Trapp, J. pr. 74, 423).

**CICUTENE**  $C_{15}H_{16}$ . [160°]. A dextrorotatory terpene in the essential oil obtained from the root of the water-hemlock, *Cicuta virosa* (Ankum, Z. 1869, 248). The same plant is said to contain an alkaloid, Cicutine (Polex, Ar. Ph. 18, 174; Wittstein, Buchner's Repts. 18, 19).

**CIMICIC ACID**  $C_{15}H_{16}O_2$ . Mol. w. 240. [44°]. Occurrence.—In the fatid oil ejected by a kind of bug *Rhaphigaster punctipennis* when irritated. The insects are washed with alcohol, and the residue extracted with ether (Carius, A. 114, 147). Occurs also in spider's web (Valente, G. 12, 557).

**Properties**.—Prisms (from ether), lighter than water. Insol. water, v. sl. sol. alcohol, v. sol. ether. Has a rancid odour.

**Salts**.—NaA'.—KA': amorphous.

**Chloride**  $C_{15}H_{15}OCl$ : [c.  $44^\circ$ ].

**Ethyl ether EtA'**. Oil.

**CIMICIC ALDEHYDE**  $C_{15}H_{14}O$ . [72°]. Occurs in spider's web (Valente, G. 12, 557). Reduces Fehling's solution and ammoniacal  $AgNO_3$ .

**CINCHAMIDINE** v. CINCHONA BASES.

**CINCHENE**  $C_{19}H_{19}N$ . *Cinchotidine*. [125°]. Formed by treatment of cinchonine or cinchonidine with  $PCl_5$ , and boiling the resulting cinchonine-chloride  $C_{19}H_{17}Cl$  or cinchonidine chloride with alcoholic KOH. Trimetric tables  $a:b:c = 6017:1:5022$ . By heating with HCl at  $220^\circ$ – $230^\circ$  it is converted into apocinchene  $C_{18}H_{17}NO$ , MeCl and  $NH_3$ , being split off and  $H_2O$  taken up (Comstock & Königs, B. 14, 1854; 17, 1889).

**Methylo-iodide** B'MeI: [186°]; monosym-

metrical tables,  $a:b:c = 1:5838:1:9114$ ; v. sol. alcohol, sl. sol. water, scarcely sol. ether (Comstock & Königs, B. 18, 1219).

(a)-Cinchene-di-bromide  $C_{18}H_{15}Br_2N$ . [118°]. Formed, together with about an equal quantity of (β)-cinchene-di-bromide, by the addition of bromine to cinchene (Comstock & Königs, B. 19, 2858; 20, 2512). Monosymmetrical crystals,  $a:b:c = 9570:1:8686$ ,  $\beta = 65^\circ 52'$ . Converted by boiling with alcoholic KOH into dehydrocinchene. The hydrobromide forms concentric needles; the nitrate small, colourless crystals, sl. sol. dilute  $HNO_3$ ; the zinc-double chloride colourless needles [c.  $250^\circ$ ].

(β)-Cinchene-di-bromide  $C_{18}H_{15}Br_2N$ . [134°]. Formed, together with (a)-cinchene-di-bromide [113°], and in about equal quantity, by the addition of bromine to cinchene. Rhombic sphenoidal hemihedral crystals,  $a:b:c = 5552:1:12017$ . Somewhat less sol. alcohol and ether than the (a)-isomeride. Like the (a)-isomeride it is converted by boiling with alcoholic KOH into dehydrocinchene. The hydrobromide forms granular crystals more soluble than the (a)-hydrobromide (separation). The zinc-double chloride forms colourless needles [c.  $250^\circ$ ]. The nitrate separates in the form of a jelly, sl. sol. dilute  $HNO_3$  (C. & K.).

**Cinchene-bromo-hydride**  $C_{18}H_{15}BrN$ . *Hydrobromcinchene*. [105°–116°]. Formed by dissolving cinchene in cooled, HBr and allowing to stand for two days. Monoclinic crystals,  $a:b:c = 8541:1:8280$ ,  $\beta = 63^\circ 7'$ ; isomorphous with cinchene-di-bromide. V. sol. alcohol, ether, benzene, chloroform, and acetic ether, sl. sol. ligroin (Comstock & Königs, B. 20, 2522).

**Dehydrocinchene**  $C_{18}H_{17}N$ . [c.  $60^\circ$  hydr.]. Obtained by boiling dehydrocinchonine chloride,  $C_{18}H_{15}N_2Cl$  or (a)- or (β)-cinchene-di-bromide  $C_{18}H_{15}Br_2N$ , with alcoholic KOH. Long colourless needles (with 3aq).—B'H $_2$ Br $_2$ : very soluble small prisms.—B'H $_2$ Cl $_2$ PtCl $_4$ : very sparingly soluble red tables (Comstock & Königs, B. 19, 2857).

**Apocinchene**  $C_{18}H_{17}NO$ . [209°]. Formed by heating cinchene with HCl at  $220^\circ$ – $230^\circ$  (Comstock & Königs, B. 14, 1854; 17, 1886; 18, 2379; 20, 2674). Colourless needles. Sol. alcohol, acids, and alkalis. The compounds which it forms with acids and with bases are dissociated by water.

**Reactions**.—By fusion with KOH or NaOH it gives oxy-apocinchene  $C_{18}H_{17}NO_2$ . Its ethers are oxidised by  $CrO_3$  to cinchononic acid; on oxidation with dilute  $HNO_3$  they yield alkyl-apocinchonic acids  $C_{18}H_{17}(OR)N.CO_2H$ .

**Salts**.—B'HBr. [c.  $256^\circ$ ]: yellow needles (from alcoholic HBr).—B'HI.—B'HPtCl $_4$ . [c.  $235^\circ$ ].\* The Ag salt is a nearly insoluble pp.

**Acetyl derivative**  $C_{18}H_{17}AcNO$ . [119°].

**Methyl ether**  $C_{18}H_{19}(OMe)N$ : oil; v. sol. alcohol, ether, &c., nearly insol. water. B'HCl $\frac{1}{2}$ aq: [c.  $198^\circ$ ], crystalline solid.

**Ethyl ether**  $C_{18}H_{19}(OEt)N$ : [71°]; colourless prisms.

**Bromo-apocinchene**  $C_{18}H_{17}BrNO$ . [188°]. From apocinchene hydrobromide in chloroform and HOAc by adding Br. Crystalline, v. sol. aqueous alkalis, benzene, and chloroform, less sol. alcohol and ether.  $CrO_3$  oxidises it to bromoform and cinchononic acid. Boiling alcoholic NaOH does not attack it.

**Di-bromo-apocinchene.** *Ethyl ether*  $C_{15}H_{10}Br_2(OEt)N$ . [118°]. From ethyl-apocinchene (10 g.) and Br (15 c.c.)

**Oxy-apocinchene**  $C_{15}H_{10}NO_2$ . [117°]. Formed by fusing apocinchene  $C_{15}H_{10}(OH)N$  with KOH or NaOH (Comstock & Königs, *B.* 18, 2385). Colourless crystals. V. sol. caustic alkalis, sl. sol. cold alcohol and pure ether, nearly insol. water and dilute acids.

*Acetyl derivative*  $C_{15}H_{10}AcO_2$ . [203°].

**Methyl-apocinchenic acid**

$C_{15}H_{12}(OMe)N.CO_2H$ . [231°]. Formed by oxidation of the methyl ether of apocinchene with dilute  $HNO_3$  (Comstock & Königs, *B.* 18, 2383). Colourless crystals. V. sol. alcohol, acids and alkalis, nearly insol. water.

**Ethyl-apocinchenic acid**  $C_{15}H_{12}(OEt)N.CO_2H$ . Formed by oxidation of the ethyl ether of apocinchene  $C_{15}H_{10}(OEt)N$  with dilute  $HNO_3$  (Comstock & Königs, *B.* 18, 2384; 20, 2674). Crystallises from absolute alcohol in yellowish anhydrous needles [152°]; from dilute alcohol in crystals (containing aq) [126°]. By heating with HCl at 130° it is split up into  $CO_2$ , EtCl, and homo-apocinchene  $C_{15}H_{12}NO_2aq$  [185°]. The hydrobromide of homoapocinchene  $BHBr aq$  crystallises in yellow needles or prisms [222°] sl. sol. water. Homo-apocinchene on fusion with potash gives an acid [230°] split up by heat into  $CO_2$  and another acid  $C_{15}H_{12}NO_2$  (?) [223°].

**Salts.**—The Ag, Cu, Ba, Pb, Zn, and Cu salts are sparingly soluble. —  $AgA'$ . —  $(HA')_2H_2PtCl_6$ .

**CINCHOL**  $C_{20}H_{24}O$ . [130° water-free]. Is found in all true cinchona barks but not in *C. cuprea*; in largest amount (up to 0.03 p.c.), along with some quebrachol, in *C. Calisaya* Var. *Ledgeriana*. Found also along with cupreol. Helms' 'Cinchocerotine' (*Ar. Ph.* [3] 21, 279) was probably wholly or partly cinchol. Further, Liebermann's 'Oxy-chino-terpene' (*B.* 17, 871) is cinchol (Hesse).

**Preparation.**—From crude cupreol, the acetate being separated by repeated crystallisations from alcohol from the acetates of quebrachol and cupreol (O. Hesse, *A.* 228, 288; 234, 375).

**Properties.** Plates (containing aq) from alcohol. Lævoroatory in chloroform solution;  $[\alpha]_D = -34.8^\circ$  (in a 6 p.c. solution). Its properties are similar to those of cupreol.

*Acetyl derivative*  $C_{20}H_{22}O(C_2H_3O)$ . [124°]. White needles from alcohol. M. sol. alcohol, v. sol. ether and chloroform. Lævoroatory (in chloroform);  $[\alpha]_D = -41.7^\circ$  (in a 4 p.c. solution).

*Propionyl derivative*  $C_{20}H_{22}O(C_3H_5O)$ . [110°]. Microscopic plates.

**CINCHOCEROTIN**  $C_{22}H_{28}O_2$ . [130°]. Probably identical with the preceding. Deposited in tubes through which an alcoholic extract of South American calisaya bark and lime is passed (Helms, *Ar. Ph.* [3] 21, 279). Chromic acid gives acetic acid, butyric acid, and cinchoceroic acid  $C_{10}H_{14}O_2$  [72°].

**CINCHOLEPIDINE** v. (Py. 1) METHYL-QUINOLINE.

**CINCHOLINE.** Strongly basic oil. Volatile with steam. Occurs in the mother liquors from quinine. V. sol. alcohol and ether, less sol. water. The hydrochloride forms colourless

quadratic plates. The oxalate is sparingly soluble in water (Hesse, *B.* 15, 858).

**CINCHOMERONIC ACID** and **iso-cinchomeronic acid** v. PYRIDINE DI-CARBOXYLIC ACID.

**CINCHONA BARK.** *Cortex Cinchona* and *China*, *Cortex Peruvianus*, *Peruvian Bark*, *Ecorce de Quinquina*, *China rinde*.—This name is given to the bark of various species of *Cinchona*, which, with about thirty other allied genera, constitute the tribe *Cinchoneae* of the order *Rubiaceae* (v. *Pharmacographia*, f. 338). They have been long known for their antifebrile properties, which are chiefly due to the contained alkaloids, which are absent in all the allied genera, with the exception of *Remigia*, some species of which contain them.

These medicinal barks were first introduced into Europe from Peru about the year 1638, by the Countess of Chinchon, wife of the Viceroy of Peru (in whose honour the name cinchona was given to the genus by Linnaeus), and being afterwards sent over by the Jesuits, acquired great celebrity for the cure of intermittent fevers, being known by the names of Pulvis Comitesse, Jesuiticus, Patrum, &c. The cinchonas are natives of the mountain regions of South America, on the eastern slope of the Cordillera of the Andes and on the mountain ranges of Ecuador and New Granada, growing at elevations from 3,000 to 11,000 feet, no species being known to inhabit the low alluvial plains.

In 1853 an attempt was made by the Dutch Government to introduce the cultivation of cinchona into Java, but at first great difficulty was found in obtaining seeds or plants of good qualities, owing to the extreme jealousy of the natives.

In 1860 Mr. Clements Markham was sent by the Government of India to South America to collect seeds and plants, and after great difficulties he and his coadjutors succeeded in introducing the most valuable species of cinchona into India, and Mr. C. Ledger, who was then residing on the west coast of America, also succeeded in obtaining a supply of seed of the finest variety of the *Calisaya* bark.

The cultivation of the cinchonas thus introduced into the East Indies has increased to such an extent that much the greater proportion of the bark is now supplied from Ceylon, Java, and India, from whence upwards of 14,000,000 lbs. of bark were imported in 1885.

This cultivation has also been successfully introduced into Jamaica and elsewhere, in tropical regions where high mountains give the requisite elevation, and in the natural home of the genus there are now large plantations of cultivated cinchonas of the finest qualities.

• In collecting the bark in the native forests, the trees are invariably cut down, and the bark, when stripped off, dried either in the sun or on hurdles arranged over a fire in a hut.

In the plantations of cultivated bark, the system of cutting down the trees is adopted to some extent, but a far more economical method of harvesting the bark is by the process of 'renewing,' introduced by the late W. G. McIvor, by which a succession of crops of bark can be obtained from the same tree. For this purpose longitudinal incisions are made into the bark and about half the bark removed in alternate

strips, leaving the remaining bark intact, and the stem is then covered with moss. A fresh layer of bark is then formed from the cambium with surprising rapidity, and in a few months it attains the thickness of the original bark when several years old.

It is remarkable that the renewed bark is not only in most cases richer in total alkaloids than the natural bark but contains a far higher proportion of quinine, which appears to take the place of the less valuable alkaloids. Another more imperfect process adopted for renewing barks is to cut off the external layers with a spokeshave, but the results are rarely so good as in the former process, as it is essential that the liber layers of the bark should be cut through without injuring the cambium beneath, which is more difficult to do in this manner than in the other system.

Between thirty and forty species of cinchona have been described, but most of them are of no practical value. Those used in pharmacy and in the manufacture of quinine are as follows.

**I. Yellow or Calisaya Bark.** This is the most valuable of all the species of cinchona. It is found in commerce in quills formed by the contraction of the bark when drying, which are covered with a rough epidermis. It was formerly found also in flattened pieces, from which the epidermis had been removed, and which have been dried under pressure, and was then known as flat yellow bark.

**II. Crown bark. Pale bark. Loza bark** yielded by *C. officinalis* and the allied species, found in quills, with a rough blackish-brown or dark grey surface. This was formerly the chief bark used in medicine under the name of Peruvian bark. It is largely cultivated and approaches the Calisaya in richness.

**III. Red bark, Cinchona Rubra and Succirubra**, so called from the red colour of the sap and of the mature bark. Owing to the vigorous growth of this species, it has been cultivated in India to a very large extent, and has been adopted in the British Pharmacopœia for use in galenical preparation. It is less suited for the preparation of quinine, owing to the great proportion of cinchonidine that it contains.

**IV. Soft bark. Columbian and Carthagena bark**, yielded by *C. lucida* and *C. lanceolata*, imported in quills or broken pieces, with a whitish shining epidermis, which scales off easily. They vary greatly in the quantity and quality of the alkaloids.

**V. Pitayo barks**, yielded by *C. Pitayensis*, are imported in short curly pieces of a brownish colour, either bare or with a rugged whitish epidermis. They are rich in alkaloids, especially quinine and quinidine.

**VI. Cuprea bark**, yielded by *Remigia Pedunculata*. Although not a true cinchona bark, this may conveniently be included here as the only known species of any other genus that has yielded the cinchona alkaloids. It is imported in short quills and broken pieces of a deep red colour. The bark is of a very compact texture, of much higher specific gravity than the true cinchonas. It gives with ammonia a purple solution of considerable tinctorial power. It contains quinine, quinidine, cinchonine, but no cinchonidine, and an alkaloid, cupreine, dis-

covered by Paul and Cownley, which exists in the bark in a combination with quinine, previously taken for a distinct alkaloid, and designated homofluine, an allied species. *R. Purpurascens* yields no quinine, but a new alkaloid called by the discoverer, M. Arnaut, Cinchonamine.

Along with these principal species are found in commerce the bark of a great number of species of *Cinchona*, most of which contain little or no valuable alkaloid, and also barks of allied genera, especially of *Ladenbergia* and *Ecstemma*. These barks contain none of the cinchona alkaloids.

The organic constituents of cinchona bark are quinine, quinidine, cinchonine and cinchonidine, and some isomeric modifications of these bases, quinamine, uncrystallisable alkaloids, in some species aricine, paricine, and their congeners; quinic acid, quinovin and cinchotannic acid, cinchona red, colouring matter, wax, and fatty matter, a small quantity of volatile oil, along with starch, gum, and woody fibre.

The barks of some of the allied genera also contain quinovin, cinchotannic acid, and quinic acid. The ash of cinchona bark consists chiefly of calcic and potassic carbonate, containing also, besides iron, a notable quantity of manganese. For detailed analysis vide Carles, *Ph.* [3] 3, 723.

The first chemical examination of cinchona bark appears to have been made in 1785 by Hermbstädt, who obtained from it calcium quinate, which he designated as essential salt of quinine. Schneider in 1807, and Vauquelin in 1808, separated quinic acid from the calcium salt. Quinotannic acid was discovered by Deyeux in 1793, and obtained in a more definite form by Séguin in 1797. Cinchona bitter and cinchona red were obtained from red cinchona bark by Reuss in 1810. The first discovery of the alkaloids was made by Gomes of Lisbon in 1811, who appears to have obtained cinchonine in an impure state; but its true nature was not discovered till 1820, when Houton-Labillardiere drew attention to its alkaline reaction, and communicated his observations to Pelletier and Caventou, who in the same year succeeded in isolating first cinchonine, and afterwards quinine, and proved them to be true vegetable alkaloids. The isomeric modifications of these alkaloids were afterwards discovered and variously named. Pasteur (*C. R.* 36, 26; 37, 110) reduced those then known to four, quinine and its isomeride, quinidine, and cinchonine and its isomeride, cinchonidine, and also investigated the isomeric modifications of these alkaloids produced by the action of heat in strong acid solution, viz. quinicine and cinchonine. Hesse has now investigated the whole subject, and has described various alkaloids which, however, with the exception of a modification of cinchonidine named by him 'homo-cinchonine,' and the recently discovered hydroquinine, do not seem to have been isolated by other observers.

Cinchona barks are employed medicinally in the form of tinctures, fluid extracts, and infusions, and were thus used long before the discovery of the alkaloids, and, although it is to these bodies that the medicinal value is chiefly due, the cinchotannic acid and other ingredients appear also to be of medicinal value.

**Reactions of Cinchona bark.**—Most salts of the cinchona alkaloids give a purple tar when strongly heated in a test-tube, especially if they are mixed with cellulose. The same reaction is observed when a bark containing them is heated, and is very characteristic. The test was proposed by Grahe, of Kasau, in 1858. Water extracts a portion only of the alkaloidal contents of cinchona bark, and the cinchotannates of the alkaloids being more soluble in hot than in cold water, a hot infusion becomes turbid on cooling. The solution obtained by treatment with acidulated water gives the following reactions:—The alkaloids give a whitish precipitate with excess of caustic alkali, and with tannic acid, and a yellow crystalline precipitate with platinic chloride, if these precipitates are submitted to dry distillation, the characteristic odour of quinoline is observed. Of the acid constituents quino-tannic acid gives precipitates white with solution of gelatin, green with ferric salts, dirty white with tartar emetic. Quinovic acid gives, with sulphate of copper, first a green colour and then a precipitate which, when washed, has a bitter metallic taste. Quinic acid distilled with sulphuric acid and manganese peroxide yields a distillate of quinone; this test is proposed by Stenhouse (*Mém. Chem. Soc.* ii. 226) to distinguish true cinchona bark.

For the quantitative analysis of cinchona bark, various processes have been proposed, many of which give good results in practised hands, but in all of which success largely depends on details of manipulation only to be acquired by practice. The earlier processes depended on dissolving out the alkaloids with hydrochloric acid, precipitating the alkaloids by caustic alkali. A great excess of acid is required for the extraction of the whole alkaloid, and a great excess of alkali for the complete separation of the alkaloids from the cinchotannic acid which precipitates along with them by exact neutralisation. Better methods are those in which the salts of the alkaloids are decomposed in the bark by treatment with alkali, and the alkaloids then extracted by suitable solvents. De Vrij (*Pharmacographia*, p. 365, and *Ph.* [3] 4, 241) recommends to mix 20 g. of powdered bark with milk of lime (5 g. lime to 50 c.c. water), dry the mixture slowly, stirring frequently. Then boil the dry powder with 200 c.c. alcohol of S.G. 0.830, pour off and filter the solution, and boil again with 100 c.c. alcohol, throw the whole on the filter, and wash further with 100 c.c. alcohol, acidulate with dilute sulphuric acid, filter, and distil, but not to dryness (water must be added if necessary), when all the spirit is separated the aqueous solution is filtered. The filtrate and washings are reduced to 50 c.c., and while still warm treated with caustic soda in excess. After cooling, the solution is decanted off and water added before throwing it off the filter. It is then washed with the smallest possible quantity of water, pressed between folds of blotting paper, dried, and weighed. The weight is that of the total alkaloids in the bark.

The process given in the *British Pharmacopœia*, f. 111, is also a good one, it is as follows:—Mix 200 grams of the bark in fine powder with 60 grams of hydrate of calcium; moisten the powders with half an ounce of water, mix

the whole intimately; allow it to stand for an hour or two, it will then present the characters of a moist dark-brown powder, in which there should be no lumps or visible white particles. Transfer the powder to a flask, boil for half an hour with three fluid ounces of a mixture of three volumes of benzene and one of amyle alcohol, decant and filter the solution, leaving the bark in the flask, boil again with the same solvent and decant as before; repeat the third time, and finally throw the bark on the filter and wash with the solvent. The filtrates are then shaken repeatedly with water acidulated with hydrochloric acid till the alkaloids are all removed, the acid washings concentrated, and if the process given below for the separation of the alkaloids is adopted, the alkaloids are precipitated by excess of alkali.

The process given in the German *Pharmacopœia* is also efficient.

The separation of the cinchona alkaloids depends on their relative solubilities in various reagents, but in most cases these do not differ so widely as to give a perfectly satisfactory separation, and the separation is made more difficult by the tendency of the alkaloids and their salts to form more or less definite compounds with one another.

A convenient process giving fairly accurate results is as follows:—Treat the powdered mass of mixed alkaloids with ten times its weight of ether; this will dissolve the quinine and amorphous alkaloid, and small quantities only of the other alkaloids; wash the alkaloids out of this ethereal solution by excess of dilute sulphuric acid, and neutralise after heating to boiling with dilute ammonia, using no more water than is necessary; the quinine will then, on cooling, crystallise out almost entirely as sulphate, which salt is almost insoluble in a cold solution containing ammoniac sulphate. The crystals after filtration and washing with a small quantity of water are pressed between blotting paper and dried at 100°. 73.4 pts. of the anhydrous salt equal 100 of the hydrated crystals. The salt should be tested for cinchonidine, which may be present in small quantity. The alkaloids contained in the mother liquor are then precipitated by alkalis, converted into neutral acetates, and a solution of potassium iodide and a small quantity of alcohol is then added; on standing quinidine iodide will crystallise out if present. Of this salt 100 pts. equal 71.8 of the alkaloid. A solution of potassium-tartrate of sodium is then added to the mother liquor, and on agitation and standing, tartrate of cinchonidine will crystallise out if any of that alkaloid has been dissolved by the ether; 100 pts. of this salt equal 80.4 of the alkaloid. The mother liquor now contains amorphous alkali, which may be precipitated by a solution of sodic hydrate and weighed. The portion insoluble in ether must be also converted into neutral acetates, and the solution tested for quinidine by potassium iodide, a few drops of spirit being added, and for cinchonidine by potassium-tartrate of sodium as above. If a considerable proportion of this alkaloid is present it will probably contain a notable quantity of quinine, as ether fails to give a complete separation. After removal of any quinidine and cinchonidine present by those reagents, the solution contains the cin-

choline, which may be precipitated by caustic alkali and weighed. Dr. de Vrij recommends that the quinine should be precipitated from the solution of alkaloids soluble in ether, as iodo-sulphate (*Ph.* [3] 6, 461); in skilful hands this method of analysis gives accurate results. Instead of commencing the separation of the alkaloids by ether, Dr. Moens recommends that the neutral aqueous solution of the mixed alkaloids be treated with excess of solution of sodic potassium-tartrate, which throws down the whole of the quinine and cinchonidine as tartrates. The tartrate is then decomposed by alkali, and the quinine and cinchonidine separated by ether, the alkaloid dissolved in the ether being either weighed directly as quinine or preferably converted into sulphate and weighed as such. Great care must be taken in this case, to decompose the tartrate entirely, to avoid underestimating the quinine.

The method of estimating the relative proportions of quinine and cinchonidine in the precipitated tartrates by determination of the specific rotation of the polarised ray has been recommended by Drs. De Vrij and Oudemans, but no published process for bark analysis gives the tartrate obtained direct from the crude mixed alkaloids in a sufficient state of purity to give really trustworthy results by this method.

The distribution of the alkaloids in the bark has been the subject of careful observation. It was first observed by Carles (*Ph.* [3] 3, 643) that though quinine exists in all portions of the bark, it is contained in much larger proportion in the external and cortical layers than in the internal liber layers, and his observation has been confirmed by other observers.

On the other hand, the corky epidermis found in some barks, specially in certain varieties of officialis, such as the knotty bark of Jussieu does not contain alkaloid.

Alkaloids begin to form in the bark even when very young, and increase in quantity until the bark is mature, the maximum yield being attained at ages varying with the species and circumstances of growth—from five to fifteen years, or even later. The relative proportion of the different alkaloids also varies greatly in the same tree.

The increase of the dextrogyrate alkaloids, quinidine and cinchonine, in the root barks is remarkable. This is specially the case in stunted or unhealthy trees, in which the root bark is often exceptionally rich in alkaloid. As a rule a luxuriant growth of the plant is required to give the maximum of alkaloid, and therefore it is natural that manures should have a beneficial effect. Valuable experiments on this subject have been carried out by Mr. Broughton at the Government Plantation at Ootacamund (*Ph.* [3] 3, 521). He found that a great improvement in the yield of quinine was caused by the use of guano, a greater by the use of ammonia salts, but most of all by the use of farmyard manure. A series of experiments on renewed bark of *C. succirubra* in Ceylon, on the other hand, showed a maximum of improvement from the use of bones; ammonia and cattle manure producing less improvement, the different result being, no doubt, owing to a different condition of the soil. In some soils a very great improve-

ment is caused by dressings of lime. This question is one deserving of much more investigation than it has yet received.

D. H.

**CINCHONA BASES.**—Quinine, Cinchonine, Cinchonidine, and Aricine are described in separate articles. The existence of many of the following bases requires confirmation. In the names of these alkaloids *qu* is used before *i*, and *ch* before any other vowel.

**Chairamine**  $C_{20}H_{26}N_2O$ , aq. [140°]. [233° when dry] [ $\alpha$ ]<sub>D</sub> = about +100°. In the bark of *Remijia Purdieana* (Hesse, A. 225, 243). Named from *χαίρω*, because Hesse 'rejoiced' at discovering it. Slender needles (containing aq) (from dilute alcohol). Sol. ether and chloroform. Its alcoholic solution is alkaline to litmus.  $H_2SO_4$ , with or without  $MoO_3$ , forms a colourless solution, turning dark green.

**Salts.**— $B'HCl$  aq. Needles.— $B'_2H_2SO_4$  8aq. —  $(B'HCl)_2PtCl_4$  2aq.

**Conchairamine**  $C_{20}H_{26}N_2O$ , aq. EtOH. [82°–86°];  $B'$  aq [c. 110°];  $B'$  [c. 120°] [ $\alpha$ ]<sub>D</sub> (for  $B'$ ) = +68.4 in 2 p.c. alcoholic solution. In the bark of *Remijia Purdieana* (Hesse, A. 225, 216). It has three melting-points according as it is dry, with water of crystallisation, or with alcohol of crystallisation also. Colourless prisms (containing aq. EtOH) (from alcohol). Sol. ether and chloroform. Conc.  $H_2SO_4$ , with or without  $MoO_3$ , forms a brown solution turning green.

**Salts.**— $B'HCl$ . —  $(B'HCl)_2PtCl_4$  5aq. —  $B'HI$  aq.— $B'HSNC$  aq.— $B'_2H_2SO_4$  9aq.

**Methylo-iodide.**— $B'MeI$  aq. Red crystals.  $B'MeI$  3aq. Colourless crystals.

**Methylo-chloride.**— $B'MeCl$  2aq. Platino-chloride.— $(B'MeCl)_2PtCl_4$  14aq.

**Chairamidine**  $C_{20}H_{26}N_2O$ , aq. [c. 128° when dry]. [ $\alpha$ ]<sub>D</sub> = +7.3° in 3 p.c. alcoholic solution. In the bark of *Remijia Purdieana* (Hesse, A. 225, 253). Amorphous powder, insol. water, sol. ether, alcohol, benzene, and chloroform; solution in conc.  $H_2SO_4$  slowly turns green. Animal charcoal removes it from solution in acetic acid.

**Salts.**— $(B'HCl)_2PtCl_4$  5aq.—Sulphate is gelatinous.

**Conchairamidine**  $C_{20}H_{26}N_2O$ , aq. [115° when dry]. [ $\alpha$ ]<sub>D</sub> = –60° in a 3 p.c. alcoholic solution. In the bark of *Remijia Purdieana* (O. Hesse, A. 225, 256). Crystalline. V. sol. ether, alcohol, chloroform, benzene, and acetone. Its alcoholic solution is neutral to litmus. In conc.  $H_2SO_4$ , with or without  $MoO_3$ , the solution is dark green.

**Salts.**—Well crystallised.— $B'HCl$  3aq. —  $(B'HCl)_2PtCl_4$  5aq.— $B'_2H_2SO_4$  14aq.

**Cinchamidine**  $C_{20}H_{26}N_2O$ . [230°]. [ $\alpha$ ]<sub>D</sub> = –98.4. Occurs in the mother-liquors from homocinchonidine (Hesse, B. 14, 1683; cf. Forst a. Böhringer, B. 14, 1270; 15, 520). Colourless plates, needles, or prisms. Sol. alcohol and chloroform, sl. sol. ether, insol. water. Has an alkaline reaction.

**Salts.**— $B'HCl$  2aq: trimetric prisms. —  $(B'HCl)_2PtCl_4$  3aq: yellow amorphous pp. —  $B'_2H_2Cl_2PtCl_4$ : orange plates.—Tartrate  $B'_2C_4H_4O_6$  2aq: colourless prisms, sl. sol. cold water.

**Cinchonamine**  $C_{19}H_{25}N_2O$ . [194°] (A.); [185°] (H.). [ $\alpha$ ]<sub>D</sub> = +121° (1 pt. base in 50 pts. of 97 p.c. alcohol at 15°).

**Occurrence.**—In *Cinchona Purdieana* (A.

litmus.  $\text{AuCl}_3$  gives a yellowish pp. which soon turns purple. Paper moistened with an acid solution of the sulphate is turned green, and finally blue, by  $\text{Cl}_2\text{O}_7$ .

**Salts.**— $\text{B}^+\text{HCl}$  aq: prisms.— $\text{B}^+\text{H}_2\text{PtCl}_6$  2aq.— $\text{B}^+\text{HClO}_4$ .— $\text{B}^+\text{HBr}$  aq.— $\text{B}^+\text{HI}$ . S. 1.4 at  $16^\circ$ .— $\text{B}^+\text{HNO}_3$ .

**Quinamidine**  $\text{C}_{10}\text{H}_{14}\text{N}_2\text{O}_2$ . [93°].  $[\alpha]_D = 4.5^\circ$  (in a 2 p.c. alcoholic solution). Formed by the action of acids upon quinamine (Hesse, A. 207, 299). Nodules; v. c. sol. alcohol. Not ppd. by  $\text{NH}_3$  from acid solutions, but ppd. by  $\text{NaOH}$ .  $\text{AuCl}_3$  gives a purple colour in solutions of its hydrochloride.— $\text{B}^+\text{HCl}$  aq.— $\text{B}^+\text{H}_2\text{PtCl}_6$  6aq.— $\text{B}^+\text{HBr}$  aq.—Oxalate  $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$  4aq.

**Quinamine**  $\text{C}_{10}\text{H}_{14}\text{N}_2\text{O}_2$ . [109°].  $[\alpha]_D = 3.8^\circ$  (in a 2 p.c. alcoholic solution). Formed by heating quinamine with dilute acids at  $130^\circ$  (Hesse, A. 207, 303). Amorphous, but gradually becomes crystalline. V. c. sol. alcohol. Dextrorotatory.— $\text{B}^+\text{H}_2\text{PtCl}_6$  3aq.

**Protoquinamine**  $\text{C}_{10}\text{H}_{14}\text{N}_2\text{O}_2$ . Formed by heating dry quinamine acid sulphate at  $130^\circ$  (Hesse, A. 207, 305). Amorphous brown base.— $\text{B}^+\text{H}_2\text{PtCl}_6$ .

**Apoquinamine**  $\text{C}_{10}\text{H}_{12}\text{N}_2\text{O}_2$ . [114°]. Formed by boiling quinamine with excess of  $\text{HCl}$  (S.G. 1.125) for 3 minutes (Hesse, A. 207, 294). The alcoholic solution is inactive and neutral to litmus: the hydrochloride is levorotatory.— $\text{B}^+\text{HCl}$  aq.— $\text{B}^+\text{H}_2\text{PtCl}_6$  2aq.— $\text{B}^+\text{HNO}_3$ .—Oxalate  $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$  aq.—Tartrate  $\text{B}^+\text{C}_4\text{H}_4\text{O}_6$  3aq.

**Acetyl derivative**  $\text{C}_{10}\text{H}_{12}\text{N}_2\text{O}_2\text{Ac}$ . Amorphous.— $\text{B}^+\text{H}_2\text{PtCl}_6$  2aq.

**Conquinamine**  $\text{C}_{10}\text{H}_{12}\text{N}_2\text{O}_2$ . [123°].  $[\alpha]_D = 205^\circ$  (in a 2 p.c. alcoholic solution). S. (91 p.c. alcohol)  $13.5$  at  $19^\circ$ ; S. (ether)  $13.5$  at  $15^\circ$ ; S. (benzene)  $24.4$  at  $18^\circ$ ; S. (CS<sub>2</sub>)  $6.05$  at  $18^\circ$ . Occurs in the bark of *C. succirubra* and *rosulenta*. It is best separated from quinamine through the greater solubility of its salts (Oudemans, A. 209, 38; Hesse, A. 203, 62).

**Properties.**—Long prisms or pyramids. It resembles quinamine in its reactions with  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$ . Gold chloride gives a golden pp. followed by a purple colouration. Heating with  $\text{HCl}$  forms apoquinamine  $\text{C}_{10}\text{H}_{12}\text{N}_2$ .

**Salts.**— $\text{B}^+\text{HCl}$ : octahedra, m. sol. water;  $[\alpha]_D = 205^\circ$ .— $\text{B}^+\text{H}_2\text{PtCl}_6$  3aq (O.).— $\text{B}^+\text{H}_2\text{PtCl}_6$  aq (H.).— $\text{B}^+\text{HClO}_4$ .— $\text{B}^+\text{HBr}$ .— $\text{B}^+\text{HI}$ . S.  $9.4$  at  $16^\circ$ .— $\text{B}^+\text{HNO}_3$ .— $\text{B}^+\text{H}_2\text{SO}_4$ .—Formate  $\text{B}^+\text{CHO}_2$ : monoclinic crystals.—Acetate  $\text{B}^+\text{HOAc}$ : dimetric crystals.—Oxalate  $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$  3aq.—Quinate  $\text{B}^+\text{C}_4\text{H}_4\text{O}_6$  2aq: prisms.

**Quinidine**  $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2$ . **Conquinine**. [168°].  $[\alpha]_D = 236.8 - 8p$  (in a p.p.c. alcoholic solution). S.  $.05$  at  $16^\circ$ ; S. (ether)  $3$  at  $10^\circ$ . Occurs in the bark of *Cinchona Calisaya*, *C. pitayensis*, and other species of *Cinchona* (van Heijningen, A. 72, 302; Pasteur, C. R. 36, 20; Stenhouse, A. 129, 15; Hesse, A. 146, 357; 166, 232; 174, 338; 176, 225; 182, 163; B. 10, 2154; 12, 425; Oudemans, A. 182, 53). By adding  $\text{NaOH}$  to the mother-liquors from which quinine sulphate has separated crude quinidine is ppd. Pure quinidine may be isolated from this by means of its iodide. Prisms (containing  $2\frac{1}{2}$  aq) (from alcohol), rhombohedra (containing 2aq) (from ether), or laminae (containing  $1\frac{1}{2}$  aq) (from water). Its solution in dilute  $\text{H}_2\text{SO}_4$  fluoresces blue.

Chlorine-water and  $\text{NH}_3$  give a green colour. Dilute  $\text{H}_2\text{SO}_4$  at  $100^\circ$  changes it to quinicina. Conc.  $\text{HCl}$  converts it on heating into apoquinidine and apoquinidine chlorohydrate. It is a febrifuge. It crystallises in trimetric forms with various alcohols:  $\text{B}^+\text{MeOH}$ ;  $\text{B}^+\text{EtOH}$ ;  $\text{B}^+\text{PrOH}$ ;  $\text{B}^+\text{C}_4\text{H}_9\text{OH}$ ; and  $\text{B}^+\text{C}_6\text{H}_5(\text{OH})_2$  (MgHus, B. 19, 1773).

**Salts.**— $\text{B}^+\text{HCl}$  aq. S. 1.6 at  $10^\circ$ ;  $[\alpha]_D = 212 - 2.56p$  (in a p.p.c. alcoholic solution).— $\text{B}^+\text{H}_2\text{Cl}_2$  aq:  $[\alpha]_D = 250^\circ$  in a 2 p.c. aqueous solution.— $\text{B}^+\text{H}_2\text{ZnCl}_4$ .— $\text{B}^+\text{H}_2\text{ZnCl}_4$ .— $\text{B}^+\text{H}_2\text{HgCl}_4$ .— $\text{B}^+\text{H}_2\text{PtCl}_6$  aq.— $\text{B}^+\text{H}_2\text{PtCl}_6$  3aq.— $\text{B}^+\text{H}_2\text{AuCl}_4$ .— $\text{B}^+\text{HBr}$ . S.  $.5$  at  $14^\circ$  (de Vrij, J. Ph. [3] 32, 328).— $\text{B}^+\text{HI}$ . S.  $.08$  at  $15^\circ$ .— $\text{B}^+\text{H}_2\text{I}_2$  3aq. S.  $1.1$  at  $15^\circ$ .— $\text{B}^+\text{HNO}_3$ . S.  $1.2$  at  $45^\circ$ .— $\text{B}^+\text{AgNO}_3$ .— $\text{B}^+\text{H}_2\text{SO}_4$  2aq. S.  $1$  at  $15^\circ$ .  $[\alpha]_D = 184^\circ$  in a 3 p.c. solution in chloroform.— $\text{B}^+\text{H}_2\text{SO}_4$  4aq. S.  $11.5$  at  $10^\circ$ .— $\text{B}^+\text{H}_2\text{SO}_4\text{H}_2\text{I}$  (Jørgensen, J. pr. [2] 14, 356; 15, 67).— $\text{B}^+(\text{H}_2\text{SO}_4)_2\text{H}_2\text{I}$ .— $\text{B}^+(\text{H}_2\text{SeO}_4)_2\text{H}_2\text{I}$ .— $\text{B}^+(\text{H}_2\text{SeO}_4)_2\text{H}_2\text{I}$ .— $\text{B}^+(\text{H}_2\text{SeO}_4)_2\text{H}_2\text{I}$ .— $\text{B}^+\text{H}_2\text{CrO}_4$  6aq: large yellow plates (Hesse, A. 243, 144).—Oxalate  $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$  aq. S.  $.66$  at  $15^\circ$ .—Succinate  $\text{B}^+\text{C}_4\text{H}_4\text{O}_6$  2aq.—Tartrate  $\text{B}^+\text{C}_4\text{H}_4\text{O}_6$  aq. S.  $.26$  at  $15^\circ$ .—Acid tartrate  $\text{B}^+\text{C}_4\text{H}_4\text{O}_6$  3aq. S.  $.25$  at  $10^\circ$ .— $\text{B}^+\text{C}_6\text{H}_5(\text{SbO})_2$  4aq. S.  $.18$  at  $10^\circ$ .

**Acetyl derivative**  $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2\text{Ac}$ .  $[\alpha]_D = 128^\circ$  in a 2 p.c. alcoholic solution at  $15^\circ$ . Amorphous.— $\text{B}^+\text{H}_2\text{PtCl}_6$  3aq.— $\text{B}^+\text{H}_2\text{AuCl}_4$  2aq.

**Methylo-iodide**  $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2\text{MeI}$ : needles (Stahlschmidt, A. 90, 221).— $\text{B}^+\text{MeI}$ , [165°] (Jørgensen, J. pr. [2] 3, 153).

**Ethyl-iodide**  $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2\text{EtI}$  (Stenhouse, A. 129, 20).— $\text{B}^+\text{EtI}$  aq (Howard, C. J. 26, 1183).— $\text{B}^+\text{EtCl}$  aq.— $\text{B}^+\text{EtHPtCl}_6$ .— $\text{B}^+\text{Et}_2\text{H}_2\text{SO}_4$ .

**Quinidine chloride**  $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2\text{Cl}$ . **Conquinine chloride**. [132°]. Formed by the action of  $\text{PCl}_5$  upon the hydrochloride of quinidine (conquinine) (Comstock & Königs, B. 18, 1223). Colourless crystals. V. sol. alcohol, benzene, and chloroform, sl. sol. ligroin and dry ether. By boiling with alcoholic  $\text{KOH}$  it is converted into quiniene  $\text{C}_{20}\text{H}_{22}\text{N}_2\text{O}$ .

**Apoquinidine**  $\text{C}_{20}\text{H}_{22}\text{N}_2\text{O}$ . **Apoconquinine**. [137°].  $[\alpha]_D = 155^\circ$  (in a 2 p.c. alcoholic solution). Formed, together with  $\text{MeCl}$ , by heating quinidine with conc.  $\text{HCl}$ . White, amorphous powder (containing 2aq). Sol. alcohol and ether,  $[\alpha]_D = 153.3p = 2$ ,  $t = 15^\circ$  in 97 p.c. alcohol. The solution in dilute  $\text{H}_2\text{SO}_4$  does not fluoresce, and gives no green colour with  $\text{Cl}$  and  $\text{NH}_3$  (Hesse, A. 205, 326).

**Hydrochloride**: acicular crystals, v. sol. water.— $\text{B}^+\text{H}_2\text{PtCl}_6$  3aq: yellow flocculent pp.

**Diacetyl derivative**  $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2\text{Ac}_2$ .  $[\alpha]_D = 40.4^\circ$  in a 2 p.c. solution in 97 p.c. alcohol at  $15^\circ$ . Its sulphate fluoresces blue, and gives a green colour with  $\text{Cl}$  and  $\text{NH}_3$ .— $\text{B}^+\text{H}_2\text{PtCl}_6$  2aq: golden crystalline pp.

**Apoquinidine chlorohydrate**  $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2$ . Formed by heating quinidine or apoquinidine with fuming  $\text{HCl}$  at  $150^\circ$ . Crystalline (with 2aq) or amorphous when anhydrous [164°]. Sol. ether and alcohol.  $[\alpha]_D = 203.7^\circ$  ( $p = 2$ ,  $t = 15.97^\circ$  v.p.c. alcohol). Does not give a green colour with  $\text{Cl}$  and  $\text{NH}_3$ .— $\text{B}^+\text{H}_2\text{Cl}$ .— $\text{B}^+\text{H}_2\text{PtCl}_6$  4aq.

**Diacetyl derivative**  $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2\text{Ac}_2$ . [168°]. Gives no green colour with  $\text{Cl}$  and  $\text{NH}_3$ .  $[\alpha]_D = 95^\circ$  in a 2 p.c. solution in dilute  $\text{HCl}$ .— $\text{B}^+\text{H}_2\text{PtCl}_6$  3aq.

**Iso-quinidias**  $C_{20}H_{24}N_2O_7$ . Formed by dissolving quinidine in conc.  $H_2SO_4$  (Hesse, A. 243, 149). Long needles (from ether).— $B''H_2SO_4$  8aq: needles.— $B''H.PtCl_5$  3aq: yellow flocculent pp.

**Quinine**  $C_{20}H_{24}N_2O_6$ . *Quinine*. [81°]. Formed by treatment of quinine or quinidine with  $PCl_5$  followed by alcoholic KOH (Comstock a. Königs, B. 17, 1989; 18, 1223). Trimetric crystals (containing 2aq),  $a:b:c = .5322:1: .6642$ . The solution in dilute  $H_2SO_4$  shows a greenish-blue fluorescence. By heating with  $HBr$  (or  $HCl$ ) it is converted into apoquinine  $C_{18}H_{22}N_2O_4$ .

Salts.— $B''H_2Cl_2.ZnCl_2$  2aq: trimetric prisms,  $a:b:c = .3424:1: .4964$ .—The tartrate is sl. sol. cold water, and well crystallised.

**Dibromide**  $C_{20}H_{22}Br_2N_2O_6$ . Obtained by addition of bromine to quinine. By boiling with alcoholic KOH it is converted into dehydroquinine  $C_{20}H_{18}N_2O_6$ . The *hydrobromide*  $B''H_2Br_2$  2aq forms yellow crystals, sl. sol. alcohol, aqueous  $HBr$  or cold water (Comstock a. Königs, B. 20, 251b).

**Dehydroquinine**  $C_{20}H_{18}N_2O_6$ . Formed by boiling quinine-di-bromide with alcoholic KOH. Colourless crystals (with 3aq). V. sol. alcohol and ether, nearly insol. water. Dissolves in very dilute  $H_2SO_4$  with a strong green-blue fluorescence. Gives the quinine reaction with chlorine and ammonia (Comstock a. Königs, B. 20, 2517).

**Quinine**  $C_{20}H_{24}N_2O_6$ . [60°].  $[\alpha]_D = 44^\circ$  (in a 2 p.c. chloroform solution). Occurs in cinchona bark (Howard, C. J. 24, 61; 25, 101). Formed by heating the sulphate of quinine or quinidine with  $H_2SO_4$  at  $130^\circ$  (Pasteur, C. R. 37, 110; Hesse, A. 178, 245). Formed also by heating quinine or quinidine with glycerin at  $200^\circ$  (Hesse, A. 166, 277). Oil, which slowly solidifies. Sl. sol. water, v. sol. alcohol and ether. Its alcoholic solution is alkaline to litmus.  $Cl$  and  $NH_3$  give a green colour. Its solution in dilute  $H_2SO_4$  is not fluorescent.

Salts.— $B''H.PtCl_5$  2aq. —  $B''HI$  aq. —  $B''H_2SO_4$  3aq.—Oxalate  $B''H_2C_2O_4$  9aq. S. 4 at  $16^\circ$ .—Acid tartrate  $B''H_2C_4H_4O_6$  6aq. [100°]. Sulphocyanide  $B''HSCy$  3aq.

**Apoquinine**  $C_{18}H_{22}N_2O_4$ . *Apoquinine*. [246°]. Formed by heating quinine with aqueous  $HBr$  (S.G. 1.5) at about  $180^\circ$  (Comstock a. Königs, B. 18, 1226). Colourless crystals. V. sol. alcohol, sl. sol. water, ether, and benzene. It dissolves in aqueous acids and alkalis, forming yellow solutions. The sulphate is sparingly soluble. The hydrobromide forms small yellow crystals.

**Cupreine**  $C_{20}H_{22}N_2O_5$ . [198°]. (Paul a. Cownley, Ph. [3] 15, 221; Hesse, A. 230, 55). Occurs in cuprea bark. The crude quinine sulphate from such bark is dissolved in aqueous  $H_2SO_4$ , excess of  $NaOH$  is added, and the ppd. quinine shalen out with ether. The aqueous liquid is warmed and neutralised with  $H_2SO_4$ . Cupreine sulphate then separates (Hesse, A. 226, 240; 230, 57).

**Properties**.—Concentric prisms, containing 2aq (from ether). From alcohol it separates in the dry form. V. sl. sol. ether or chloroform, more sol. alcohol. The alcoholic solution is alkaline to litmus, gives a dark reddish brown colour with  $Fe_2Cl_6$ , and a deep green with chlorine water, followed by ammonia. The solution in dilute  $H_2SO_4$  does not fluoresce, but gives with  $NH_3$  a pp. slightly soluble in excess of  $NH_3$ ,

and easily soluble in  $NaOH$ . Ether extracts the base from the ammoniacal solution, but not from the solution in  $NaOH$ . It rotates light to the right almost as strongly as quinine. Its neutral salts form yellow solutions; its acid salts are colourless.  $HCl$  (S.G. 1.125) at  $140^\circ$  converts cupreine into apoquinine, no  $MeCl$  being evolved.

Salts.—(Hesse, A. 230, 59.)  $B''H_2SO_4$  6aq.  $B''H_2SO_4$  aq. —  $B''HCl$  aq. —  $B''(HCl)_2$ . —  $(B''HCl)_2PtCl_5$  4aq. —  $B''(HCl)_2PtCl_5$  aq. —  $B''H_2C_2O_4$  2aq. The base combines with  $NaOH$  and  $KOH$  (1 mol.), but not with  $NH_3$ . It also forms calcium, lead, and silver compounds.

**Diacetyl derivative**  $C_{20}H_{20}Ac_2N_2O_8$  [88°]. Salt.— $C_{20}H_{20}Ac_2N_2O_8.H.PtCl_5$  3aq.

**Mono-methylo-compounds**.— $B''MeI$  is thrown down on adding  $MeI$  to alcoholic cupreine solution. Colourless needles, very sparingly soluble in alcohol or water, insoluble in ether. Very soluble both in acids and alkalis.— $B''MeCl$ . —  $B''MeCl.HCl.PtCl_5$  2aq. —  $(B''Me)_2SO_4$ . On adding baryta to a solution of the methylo-sulphate, and evaporating the filtrate, the hydroxide,  $(B''Me)OH$ , remains as a yellow amorphous residue. It has a bitter taste, is insoluble in ether, but very soluble in water. With a little bleaching-powder and ammonia it gives a green colour; if more bleaching-powder is used the colour is red.

**Di-methylo-compounds**  $B''2MeI$  5aq forms orange plates (from water), soluble in acids, alkalis, and alcohol (though not in water). The corresponding hydroxide is only known in solution.

**Hydrocupreine**  $C_{19}H_{22}N_2O_7$ . [169°]. Formed by heating hydroquinine sulphate with  $HClAq$  (S.G. 1.125) (Hesse, A. 241, 279). Microcrystalline powder (containing 2aq). Alkaline to litmus. A solution of its sulphate does not fluoresce.— $B''H_2SO_4$ : small needles, v. sl. sol. water and alcohol.— $B''_2C_2H_4O_2$  2aq.— $B''H_2Cl_2$  aq. —  $B''H.PtCl_5$ .

**Homoquinine**. This substance, obtained from *China cuprea* (the bark of *Remijia pedunculata*) (Howard a. Hodgkin, C. J. 41, 66), is also formed by adding sodium cupreine to quinine hydrochloride (Hesse, A. 230, 70). It is therefore a molecular compound of quinine and cupreine,  $C_{20}H_{24}N_2O_6.C_{19}H_{22}N_2O_7$  4aq.

**Cuscamine**. [218°]. An alkaloid in the bark of *Cinchona Pelletierana* (Hesse, A. 200, 304). Prisms; v. sol. ether, m. sol. alcohol.

**Cusconine**  $C_{20}H_{24}N_2O_7$  2aq. [110°]. S. (ether) 3 at  $18^\circ$ .  $[\alpha]_D = -54^\circ$  (in a 2 p.c. alcoholic solution). Occurs together with aricine in the bark of *C. cuprea* (Hesse, A. 185, 320; Paul a. Cownley, Ph. [3] 12, 497). Plates (containing 2aq) (from ether). Its acid solutions do not fluoresce. Levorotatory. Conc.  $HNO_3$  turns it dark green.  $B''HHgCl_2$  2aq. —  $B''H_2PtCl_5$  5aq: amorphous. —  $B''H_2SO_4$  2aq.— $B''HSCy$  2aq: yellow powder.

**Cusconine**  $C_{20}H_{24}N_2O_7$  aq. [144°]. When dry [c. 208°].  $[\alpha]_D = +40.8^\circ$  at  $15^\circ$  in 2 per cent. alcoholic solution. In bark of *Remijia Purdiana* (cuprea bark) (O. Hesse, A. 225, 234). Monoclinic crystals (containing aq). Sl. sol. alcohol, but ppd. by water from that solution. V. sol. benzene, ether, and chloroform; sl. sol. petroleum. Its alcoholic solution is neutral to litmus. At  $150^\circ$  it partly changes to an amorphous variety. It forms no acetyl derivative with  $Ac_2O$ . Conc.

HNO<sub>3</sub> added to its solution in acetic acid or HCl gives a splendid dark-green colour. Conc. H<sub>2</sub>SO<sub>4</sub> forms a blue-green solution, turned olive-green on warming.

**Salts.**—Mostly gelatinous.—(B'HCl)<sub>2</sub>PtCl<sub>6</sub> 5aq.—B'<sub>2</sub>H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>.B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub>. Prisms.

(a) *Methylo-iodide* B'MeI. Crystalline powder: hardly sol. alcohol, sol. boiling water. From it may be obtained: B'MeCl, needles; (B'MeCl)<sub>2</sub>PtCl<sub>6</sub>, amorphous; (B'Me)<sub>2</sub>SO<sub>4</sub>; and B'MeOH, which when dry melts at [202°].

(β) *Methylo-iodide* B'MeI. Gelatinous. V. sol. alcohol. From it may be obtained: B'MeCl, amorphous; (B'MeCl)<sub>2</sub>PtCl<sub>6</sub> 5aq, amorphous; (B'Me)<sub>2</sub>SO<sub>4</sub>; and B'MeOH 2½aq.

**Cuscoquinine.** An amorphous alkaloid in Cusco bark (Hesse, A. 200, 303).

**Concusquinine** C<sub>20</sub>H<sub>26</sub>N<sub>2</sub>O<sub>8</sub>. [124°]. A slightly dextrorotatory amorphous alkaloid, said to occur in cupra bark (Hesse, B. 16, 62). —B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>.

**Hydroquinine** C<sub>20</sub>H<sub>26</sub>N<sub>2</sub>O<sub>8</sub>. [168°]. [α]<sub>D</sub> = -142.2° (p = 2.4 in 95 p.c. alcohol at 20°; but [α]<sub>D</sub> = -227.1° in dil. HCl. Discovered by Hesse (B. 15, 856) in mother-liquors of quinine sulphate.

**Preparation** (Hesse, A. 241, 255).—The mother-liquor from quinine monosulphate is treated with successive quantities of sulphuric acid until a neutral salt is obtained containing over 80 p.c. of hydroquinine sulphate. The quinine is then removed with KMnO<sub>4</sub> and after neutralisation with NaOHAq the hydroquinine is extracted with ether, benzene, or chloroform.

**Properties.**—Can be obtained by neutralising the solution in dilute acid with NaOHAq as an amorphous pp. having the composition C<sub>20</sub>H<sub>26</sub>N<sub>2</sub>O<sub>8</sub> 2aq. Crystallises from chloroform in concentric grouped needles. V. sol. alcohol, chloroform, ether, benzene, and CS<sub>2</sub>, m. sol. ammonia, sl. sol. water, insol. NaOHAq. Solution in dilute H<sub>2</sub>SO<sub>4</sub> shows blue fluorescence, and gives the same reactions as quinine with Cl and ammonia, but decolourises KMnO<sub>4</sub> very slowly. Alkaline reaction, bitter taste. Heated with HCl it yields hydrocupreine.

**Salts.**—B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub> 6aq: short white prisms; v. sol. alcohol and hot water, sl. sol. cold water, insol. ether. S. 287 at 15°. [α]<sub>D</sub> = -193.1°. —B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub> 3aq: long thin needles; v. sol. water and alcohol, m. sol. acetone. Heated to 120° it gives off water, and to 140° yields hydroquinine sulphate.—B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub> 2aq.—B'HCl 2aq: long flat prisms; v. sol. water and alcohol, insol. ether.—B'<sub>2</sub>PtCl<sub>6</sub>H<sub>2</sub> 3aq: yellow amorphous pp.; v. sl. sol. water and alcohol.—B'<sub>2</sub>PtCl<sub>6</sub>H<sub>2</sub> 2aq.—B'<sub>2</sub>AsCl<sub>6</sub>H<sub>2</sub> 2aq(?): yellow amorphous pp.—B'<sub>2</sub>ZnCl<sub>2</sub>HgCl<sub>2</sub>: small colourless flat needles.—B'BrH 2aq.—B'(BrH)<sub>2</sub> 3aq: B'III: oil, becoming solid but not crystallising.—B'(IH)<sub>2</sub> 4aq: shining yellow needles.—B'HI<sub>2</sub> 2aq: metallic, dichroic flat needles.—B'HCNS: a resin; m. sol. water.—B'C<sub>2</sub>H<sub>2</sub>O<sub>4</sub> 5aq. [100°]: small colourless needles; v. sol. water and alcohol.—Benzonate B'C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>: small needles; v. sol. alcohol, sl. sol. water.—Salicylate B'C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>: small colourless needles; v. sl. sol. cold water, m. sol. hot water, v. sol. alcohol.—Piperonylate B'C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>. —B'<sub>2</sub>C<sub>2</sub>O<sub>4</sub>H<sub>2</sub> 6aq: long shining needles; insol. ether, v. sol. hot, sl. sol. cold, water, v. sol. alcohol. S. 213 at 15°. —B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub> 2aq: thick colourless prisms; m. sol. hot water, alcohol, v. sol. chloro-

form-alcohol, sl. sol. water. S. 188 at 17°. [α]<sub>D</sub> = -176.35° (cf. Ph. [3] 16, 1025).—Citrate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub> 10aq: small white needles; v. sol. boiling, sl. sol. cold, water.—B'<sub>2</sub>PO<sub>4</sub>H<sub>2</sub> 7aq: small white needles; sl. sol. water.—B'<sub>2</sub>(AsO<sub>4</sub>H<sub>2</sub>)<sub>2</sub> 10aq: long white needles.—B'<sub>2</sub>CrO<sub>4</sub>H<sub>2</sub> 6aq: long golden needles; m. sol. hot, sl. sol. cold, water, v. sl. sol. chloroform.

**Combinations.**—1. With cupreine C<sub>20</sub>H<sub>26</sub>N<sub>2</sub>O<sub>8</sub>.C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub> 2aq: long shining needles grouped concentrically.—2. With quinidine C<sub>20</sub>H<sub>26</sub>N<sub>2</sub>O<sub>8</sub>.C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub> 2aq: white needles.—3. With anethol (C<sub>10</sub>H<sub>18</sub>N<sub>2</sub>O<sub>2</sub>).C<sub>10</sub>H<sub>18</sub>O 2aq. Large shining dimetric prisms. V. sol. hot alcohol, ether; sl. sol. cold alcohol; insol. water. Decomposes at 120° into hydroquinine, anethol, and water.—4. Also forms compounds with hydroquinidine, cinchonidine, hydrocinchonidine, and homocinchonidine, but not with cinchonine or hydrocinchonine.

**Methylo- compounds** B'MeI EtOH. Pale yellow prisms. [218°]. V. sol. hot, m. sol. cold alcohol, insol. water.—B'MeCl 2aq [168°]. —B'MeH<sub>2</sub>PtCl<sub>6</sub> 2aq: orange-red needles.—B'<sub>2</sub>Me<sub>2</sub>PtCl<sub>6</sub>: pale-yellow needles; m. sol. alcohol and water.—B'MeOH: resin; insol. ether and chloroform; v. sol. alcohol and water. Absorbs CO<sub>2</sub>.

**Acetyl derivative** C<sub>20</sub>H<sub>26</sub>N<sub>2</sub>O<sub>8</sub>Ac. [c. 40°]. V. sol. ether, alcohol, benzene, acetone, and acids; sl. sol. water, and NH<sub>3</sub>. [α]<sub>D</sub> = -73.9° in 3 molecules HClAq p = 3, t = 15°. —(C<sub>20</sub>H<sub>26</sub>AcN<sub>2</sub>O<sub>8</sub>)PtCl<sub>6</sub>H<sub>2</sub> 2aq: powdery pp.; sl. sol. dil. HCl and water.—(C<sub>20</sub>H<sub>26</sub>AcN<sub>2</sub>O<sub>8</sub>)SO<sub>4</sub>H<sub>2</sub> 9aq: long needles; v. sol. hot water, alcohol, sl. sol. cold water, insol. ether.

**Sulphonic acid.**—Strong H<sub>2</sub>SO<sub>4</sub> at ordinary temperatures forms hydroquinine sulphonic acid C<sub>20</sub>H<sub>26</sub>N<sub>2</sub>O<sub>8</sub>.SO<sub>3</sub>H 4aq [239°]; insol. ether, chloroform; sl. sol. NH<sub>3</sub> and NaOHAq.—(C<sub>20</sub>H<sub>26</sub>N<sub>2</sub>O<sub>8</sub>.SO<sub>3</sub>H)PtCl<sub>6</sub>H<sub>2</sub> 8aq: pale yellow needles.

**Hydroquinine** C<sub>20</sub>H<sub>26</sub>N<sub>2</sub>O<sub>8</sub>. Formed by fusing hydroquinine sulphate at 140° (Hesse, A. 241, 273). Yellow resin. V. sol. ether, alcohol, chloroform and dilute acids. Solution in dilute H<sub>2</sub>SO<sub>4</sub> is intensely yellow, addition of chlorine-water and ammonia gives a yellowish green colouration. More easily acted on by KMnO<sub>4</sub> than hydroquinine.—**Salts.**—Neutral sulphate; white needles, v. e. sol. alcohol and water.—B'<sub>2</sub>PtCl<sub>6</sub>H<sub>2</sub> 3aq: pale yellow flocculent pp. changing to orange-coloured crystals insol. water, sl. sol. dilute HCl.

**Hydroquinidine** C<sub>20</sub>H<sub>26</sub>N<sub>2</sub>O<sub>8</sub>. *Hydroquinidine*. [167°]. Occurs in crude quinidine, and obtained therefrom by treatment in acid solution with KMnO<sub>4</sub> which does not attack hydroquinidine (Forst a. Böhringer, B. 14, 1954; 15, 519, 1656; Hesse, B. 15, 854). Needles or tables. M. sol. ether, v. sol. alcohol and chloroform. The alcoholic solution is alkaline to litmus. Its solution in dilute H<sub>2</sub>SO<sub>4</sub> shows blue fluorescence. It is dextrorotatory. Chlorine-water and NH<sub>3</sub> give a green colour. Chronic mixture forms quinic acid.

**Salts.**—B'HCl: soluble prismatic tables.—B'Br: plates, sl. sol. cold water.—B'HI<sub>2</sub>PtCl<sub>6</sub> 2aq. B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub> 12aq.—B'III.—B'HI<sub>2</sub> 3aq: large orange soluble crystals.—Tartrate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>4</sub> 2aq: glistening soluble prisms.—**Acid tartrate**

Chloride  $BHCl$ . [168°]. Slender needles (containing aq.).— $BH_2PtCl_2$  3aq.

**Methylo-iodide**  $C_{19}H_{21}MeN_2O.MeI$  2aq: crystals.

**Methylo-di-iodide**  $C_{19}H_{21}MeN_2O.HI.MeI$ : large prisms.

**Ethyl-cinchonidine**  $C_{22}H_{29}N_2O$ . [90°]. Colourless needles. V. sol. alcohol and ether, insol. water. Prepared by the action of aqueous KOH on the iodide (Claus a. Dannenbaum, *B.* 18, 2189).

**Salts**.— $BHCl$  3aq: cubes; v. sol. water and alcohol (Howard, *C. J.* 26, 1181; Claus, *B.* 14, 1922). Levorotatory.— $BHBr$  aq.— $BHI$ . [261°]. From cinchonidine and  $EtI$ . Needles.  $BH_2$ — $BHCy$ . [140°]. Slender needles, v. sol. water (Claus a. Merck, *B.* 16, 2745).— $B^*H_2Cl_2PtCl_2$  aq: crystalline pp.

**Methylo-iodide**  $BMeI$ . Colourless needles. Decomposes at 257°.

**Ethyl-iodide**  $BEtI$ . Resembles the methylo-iodide; on treatment with KOH it gives a di-ethyl-cinchonidine.

**Ethyl-di-iodide**  $C_{19}H_{21}EtN_2O.HI$  2aq. [255°]. Golden crystals.

**Isoamyl-cinchonidine**  $C_{19}H_{21}(C_4H_9)_2N_2O$ . Resin.— $BH_2PtCl_2$  2aq (Claus a. Weller, *B.* 14, 1922).

**Di-bromo-cinchonidine**  $C_{19}H_{21}Br_2N_2O$ . From cinchonidine in  $CS_2$  and  $Br$  (Skalweit, *A.* 172, 108).— $BH_2Br_2$ : needles, v. sol. alcohol.

**Di-oxy-cinchonidine**  $C_{19}H_{21}(OH)_2N_2O$ . From the preceding by long boiling with alcoholic KOH (S.). Ramified crystals.— $B^*H_2SO_4$  2aq: plates.— $BH_2SO_4$ — $B^*H_2PtCl_2$ .

**Apocinchonidine**  $C_{19}H_{21}N_2O$ . [225°]. [ $\alpha$ ]<sub>D</sub> = -129° in a  $\frac{1}{2}$  p.c. alcoholic solution at 15°. Formed by heating cinchonidine with  $HCl$  (6 pts. of S.G. 1.105) at 150° (Hesse, *A.* 205, 327). Small plates (from alcohol). Levorotatory. Its acid solutions do not fluoresce.— $BH_2PtCl_2$  2aq.

**Acetyl derivative**  $C_{19}H_{21}AcN_2O$ . [ $\alpha$ ]<sub>D</sub> = -62° in a 2 p.c. alcoholic solution at 15°.— $B^*H_2PtCl_2$  2aq.— $B^*(HAcCl)_2$  aq.

**Apocinchonidine chlorohydrate**  $C_{19}H_{21}ClN_2O$ . [200°]. [ $\alpha$ ]<sub>D</sub> = -142° in a 2 p.c. solution of dilute  $HCl$  (containing 3HCl). From apocinchonidine and fuming  $HCl$  at 150° (Zorn, *J. pr.* [2] 8, 283; Hesse, *A.* 205, 346). Plates (from alcohol). Levorotatory.— $BH_2Cl_2$ — $B^*H_2PtCl_2$  2aq.

**Acetyl derivative**  $C_{19}H_{21}AcClN_2O$ . [150°]. Prisms (from ether). Levorotatory.— $B^*H_2PtCl_2$  2aq.

**(8)-Cinchonidine**  $C_{19}H_{21}N_2O$ . [207°]. [ $\alpha$ ]<sub>D</sub> = -181° in a  $\frac{1}{2}$  p.c. solution in dilute  $HCl$  at 15°. Formed, together with apocinchonidine, by heating cinchonidine with  $HCl$  (S.G. 1.105) at 140°. Separated from apocinchonidine through the insolubility of its tartrate (Hesse, *A.* 205, 327). Short prisms or plates. Levorotatory. The neutral tartrate is v. sl. sol. water. By heating with  $HCl$  for a long time it changes to apocinchonidine.— $BH_2PtCl_2$  aq.

**Iso-cinchonidine**  $C_{19}H_{21}N_2O$ . [235°]. Formed by dissolving cinchonidine in conc.  $H_2SO_4$  (Hesse, *A.* 248, 149). Colourless plates. V. sl. sol. ether, v. sl. alcohol and chloroform.

**CINCHONINE**  $C_{19}H_{21}N_2O$ . [236°] (when slowly heated); [248°–252°] (when quickly heated) (Hesse); [260°] (Skraup). [ $\alpha$ ]<sub>D</sub> = 226° in a 1 p.c. alcoholic solution; = 255° in dilute

$H_2SO_4$ ; = 268° in a 10 p.c. solution containing 1 mol.  $H_2SO_4$  at 15° (Hesse; cf. Oudemans, *Ar. Neerl.* 10, 193). S. 202 at 10°; S. (alcohol of S.G. .852) .71 at 10°; S. (ether) .27 at 10°; S. ( $CHCl_3$ ) .28. Occurs, together with quinine, in most of the true cinchona barks (Fourcroy, *Ann. Chim.* 8, 113; 9, 7; Vauquelin, *Ann. Chim.* 59, 30, 148; Gomez, *Edinb. Med. and Surg. Journal*, 1811, 420; Pfaff, *Schw. J.* 10, 365; Pelletier a. Caventou, *A. Ch.* 16, 291, 537; Pelletier a. Dumas, *A. Ch.* 24, 169; Gerhardt, *Revue scient.* 10, 886; Traité, 4, 105; Laurent, *A. Ch.* [3] 19, 363; Regnault, *A. Ch.* 68, 113; *A.* 26, 15; Liebig, *A.* 26, 49; Hlasiwetz, *A.* 77, 49; Weidel, *A.* 173, 76; Hesse, *A.* 122, 226; 135, 326; 166, 217; 205, 211; Skraup, *A.* 197, 353; Oudemans *A.* 182, 44).

**Preparation**.—The bark is extracted with dilute acid. The alkaloids are ppd. by lime,  $Na_2CO_3$ , or  $NaOH$ , and crystallised from alcohol (85 p.c.). Cinchonine crystallises out before quinine, unless the quantity of the latter present be relatively large, in which case a portion of the quinine is first removed by crystallisation of the sulphates. Quinine may be separated from cinchonine by ether, which dissolves quinine most readily.

**Properties**.—Prisms (from alcohol). When ppd. by ammonia from aqueous solutions of its salts it is amorphous, but rapidly becomes crystalline. Tastes bitter. Its solutions are alkaline to litmus and dextro-rotatory. Its solution in dilute  $H_2SO_4$  does not fluoresce. It does not give a green colour with chlorine-water and ammonia. It gives a yellow pp. with chloride of iodine.

**Reactions**.—1. Oxidised by  $KMnO_4$  to pyridine tri-carboxylic acid (Dobbie a. Ramsay, *C. J.* 35, 189). 10 g. cinchonine dissolved in 4.5 g.  $H_2SO_4$ , diluted with water to 100 c.c., and treated gradually with 285 c.c. of a 5 p.c. solution of  $KMnO_4$ , gives cinchotinic, cinchotene, and quinoline carboxylic acid (Skraup, *A.* 201, 294). In the syrupy oxidation products of cinchonine are a monobasic acid  $C_{19}H_{21}NO_4$ , a base  $C_{19}H_{21}NO_3$ , yielding an ethyl-pyridine identical with that of Wysznegradsky,  $C_{19}H_{21}NO_2$ , identical with Schmidberg a. Kretschy's base kynurine, and an amorphous product  $C_{19}H_{21}NO_2$  (Skraup, *M.* 7, 517, 518). Alkaline  $KMnO_4$  gives off 41 p.c. of the nitrogen as  $NH_3$  (Hoogewerff a. Van Dorp, *A.* 204, 90).—2.  $H_2SO_4$  and  $PbO_2$  give a red substance, cinchonetin (Marchand, *J. Chim. Med.* 10, 362).—3. Boiling  $HNO_3$  (S.G. 1.4) forms quinoline carboxylic (cinchoninic) acid, quinolic acid  $C_{19}H_{21}NO_6$ , pyridine dicarboxylic (cinchomeronic) acid, pyridine tri-carboxylic acid and a base  $C_{19}H_{21}N_2O_4$  (Weidel, *A.* 173, 76).—4.  $CrO_3$  gives quinoline carboxylic acid and some formic acid, which perhaps indicates a methoxyl group (Skraup, *A.* 201, 294).—5.  $PCl_5$  converts it into cinchonine-chloride  $C_{19}H_{21}N_2Cl$  [52°], which by boiling with alcoholic KOH gives cinchene  $C_{19}H_{21}N_2$ , and this by heating with  $HCl$  at 220°–230° is converted into apocinchene  $C_{19}H_{21}NO$  by splitting off  $MeCl$  and  $NH_3$  and taking up  $H_2O$  (Comstock a. Königs, *B.* 17, 1984).—6. Treatment with  $CuO$  and  $KOH$  gives quinoline and a resin whence oxidation produces pyridine dicarboxylic acid (Wysznegradsky, *B.* 13, 2318). 7. Distillation with solid potash yields methyl-

amine, (a) and (b) di-methyl-pyridine, (a) and (b) tri-methyl-pyridine, quinoline, and quinoline tetrahydride (Oechsner de Coninck, *A. Ch.* [5] 27, 458; *C. R.* 94, 87).—8. Aqueous KOH gives quinoline and a solid body (Butlerow, *J. R.* 10, 244); in presence of superheated steam KOH forms also methyl-quinoline (Krakau, *Bl.* [2] 45, 248).—9.  $H_2SO_4$  and a little water at  $150^\circ$  forms the isomeric cinchonidine; this body is also formed by fusing the acid sulphate of cinchonine. According to Jungfleisch a. Léger (*C. R.* 105, 1255) pure sulphate of cinchonide dissolved in a mixture of equal parts of water and pure  $H_2SO_4$  yields a colourless liquid, which when heated for some time to  $120^\circ$  and then rendered alkaline yields a pp. of six bases: cinchonidine ( $\alpha_D = +175.8^\circ$  in a  $\frac{2}{3}$  p.c. alcoholic solution), cinchonidine ( $\alpha_D = +195^\circ$ ), cinchonine ( $\alpha_D = -60^\circ$ ), cinchoniline ( $\alpha_D = +63^\circ$ ), all having the formula  $C_{20}H_{21}N_3O_2$ , and the two oxy-cinchonines ( $\alpha_D = +182.56^\circ$  and  $\alpha_D = -187.14^\circ$ ) of the formula  $C_{20}H_{21}N_3O_4$ . Fuming  $H_2SO_4$  forms cinchonine sulphonic acid.—10. HCl at  $150^\circ$  forms successively apocinchonine, diapocinchonine, and finally apocinchonine chlorohydrate.—11. The product of the action of sodium ethylate on cinchonine, after distilling with steam, yields  $C_{20}H_{21}N_3$ , a heavy reddish yellow viscous oil smelling like quinoline. The constitution of this base is probably  $C_{10}H_{11}N_2(C_2H_5)$  (Michael, *Am.* 7, 182).—12. Conc. HBrAq forms apocinchonine bromohydrate  $C_{20}H_{21}BrN_3O$  and the hydrobromide of that body  $C_{20}H_{21}BrN_3OH.Br_2$  (Skraup, *A.* 201, 324).

**Salts.**—B'HCl2aq. S. 4.2 at  $10^\circ$ ; S. (alcohol) 77 at  $16^\circ$ ; S. (ether) 35.  $[\alpha]_D = -163^\circ$  in a 1 p.c. aqueous solution;  $+212^\circ$  in presence of 2 mol. HCl (Hesse; cf. Schwabe, *J. Ph.* [3] 38, 589).—B'HCla. —B'HCl. —B'HI. —B'HI2aq (Elderhorst, *A.* 74, 80).—B'HI2Cl2: formed by mixing alcoholic solutions of cinchonine hydrochloride and of  $HgCl_2$  (Hinterberger, *A.* 77, 201). Needles. —B'H2ZnCl2aq. —B'H2ZnCl23aq. —B'H2ZnCl2aq. —B'H2SnCl2aq. —B'H2PtCl2aq. —amorphous pp. —B'HPtCl2aq. —B'HPtCl22aq. —B'HAuCl2. —B'HClO3: bulky crystalline tufts (Serullas, *A. Ch.* [2] 45, 278). —B'(HClO4)2aq (Bödecker, *A.* 71, 59; Dauber, *A.* 71, 66). —B'HBrc. —B'HIaq. —B'HI2aq. —B'HI2 (Bauer, *Ar. Ph.* [3] 5, 289; cf. Pelletier, *A. Ch.* [2] 63, 181). —B'HI2aq [92°]; trimetric brown tables (from alcohol) (Jörgensen, *J. pr.* [2] 3, 145; 15, 82). —B'HI2Cl2 [97°]. —B'HI2HgI2 (Caillot, *B. J.* 10, 193). —B'(H2SO4)2.H2I22aq. [140°–145°] (Jörgensen, *J. pr.* [2] 14, 356; cf. Herapath, *C. J.* 9, 151). —B'(H2SO4)2.H2I2. —B'H2SO4.H2I2. —B'H2SeO4.H2I2. —B'(H2C2O4)2.H2I2. —B'HIO3. Explodes at  $120^\circ$ . —B'HI2FeCy2aq: formed by mixing alcoholic solutions of cinchonine and  $H_2FeCy_2$ ; lemon-yellow pp.; v. sl. sol. alcohol (Dollfus, *A.* 65, 224). —B'HI2FeCy2aq: orange pp., formed by adding aqueous  $K_2FeCy_2$  to aqueous cinchonine hydrochloride—B'HSCy. —B'HNO3aq: prisms, v. sol. water.  $[\alpha]_D = -172^\circ$  (Bouchardat). —B'H2SO42aq. Hard prisms. S. 1.5 at  $13^\circ$ .  $[\alpha]_D = -169^\circ$  in a 1 p.c. aqueous solution;  $+193^\circ$  in a 1 p.c. alcoholic solution (Hesse).  $[\alpha]_D + [\alpha]_L = 1.268$  (Grimbert, *J. Ph.* [5] 16, 295). —B'HSO3aq: trimetric octahedra (Baup, *A. Ch.* [2] 27, 323). —B'HSO3aq. —B'HSO32aq. —B'H2S2O4aq. —B'H2CrO4. —B'H2PO412aq. —

B'H2AsO412aq. —Oxalate B'H2C2O42aq. S. 1 at  $10^\circ$ . —Succinate B'C2H3O412aq. —B'C2H3O4aq. —Tartrate B'C2H3O42aq. S. 3 at  $16^\circ$ . —Acid tartrate B'C2H3O44aq. S. 1 at  $16^\circ$  (Pasteur, *J.* 1853, 419). —Lactotartrate B'C2H3O4aq. S. (alcohol) 3 at  $19^\circ$ ; v. sl. sol. water. —Citrate B'C2H3O44aq. S. 2.1 at  $12^\circ$ . —Acid citrate B'C2H3O44aq. S. 1.8 at  $15^\circ$ . —Urate B'C2H3O44aq. —Picrate B'(C2H3(NO2)2(OH))2. —Benzoate B'HO2C. S. 6 at  $15^\circ$ .

**Acetyl derivative**  $C_{20}H_{21}AcN_3O$ .  $[\alpha]_D = -114^\circ$  in a 2 p.c. alcoholic solution. Amorphous; v. sol. alcohol and ether. —B'HPtCl2aq. B'(HAuCl2)aq.

**Benzoyl derivative**  $C_{20}H_{21}BzN_3O$ . Amorphous (Schützenberger, *A.* 108, 351). —B'HPtCl2aq.

**Methyl-cinchonine**  $C_{19}H_{21}MeN_3O$ . [74°]. From cinchonine by successive treatment with MeBr and aqueous KOH (Claus, *B.* 13, 2286; cf. Stahlschmidt, *A.* 90, 218). Tables (from ether). B'HBraq. *Cinchonine methyl-bromide*. [248°]. From cinchonine and MeBr. Said not to be identical with the compound of methyl-cinchonine with HBr. —B'HI [254°]. —B'HI [162°]. —B'HPtCl2aq. —B'HBMeBr [235°]. From cinchonine (1 mol.) and MeBr (2 mols.) at  $150^\circ$ . B'Mel. [201°]; needles. —B'MeLi. [235°].

**Ethyl-cinchonine**  $C_{22}H_{23}N_3O$ . [50°]. Crystalline solid. Prepared by the action of alcoholic KOH on cinchonine-ethyl-iodide (Claus a. Kemperdick, *B.* 13, 2286; cf. Howard, *C. J.* 26, 1183).

**Salts.**—B'HI. [260°]. *Cinchonine ethyl-iodide*. White needles. From cinchonine and EtI. —B'HClaq. —B'HBrc. —B'HI [142°] (Jörgensen, *J. pr.* [2] 3, 152). —B'HI2PtCl22aq: yellow pp. The gold double chloride forms small yellow plates.

**Ethyl-iodide** B'EtI. [242°]. From ethyl-cinchonine and EtI. Fine white needles. With KOH it gives di-ethyl-cinchonine, B'HEtI2. *Cinchonine di-ethyl-iodide*: B'EtI2aq. [264°]. Yellow prisms sol. water.

**Benzyl-cinchonine**  $C_{20}H_{21}N_3O$ . [117°]. Colourless needles. Prepared by the action of KOH on cinchonine-benzyl-chloride (Claus a. Treupel, *B.* 13, 2294). —B'HI2Cl. *Cinchonine benzyl-chloride*. [248°]. From cinchonine and  $C_6H_5Cl$  in alcohol. Needles, sol. hot water and alcohol. Ag2O converts it into  $C_{20}H_{21}(C_6H_5)N_3O$  said not to be identical with the isomer got by the action of KOH (Claus). —Carbonate [115°]. —B'HI2PtCl22aq: yellow crystalline pp.

**Benzyl-chloride** B'CH2Cl. [255°]; colourless needles.

**Di-chloro-cinchonine**  $C_{19}H_{19}Cl_2N_3O$ . The hydrochloride is ppd. by passing chlorine into a conc. solution of cinchonine hydrochloride (Laurent, *A. Ch.* [3] 24, 302). Crystalline. —B'HCla. S. (alcohol) 2. —B'HPtCl2aq. —B'HBrc.

**Bromo-cinchonine**  $C_{19}H_{21}BrN_3O$ . Formed by adding Br to an alcoholic solution of cinchonine (Laurent, *A. Ch.* [3] 24, 302; A. Kopp, *Ar. Ph.* [3] 9, 34). Boiling alcoholic KOH gives 'oxycinchonine' [205°]. —B'HCla.

**Di-bromo-cinchonine**  $C_{19}H_{19}Br_2N_3O$ . Formed by bromination of cinchonine (Comstock a. Königs, *B.* 17, 1995; cf. Laurent, *Compt. chim.*

1849, 311). Colourless crystals containing aq. Sl. sol. alcohol, insol. water. Alcoholic KOH is said by H. Strecker (A. 123, 380) to convert it into an oxycinchonine which crystallises from alcohol in plates.

**Cinchonine - (a) - di - bromide**  $C_{19}H_{22}N_2Br_2O$ . Formed by the action of bromine upon cinchonine dissolved in a mixture of chloroform and spirit. Crystallises with aq. Boiled with alcoholic KOH it is converted into dehydrocinchonine  $C_{19}H_{20}N_2O$ . —  $C_{19}H_{22}N_2Br_2O \cdot H_2Br_2$  (Comstock a. Königs, B. 19, 2851; 20, 2510).

**Cinchonine - (β) - di - bromide**  $C_{19}H_{22}N_2Br_2O$ . Formed at the same time as the preceding, from which it differs in crystallising in an anhydrous condition.

**Cinchonine - di - bromide - sulphuric acid.** Formed by several hours' standing at the ordinary temperature of a solution of cinchonine-di-bromide in 7-8 parts of conc.  $H_2SO_4$ . Crystalline solid. Sl. sol. cold water, v. sol. aqueous alkalis, an excess of which precipitates the alkaline salts of the acid. By heating with dilute HBr at c.  $130^\circ$  it is split up again into cinchonine-di-bromide and  $H_2SO_4$  (Comstock a. Königs, B. 19, 2855).

**Cinchonine-chloro-hydrate**  $C_{19}H_{22}ClN_2O$ . *Hydrochlorcinchonine*. [213°]. Formed by allowing a solution of cinchonine in fuming HCl (saturated at  $-17^\circ$ ) to stand at the ordinary temperature for several weeks. Colourless crystals (from alcohol). By boiling with alcoholic KOH it yields isocinchonine and a little cinchonine. The hydrochloride  $C_{19}H_{22}ClN_2O \cdot H_2Cl$  crystallises in prisms (Comstock a. Königs, B. 20, 2519).

**Cinchonine-bromo-hydrate**  $C_{19}H_{22}BrN_2O$ . *Hydrobromcinchonine*. 'Bromcinchonide' of Skraup. Formed by the action of fuming HBr (saturated at  $-17^\circ$ ) upon cinchonine at the ordinary temperature or at  $100^\circ$ . Boiled with alcoholic KOH it gives a mixture of cinchonine and isocinchonine. —  $C_{19}H_{22}BrN_2O \cdot H_2Br_2$  (Comstock a. Königs, B. 20, 2520).

**Cinchonine - chloride**  $C_{19}H_{21}N_2Cl$ . [72°]. Formed by heating the hydrochloride of cinchonine with  $POCl_3$  and  $PCl_5$ . Trimetric prisms. By boiling with alcoholic KOH it yields cinchene  $C_{19}H_{20}N_2$  (Comstock a. Königs, B. 14, 1854; 17, 1984).

**Dehydro - cinchonine**  $C_{19}H_{20}N_2O$ . [203°]. Formed by heating cinchonine-di-bromide with alcoholic KOH. Colourless needles. Sublimable. V. sol. alcohol, acetone, and chloroform, m. sol. ether and hot benzene, v. sl. sol. ligroin and water. — B'HBr: colourless prisms. — \* B'HC1: very soluble long silky needles (Comstock a. Königs, B. 19, 2856).

**Dehydro-cinchonine-bromo-hydrate**  $C_{19}H_{21}BrN_2O$ . *Hydrobromdehydrocinchonine*. *Bromo-cinchonine*. [c. 285°]. \* Crystalline. Formed by allowing a solution of dehydrocinchonine in very conc. HBr to stand for 8 days at the ordinary temperature (Comstock a. Königs, B. 20, 2524).

**'Dehydrocinchonine - chloride'**  $C_{19}H_{19}N_2Cl$ . [149°]. Formed by the action of  $PCl_5$  upon dehydrocinchonine. Colourless crystals. V. sol. alcohol, ether, acetone, chloroform, and benzene, nearly insol. ligroin. By boiling with alcoholic

KOH it is converted into dehydrocinchene  $C_{19}H_{18}N_2$  (Comstock a. Königs, B. 19, 2857).

**Di-hydro-di-cinchonine**  $(C_{19}H_{22}N_2O)_2$ . [258°]. Formed by treating an acid solution of cinchonine with sodium-amalgam or with zinc and  $H_2SO_4$  (Zorn, J. pr. [2] 8, 293; Howard, C. J. 26, 1179; Skraup, B. 11, 312). Scales (from alcohol). — B'II $_2SO_4$ .

**Hydrocinchonine**  $C_{19}H_{21}N_2O$ . Formed at the same time as the above. Amorphous. When Cl is passed into an aqueous solution of its chloride there is formed hexa-chloro-hydrocinchonine  $C_{19}H_{15}Cl_6N_2O$  and tetra-chloro-dispoline  $C_{11}H_7Cl_4N$ .  $HNO_3$  converts hydrocinchonine into amorphous tetra-nitro-hydrocinchonine  $C_{19}H_{15}(NO_2)_4N_2O$ .

**Cinchonibine**  $C_{19}H_{21}N_2O$ . [259°].  $[\alpha]_D = 176^\circ$  (in alcohol);  $= 220^\circ$  (in HCl aq.). Insol. water and ether. Alkaline to litmus, but not to phenol-phthalein. — B'MeI. — B'Me $_2$ I. 1 aq. — B'EtI. — B'Et $_2$ I. (Jungfleisch a. Léger, C. R. 106, 1410).

**Cinchonigine**  $C_{19}H_{21}N_2O$ . [288°].  $[\alpha]_D = -60^\circ$ . The bases formed from cinchonine by heating with sulphuric acid can be separated by ether. From the ethereal extract HCl pps. cinchonigine hydrochloride and the mother-liquor on concentration, addition of soda and re-extraction with ether gives with HI cinchoniline hydro-iodide. The bases insoluble in ether are 4 in number, and are separated by weak alcohol, in which cinchonibine and cinchonigine are insoluble, while (a) and (β) oxycinchonine dissolve (Jungfleisch a. Léger, C. R. 106, 68, 357).

**Properties.**—Colourless prisms, volatile, distils under reduced pressure, sol. alcohol and dilute HCl. Sl. sol. water; v. sol. chloroform, benzene, and acetone; less sol. dry ether. Probably identical with the base obtained by Caventou a. Girard (C. R. 106, 71) by heating cinchonine with oxalic acid and  $H_2SO_4$ .

**Salts.**—B'HC1 aq.; [213°]. — B' $^2$ HCl aq. — B'HB aq. — B'III aq. — B' $^2$ III aq. — B' $^2$ C $_6$ H $_5$ O $_2$ ; needles. — B'C $_6$ H $_5$ O $_2$  3 aq. — B'MeI [253°]; colourless needles. — B'EtI aq [232°]; large prisms from alcohol. — B'EtBr aq. — B'II $_2$ PCl $_4$  aq (Jungfleisch a. Léger, C. R. 106, 357).

**Cinchoniline**  $C_{19}H_{20}N_2O$ . [130°].  $[\alpha]_D = +53.2^\circ$  in alcohol. Prepared as above. Rhombic prisms, dextro-rotatory. Sl. sol. water, v. sol. most solvents. Its aqueous solution is turned blue by litmus and red by phenol-phthalein. Reduced in the cold by  $KMnO_4$ . Yields the same products as cinchonine on heating.

**Salts.**—B'HC1 3 aq [226°]; v. sol. water  $[\alpha]_D = +5^\circ$ . — B' $^2$ HClPCl $_4$  aq; yellow prisms. — B' $^2$ HClAuCl $_3$  3 aq; prisms. — B'HB 3 aq; prisms, less soluble than the chloride. — B'HI aq; B' $^2$ III; B'HCNS aq.

**Methyl and ethyl compounds** B'MeI [235°]; B'EtI; B'EtBr are all three v. sol. most solvents (Jungfleisch a. Léger, C. R. 106, 657).

**Cinchotenine**  $C_{19}H_{20}N_2O$ . [198°].  $[\alpha]_D = 135^\circ$  in a 2 p.c. alcoholic solution. The chief product of the action of  $KMnO_4$  on cinchonine dissolved in dilute  $H_2SO_4$  (Skraup, B. 11, 311; A. 197, 376). Needles or plates (containing 3 aq). Dextro-rotatory. Not attacked by cold  $KMnO_4$ . — B' $^2$ H $_2$ PCl $_4$ ; prisms. — B'(HAcCl) $_2$ ; needles.

**Cinchotenine**  $C_{19}H_{20}N_2O$ . [153°]. The sulphate is formed by fusing cinchotenine sulphate

It is feebly dextrorotatory, and forms an amorphous platinumchloride.

Cinchoninicine  $C_{10}H_{22}N_2O$ .  $[\alpha]_D = 46.5^\circ$  in a 2 p.c. solution in chloroform. Formed by heating the acid sulphate of cinchonine or cinchonidine (Pasteur, *C. R.* 37, 110; Hesse, *A.* 178, 253). Formed also by heating the tartrate or acid tartrate of cinchonine, and by heating cinchonine, cinchonidine, or cinchonine sulphate with glycerin (Howard, *C. J.* 25, 102; Hesse, *A.* 147, 242; 166, 277). Slightly yellowish viscid mass, which becomes a mobile liquid at  $50^\circ$ .  $\bullet$  V. sol. alcohol and ether. Its alcoholic solution tastes bitter and is alkaline to litmus. Cl and  $NH_3$  give no green colour. Bleaching powder gives a white pp. in a solution of its hydrochloride (difference from cinchonine and cinchonidine). Dextrorotatory.

Salts.—B'HI: prisms, m. sol. cold water.— $B'H_2Cl_2(PtCl_2)_2$  aq (?).— $B'HI.PtCl_2$  aq.—Oxalate  $B'H_2C_2O_4$  aq: slender prisms.—Acid tartrate  $B'C_4H_4O_6$  aq.

Apocinchonine  $C_{10}H_{22}N_2O$ . [209°].  $[\alpha]_D = 160^\circ$  in a 1 p.c. alcoholic solution at  $16^\circ$  (Hesse, *A.* 205, 330; Oudemans, *R. T. C.* 1, 173). Formed, together with diapocinchonine, by heating cinchonine with HCl (S.G. 1.125) at  $150^\circ$ . The product is nearly neutralised with ammonia, alcohol is added, and the solution heated to boiling; excess of  $NH_3$  now pps. apocinchonine. Prisms, sl. sol. ether, insol. water.

Salts.—The salts are dextrorotatory, for the neutral salt  $[\alpha]_D$  varies from  $180^\circ$  to  $215^\circ$ ; for the basic salts from  $161^\circ$  to  $176^\circ$ .— $B'HI.Cl_2$  aq.— $B'HI.PtCl_2$  2aq. —  $B'HI.Br$  aq. —  $B'HI$  aq. —  $B'H_2SO_4$  2aq (H.).— $B'HI.SO_3$  3aq (O.).— $B'HI.ClO_3$ .  $B'HI.ClO_4$  aq. —  $B'H_2C_2O_4$  2aq.

Acetyl derivative  $C_{10}H_{21}AcN_2O$ .  $[\alpha]_D = 71^\circ$  in a 2 p.c. alcoholic solution at  $15^\circ$ .— $B'HI.PtCl_2$  2aq.

Apocinchonine chlorohydrate  $C_{10}H_{21}ClN_2O$ . [197°].  $[\alpha]_D = 211^\circ$  (Oudemans).— $205^\circ$  (Hesse) in  $\frac{1}{2}$  p.c. alcoholic solution at  $16^\circ$ . Formed by heating cinchonine or apocinchonine with saturated HCl aq at  $150^\circ$  (Zorn, *J. pr.* [2] 8, 280; Hesse, *A.* 205, 348). Needles; v. sl. sol. water; sl. sol. ether and alcohol. Dextrorotatory. In the case of the neutral salts  $[\alpha]_D$  varies from  $215^\circ$  to  $229^\circ$ ; for the basic salts it lies between  $192.5^\circ$  and  $195^\circ$  (O.).— $B'HI.Cl_2$ .— $B'HI.Cl$  aq.— $B'HI.Br$ .— $B'HI.PtCl_2$  2aq. —  $B'H_2SO_4$  3aq. —  $B'HI.NO_3$ .— $B'HI.ClO_3$ .— $B'HI.ClO_4$  aq.— $B'H_2C_2O_4$  aq.

Acetyl derivative  $C_{10}H_{21}AcClN_2O$ .  $[\alpha]_D = 108^\circ$  in a 2 p.c. alcoholic solution at  $15^\circ$ . Amorphous; v. sol. alcohol and ether.

Apocinchonine bromohydrate  $C_{10}H_{21}BrN_2O$ . From cinchonine and conc. HBr aq at  $100^\circ$  (Skraup, *A.* 201, 324). Scales (from alcohol).— $B'H_2Br_2$ : crystals.

Apocinchoninicine  $C_{10}H_{22}N_2O$ . A resinous base, formed by heating apocinchonine acid sulphate at  $140^\circ$ . Inactive; v. sol. alcohol and ether.— $B'HI.PtCl_2$  2aq.

Di-apocinchonine  $(C_{10}H_{22}N_2O)_2$ .  $[\alpha]_D = 20^\circ$  in a 2 p.c. alcoholic solution at  $15^\circ$ . Formed by the prolonged action of HCl on apocinchonine. Amorphous powder, v. sol. alcohol and ether. Dextrorotatory.— $B'HI.PtCl_2$  4aq: amorphous.

Acetyl derivative  $C_{20}H_{41}Ac_2N_4O_2$ .  $[\alpha]_D = 26^\circ$  in a 2 p.c. alcoholic solution. Yellow

amorphous mass.— $B'HI.PtCl_2$  4aq; amorphous pp.— $B'(HAuCl_4)_2$  2aq.

Iso-cinchonine  $C_{10}H_{22}N_2O$ . [127°].

Crystalline. Formed together with cinchonine by boiling cinchonine-chloro- or bromo-hydrate ( $C_{10}H_{21}ClN_2O$  or  $C_{10}H_{21}BrN_2O$ ) with alcoholic KOH.  $\bullet$  V. e. sol. alcohol, ether, benzene, chloroform, acetic ether, and  $CS_2$ , sl. sol. ligroin, nearly insol. water. It forms easily soluble salts. The zinc double chloride  $C_{10}H_{21}N_2O$ ,  $ZnCl_2$ ,  $H_2Cl_2$  forms small needles (Counstock & Königs, *B.* 20, 2521). A substance called isocinchonine has also been obtained by Hesse (*A.* 243, 149) among the products of the action of conc.  $H_2SO_4$  on cinchonine.

CINCHOTENICINE v. CINCHONINE.

CINCHOTENIDINE v. CINCHONINE.

CINCHOTENINE v. CINCHONINE.

CINCHOTINE v. CINCHONA BASES.

CINCHOVATINE v. ARICINE.

CINENE  $C_{10}H_{16}$ . *Cymene*. ( $181^\circ$ – $182^\circ$ ). S.G. 1.854 (Wallach & Brass, *A.* 225, 309).

Formation.—1. By passing HCl into boiling oleum cine (worm-seed oil) or cineol (cf. Volckel, *A.* 89, 358).—2. From cineol and  $BzCl$ .—3. From  $C_{10}H_{14}I_2$  (got from cineol and HI) and aniline.—4. Among the products of the distillation of caoutchouc (when it is called caoutchin).—5. By heating isoprene at  $260^\circ$ .

Properties.—Oil, with pleasant odour of lemon.

Reactions.—1. Bromine added to its cold solution in alcohol or ether forms the tetrabromide  $C_{10}H_{12}Br_4$  [ $125^\circ$ ].—2. Conc.  $H_2SO_4$  converts it into cymene, giving off  $SO_2$ .  $PS_5$  behaves similarly. (V. also TERPENES.)

Dihydrochloride  $C_{10}H_{16}Cl_2$ . [ $50^\circ$ ].

Dihydrobromide  $C_{10}H_{16}Br_2$ . [ $64^\circ$ ]. White silky plates. Formed by the action of HBr gas upon worm-seed oil. It is slowly decomposed on standing in contact with alcohol. On heating or by boiling with water or dilute alkalis it loses HBr giving cineene. It decomposes on keeping in the course of several weeks (Hell & Ritter, *B.* 17, 2609).

Dihydroiodide  $C_{10}H_{16}I_2$ . [ $77^\circ$ ]. White felted needles. Formed by the action of gaseous HI upon worm-seed oil. It decomposes on keeping in the course of a few days, and quickly in contact with alcohol. By zinc-dust and water it is reduced to cineene-dihydrate  $C_{10}H_{18}$  (Hell & Ritter, *B.* 17, 2611).

Dihydrate  $C_{10}H_{18}$ . ( $166^\circ$ ). V.D. = 5 (obs.). Colourless liquid, of ethereal odour. Formed by boiling cineene-dihydrochloride or cineene-dihydroiodide with zinc-dust and water (Hell & Ritter, *B.* 17, 2612).

CINEOL  $C_{10}H_{18}O$ . ( $176^\circ$ ). S.G. 22.927.  $\mu_D = 1.458$ . V.D. 5.12 (Wallach & Brass, *A.* 225, 295; 245, 195; Gladstone, *C. J.* 49, 621). The chief constituent of oleum cine and of oil of cajuput; occurs also in oil of rosemary (Weber, 238, 89). Liquid smelling like camphor, inactive. Boiling  $HNO_3$  (S.G. 1.15) forms oxalic acid only.

Reactions.—1. HCl passed into its solution in ligroin forms crystals of  $(C_{10}H_{17}O)_2HCl$ , a body which is decomposed by water, reproducing cineol, but when heated alone produces cineene:  $(C_{10}H_{17}O)_2HCl = 2H_2O + HCl + C_{10}H_{16}$ .—2. HI passed into oleum cine ultimately converts it into a crystalline mass of  $C_{10}H_{17}I$ . Crystallised

from light petroleum, this forms trimetric tablets:  $\alpha:b:c = .7588:k:7074$  [78.5°]. Alcoholic KOH converts it into cineene.—3. Excess of Bromine added at 0° to a solution of cineol in light petroleum forms red crystals of  $C_{10}H_{16}OBr_2$ . These crystals decompose on keeping, forming cineine tetrabromide and water:  $2C_{10}H_{16}OBr_2 = C_{10}H_{12}Br_4 + 2H_2O + C_{10}H_{16}$ . When a smaller quantity of Br is added to a solution of cineol in light petroleum, needles of  $(C_{10}H_{16}O)_2Br_2$  are formed (Wallach, A. 230, 228).—4. Cineol also combines with iodine forming crystals of  $(C_{10}H_{16}O)_2I_2$ .

**Constitution.**—Sodium, PCl, in the cold, and BzCl at 120° do not act on cineol. Hence it appears not to contain hydroxyl. At 150° BzCl removes  $H_2O$ . Hydroxylamine and phenylhydrazine do not act on cineol. Brühl (B. 21, 461) gives cineol the constitution

since it is optically inactive and on

passing HCl through it it is converted into opti-

cally inactive

**Isomerides of Cineol** are described under BORNEOL; v. also CAMPHORS, vol. i. p. 672. The matter will be less complicated if we can assume the existence of only two compounds of the formula  $C_{10}H_{16}O$ , with rotatory power +38° and -38° respectively, the others being mixtures of these in varying proportions. Thus the levorotatory camphols ( $[\alpha]_D = -38^\circ$ ) derived from *Bluncea balsamifera* (Ngai camphor and also, from the same tree, Bang Phien), Martico camphor, the camphor from oil of valerian, and that from madder, are in all respects identical (Haller, C. R. 103, 64, 151). Ordinary borneol is a cineol of rotatory power +38°. Camphol from amber appears to be partly of the racemic character (i.e. an inactive compound of camphols of rotatory power +38° and -38°) and partly of dextrorotatory borneol (Haller, C. R. 104, 66). By dissolving a camphol (50 g.) in toluene (150 g.), heating with sodium (6 g.) and passing in cyanogen a product is got whence water extracts a camphyl carbamate  $C_{10}H_{15}.O.CO.NH_2$ . The product derived from dextrorotatory camphol is described (vol. i. p. 523) as bornyl carbamate. It is dextrorotatory and forms dextro-hemihedral crystals. Levorotatory camphol forms an isomeride [127°] which is levorotatory ( $[\alpha]_D = -29.90^\circ$ ), and crystallises in levo-hemihedral forms. In each preparation, camphyl carbonate  $(C_{10}H_{15})_2CO_3$  is a by-product; the carbonate from borneol is dextrorotatory while that from levorotatory camphol is levorotatory. Both melt at 215° (Haller, C. R. 98, 578).

**CINNAMENIN** v. *Benzyl ether of CINNAMIC ACID.*

**CINNAMENE** v. **STYRENE.**

**CINNAMENYL COMPOUNDS**

$C_6H_5.CH:CH-X$  v. **STYRYL COMPOUNDS.**

**CINNAMENYL-AMIDO-PHENYL-MER-CAPTAN**  $C_{11}H_{11}NS$  i.e.

$C_6H_5.N \begin{smallmatrix} \diagup \\ \diagdown \end{smallmatrix} C_6H_4.CH:CH.C_6H_5$  [111°]. Prepared by the action of cinnamic acid on amido-phenyl-mercaptan (Hofmann, B. 13, 1235). Colourless prisms. Sol. alcohol. Weak base. On fusion with KOH it is split up into cinnamic acid (which is further converted into benzoic acid) and amido-phenyl-mercaptan.

**Salts.**—B'HCl: unstable salt.—

(B'HCl)PtCl<sub>2</sub>: yellow needles.

**CINNAMIC ACID**  $C_9H_8O_2$  i.e.

$C_6H_5.CH:CH.CO_2H$ . *Phenyl-acrylic acid. Benzylidene acetic acid.* Mol. w. 148. [133°] (Kraut, A. 133, 93; 147, 112). (300°). S.G.  $\frac{1}{4}$  1.248 (Schröder, B. 12, 1612). S. 0.3 at 17°; S. (alcohol) 2.3 at 20°; S. (CHCl<sub>3</sub>) 6 at 15°; S. (CS<sub>2</sub>) .9 at 15°. *Electrical conductivity:* Ostwald, J. pr. [2] 32, 365.

**Occurrence.**—1. In oil of cinnamon (Duffas a. Péligot, A. Ch. 57, 311; Herzog, Ar. Ph. 17, 72; 20, 159).—2. In liquid storax which contains styrene, cinnamic acid, and styryl cinnamate (styracin) (E. Simon, A. 31, 265; D. Howard, C. J. 13, 135; Beilstein a. Kuhlberg, Z. [2] 7, 489).—3. In balsam of Peru, which contains benzyl cinnamate, benzoic acid, and cinnamic acid (E. Kopp, Compt. chim. 1847, 198; 1849, 146; 1850, 140; Kraut, B. 2, 180; Delafontaine, Z. 1869, 156).—4. In balsam of Tolu, which is similar in composition to that of Peru (Frémy, A. 30, 338; Deville, A. 44, 304; E. Kopp, A. 60, 269; Busse, B. 9, 830).—5. In gum benzoin from Sumatra (Kolbe a. Jantemann, A. 119, 186). 6. In the leaves and stalks of *Globularia vulgaris* (Heckel a. Schlagdenhauffen, A. Ch. [5] 28, 69). 7. In the leaves of *Eukalanthus japonicus* (Eykman, R. T. C. 5, 297).

**Formation.**—1. By heating benzoic aldehyde with AcCl for 24 hrs. at 125° (Bertagnini, Cimento, 4, 46; A. 100, 126).—2. By heating benzoic aldehyde with HOAc and ZnCl<sub>2</sub> at 160° (Schiff, B. 3, 412; Z. [2] 6, 700).—3. By heating benzoic aldehyde (2 pts.), Ac<sub>2</sub>O (3 pts.), and NaOAc (1 pt.) at 145° (Perkin, C. J. 31, 389; Slocum, A. 227, 58). This reaction, commonly known as Perkin's synthesis, is discussed under ALDEHYDES (vol. i. p. 108).—4. By the action of benzoic aldehyde on sodium malonate in presence of Ac<sub>2</sub>O in the cold, CO<sub>2</sub> being evolved:  $Ph.CHO + CH_2(CO_2H)_2 = Ph.CH:CH(CO_2H)_2 + H_2O = Ph.CH:CH.CO_2H + CO_2 + H_2O$  (Stuart, C. J. 43, 404).—5. By heating benzoic aldehyde with malonic acid at 130° (Michael, Am. 5, 205).—6. By the action of KOH on benzyl-chloro-malonic ether (Conrad, B. 13, 2160).

**Properties.**—Monoclinic prisms (from alcohol) (Schabus, Sitz. W. 1850, ii. 206). When quickly distilled it is but little decomposed, but when slowly distilled it splits up into CO<sub>2</sub> and styrene (Howard, C. J. 13, 135). Volatile with steam. V. sl. sol. water, v. sol. alcohol, v. e. sol. ether; v. sl. sol. cold ligroin.

**Reactions.**—1. Distillation with lime gives styrene and benzene.—2. Potash-fusion gives potassium acetate and benzoate (Chiozza, A. Ch. [3] 39, 439; Kraut, A. 147, 113). Fusion with NaOH gives CO<sub>2</sub> and benzene (50 p.c. of theoretical) (Barth a. Schröder, B. 12, 1257).—3. SO<sub>2</sub> forms sulphobenzoic acid. Boiling with H<sub>2</sub>SO<sub>4</sub>,

diluted with 1 to 1½ vols. water forms an oil, consisting of distyrene  $C_{10}H_{10}$ , and distyrenic acid  $C_{10}H_8O_2$ .—4. Conc.  $HNO_3$  gives nitro-benzoic acid, but a more dilute acid gives benzoic aldehyde.—5. Boiling with  $PbO_2$  in aqueous solution forms benzoic aldehyde and lead benzoate (Stenhouse, *A.* 55, 1; 57, 79).—6. *Chromic mixture* also forms benzoic aldehyde (Simon).  $KMnO_4$  in feebly alkaline solution acts in the same way (A. Bauer, *A.* 220, 37).  $KMnO_4$  in very dilute neutral solution at 0° oxidises cinnamic acid to  $PhCH(OH).CH(OH).CO_2H$  (Rittig, *B.* 21, 919).—7. Br gives di-bromo-phenyl-propionic acid (A. Schmitt, *A.* 127, 319).—8. Fuming  $HBr$  gives bromo-phenyl-propionic acid.  $HI$  acts in a similar way.—9. *Sodium amalgam* reduces it to phenyl-propionic acid (Erlenmeyer, *A.* 137, 327). Conc.  $HIAq$  does the same (Popoff, *Z.* [2] 1, 111). 10.  $HClO$  gives chloro-oxy-phenyl-propionic acid (Glaser, *A.* 147, 78; *Z.* [2] 3, 65; 4, 131).—11. Boiling aqueous  $K_2SO_5$  gives sulpho-phenyl-propionic acid.—12. Chlorine acts on aqueous sodium cinnamate in two ways, viz.:

producing  $\alpha$ -chloro-styrene and chloro-oxy-phenyl-propionic acid (Erlenmeyer, *A.* 219, 184).—13. *Diphenylamine* and  $ZnCl_2$  at 250° form phenyl-acridine (Bernthsen, *B.* 20, 1552).—14. *m-Oxy-benzoic acid* and  $H_2SO_4$  form a body  $C_{10}H_8O_3$ , or  $C_6H_5 < \begin{smallmatrix} // \\ C \\ // \end{smallmatrix} \begin{smallmatrix} CH.CO \\ CO \end{smallmatrix} > O$  [260°] (Kostanecki, *B.*

20, 3137). It forms a diacetyl derivative [260°]. 15. *s-Di-oxy-benzoic acid* and  $H_2SO_4$  give the oxy-derivative of the preceding [325°] which forms a crystalline acetyl derivative  $C_{10}H_8AcO_4$  [255°] (K.).—16. Gallic acid and  $H_2SO_4$  at 50° form, in the same way, 'styrogallol,' a dioxy-derivative of the above  $C_{10}H_8O_4$ , which crystallises in minute yellow needles, melting above 350° (Jacobsen a. Julius, *B.* 20, 2598). Its di-acetyl derivative melts at 260°.

**Salts** (Herzog, *J. pr.* 29, 51; E. Kopp, *C. R.* 53, 634).— $NH_4A'$   $\frac{1}{2}aq$ : sl. sol. cold water.— $KA'$   $\frac{1}{2}aq$ : monoclinic crystals; v. sol. water, m. sol. alcohol.— $NaA'$   $\frac{1}{2}aq$ : needles (from dilute  $NaOHaq$ ).— $NaHA'$  (Perkin, *C. J.* 31, 388).— $AgA'$ : curdy pp. insol. boiling water.— $BaA'$   $\frac{1}{2}aq$  (Herzog).— $BaA'$   $\frac{1}{2}aq$ : pearly plates (Kopp).— $BaA'$   $\frac{3}{4}aq$ : iridescent leaflets or striated prisms (Rebuffat, *G.* 11, 160).— $CaA'$   $\frac{1}{2}aq$  (H.; R.).— $CaA'$   $\frac{3}{4}aq$  (K.). *S.* 16 at 17°.— $SrA'$   $\frac{1}{2}aq$ : caecious needles.— $MgA'$   $\frac{3}{4}aq$ : white needles.— $CuA'$   $\frac{1}{2}(CuO_2)I_2$ : greenish-blue pp.— $PbA'$ : crystalline powder or flattened needles.— $CdA'$   $\frac{1}{2}aq$ .— $MnA'$   $\frac{1}{2}aq$ .— $ZnA'$   $\frac{1}{2}aq$ : prismatic needles (from hot water).

**Methyl ether**  $MeA'$ . [34°]. (263° i.V.). *S.G.*  $\frac{1}{2}$  1.0415. Formed by the action of the ethyl ether on methyl alcohol in presence of  $NaOMe$  (Purdie, *C. J.* 51, 628; cf. E. Kopp, *C. R.* 21, 1876; Anschütz a. Kinnicutt, *B.* 11, 1220; Weger, *A.* 221, 74). With Br it forms  $C_6H_5.CHBBr.CHBBr.CO_2Me$  [117°].

**Ethyl ether**  $EtA'$ . [12°] (Friedländer, *A.* 221, 75). (268°) at 741 mm. (Brühl, *A.* 235, 19). (271° i. V.) (A. a. K.). *S.G.*  $\frac{1}{2}$  1.0490.  $\mu_D$  1.560 (B.). **Preparation**.—Cinnamic acid (500 g.) is dissolved in dry alcohol (1 litre) and  $HCl$  is passed in to saturation. After 3 hrs. the product is poured into ice-cold water. The oil is washed, dissolved in ether, and shaken with aqueous sodic carbonate, dried over  $CaCl_2$ , and the ether evaporated (Perkin, jun., *C. J.* 45, 17; cf. Herzog, *Ar. Ph.* [2] 17, 72; Marchand, *A.* 32, 269; E. Kopp, *J. pr. Pharm.* [3] 11, 72; Plantamour, *A.* 30, 345). **Reactions**.—1. With bromine it forms  $C_6H_5.CHBBr.CHBBr.CO_2Et$  [69°].—2. *Sodium-aceto-acetic ether* in presence of alcohol at 100° forms an acid  $C_{10}H_8O_4$  [140°]. Its silver salt,  $AgA'$ , forms radiating prisms, insol. water (Michael, *J. pr.* [2] 35, 354).—3. With *sodium malonic ether* at 100° in presence of alcohol it forms an oil  $C_{10}H_8O_4$  (305°–310°) or (215° at 15 mm.).  $Ph.CH:CH.CO_2Et + NaHC(CO_2Et)_2$   
 $Ph.CH.CHNa.CO_2Et$   
 $= \begin{array}{c} \text{CO}_2Et \\ | \\ \text{CH} \\ | \\ \text{CO}_2Et \end{array} + H_2O$   
 $Ph.CH.CH_2.CO_2Et$   
 $= \begin{array}{c} \text{CH} \\ | \\ \text{CO}_2Et \end{array} + NaOH$ . On saponify-

ing and heating the resulting acid  $CO_2$  is evolved, and there results phenyl-glutaric acid  $Ph.CH.CH_2.CO_2H$  [138°]. Its silver salt,  $AgA'$ ,

$CH.CO_2H$  is amorphous (Michael, *J. pr.* [2] 35, 349; *Am.* 9, 118).

**n-Propyl ether**  $PrA'$ . (283°–284° i.V.) (A. a. K.). *S.G.*  $\frac{1}{2}$  1.0435 (Weger, *A.* 221, 76).

**Benzyl ether**  $C_6H_5.CH:CH.CO_2OCH_2C_6H_5$ . *Cinnamoin*. [39°]. Discovered by Plantamour (*A.* 27, 329; 30, 341) in balsam of Peru (Frémy, *A. Ch.* 70, 184; E. Kopp, *Compt. chim.* 1850, 140; Scharling, *A.* 74, 230; 97, 184; Kraut, *A.* 107, 208; Grimaux, *Z.* [2] 5, 157). Formed also by boiling dry sodium cinnamate with alcohol and benzyl chloride for some hours. Short prisms (from alcohol).

**Phenyl ether**  $C_6H_5.C_6H_5.CO_2C_6H_5$ : [78°]; (206°) at 15 mm. Formed by the action of cinnamoyl chloride upon phenol. By slow distillation it loses carbonic acid, giving stilbene  $C_6H_5.C_6H_4.C_6H_5$  (Anschütz, *B.* 18, 1945; *C. J.* 47, 898).

**p-Tolyl ether**  $C_6H_4(C_6H_5).CO_2C_6H_5$ : [101°]; (230°) at 15 mm. (A.). By slow distillation it yields s-phenyl-tolyl-ethylene (A.).

**Phenylpropyl ether**  $C_6H_5.C_6H_4.CO_2CH_2CH_2CH_2C_6H_5$ . Occurs in storax (Miller, *A.* 189, 853), and is also formed by treating styracon bromide with zinc and  $H_2SO_4$ .

**Thymyl ether**  $C_6H_5.C_6H_4.CO_2C_{10}H_{15}$ : [70°]; (240°) at 15 mm. (A.).

( $\beta$ )-**Naphthyl ether**  $C_{10}H_7.C_6H_5.CO_2C_{10}H_7$ : [102°]. By distillation  $CO_2$  is split off with formation of s-phenyl-naphthyl-ethylene (A.).

**Cinnamyl ether**  $C_6H_5.CH:CH.CO_2OCH_2CH_2CH_2C_6H_5$ . *Styracin*. [44°]. *S.* (ether) 38; *S.* (alcohol of *S.G.* 825) 83 at 78°; 5 at 15°. Occurs in liquid storax (Bonastre, *J. Ph.* 1881, 398; E. Simon, *A.* 81, 265; E. Kopp, *Compt. chim.* 1850, 140; Toel, *A.* 70, 1; Strocker, *A.* 70, 10; 74, 112; Wolff,

**A. 75, 297**; Plantamour, *A. 27*, 329; 30, 341; Gössmann, *A. 99*, 376; Scharling, *A. 97*, 90, 174; W. v. Miller, *N. Rep. Pharm.* 24, 1; *A. 188*, 200; 189, 344). Needles or prisms (from alcohol). Chlorine forms a viscid tetra-chloro-derivative  $C_{10}H_6Cl_4O_2$ . Br forms  $C_{10}H_6Br_2O_2$  [151°] and  $C_{10}H_6Br_4O_2$ .

**Chloride**  $C_9H_7CH:CH.CO.Cl$ . [36°]. (170°) at 58 mm. Prisms (Cahours, *A. Ch.* [3] 23, 341; Rostowski, *A. 178*, 214 (Claisen a. Antweiler, *B. 13*, 2123).

**Cyanide**  $C_9H_7CH:CH.CO.CN$ . [115°]. Prisms. Sol. ether,  $CHCl_3$ ,  $C_6H_6$ , and  $CS_2$ ; v. sl. sol. water. Prepared from the chloride by the action of silver cyanide. On saponification it gives cinnamoyl-formic acid.

**Anhydride**  $(C_9H_7CH:CH.CO)_2O$ . [127°]. (Gerhardt, *A. Ch.* [3] 37, 285; *A. 87*, 76). Crystalline.

**Amide**  $C_9H_7CH:CH.CO.NH_2$ . [142°]. (v. Rossum, *Z. 1866*, 362). — ( $C_9H_7CH:CH.CO.NH$ ). Ug.

**Anilide**  $C_6H_5CH:CH.CO.NPh$  (Cahours, *A. 70*, 43). Slender needles.

**Diphenylamide**  $C_6H_5CH:CH.CO.NPh_2$ . [153°] (Bernthsen, *B. 20*, 1554). Needles.

**Nitrile**  $C_9H_7CH:CH.CN$ . [112°]. (255°). From the amide and  $PCl_5$ . Also from cinnamic acid and lead sulphocyanide at 190° (Kruss, *B. 17*, 1768).

**Cinnamic acid dibromide v. Di-bromo-phenyl-propionic acid.**

**Cinnamic acid hydrobromide v. Bromo-phenyl-propionic acid.**

**Cinnamic-acid-di-nitrite**

$C_9H_7CH_2(NO_2)_2.CO.H$ . *Phenyl-di-nitro-propionic acid*. Colourless crystals. Formed by direct combination of cinnamic acid with  $N_2O_5$ . Very unstable. By treatment with water or alcohol it evolves  $CO_2$  and yields phenyl-nitro-ethylene  $C_6H_5CH:CH(NO_2)$  (Gabriel, *B. 18*, 2438).

**p-Aldehyde-cinnamic acid**

$C_9H_7(CHO)(CH:CH.CO.H)$ . [247°]. From terephthalic aldehyde,  $NaOAc$ , and  $Ac_2O$  by Perkin's reaction (Löw, *A. 231*, 374). Flat prisms or needles. Sl. sol. hot water, ether, or chloroform, more sol. glacial acetic acid. When sublimed it forms large plates. Salt.— $AgA$ .

**Ethyl ether**  $EtA'$ . Reduces ammoniacal  $AgNO_3$ . Gives by Perkin's reaction

$C_6H_5(CH:CH.CO.H)(CH:CH.CO.Et)$

(v. PHENYLENE-DI-ACRYLIC ACID). **Reactions.**—1. Reduces ammoniacal  $AgNO_3$  with difficulty.—2. Does not react with  $NaOAc$  and  $Ac_2O$ .—3. On nitration gives nitro-aldehyde-cinnamic acid (q. v.).

**Di-bromide**

$C_6H_5(CHO).CHBr.CHBr.CO_2H$ . [176°] (with decomposition). Prisms (from methyl alcohol). Insol. water; v. sol. ether, chloroform, and alcohol.

**p-Carboxy-cinnamic acid**

$C_6H_5(CO_2H)(CH:CH.CO_2H)$  [14]. Got by saponifying its ether. Powder, will not melt, but may be sublimed. Nearly insoluble in solvents. Does not combine with bromine in the cold. Forms a nitro-derivative.

**Dibromide**

$C_6H_5(CO_2H)(CHBr.CHBr.CO_2H)$ . **Di-bromo-carboxy-phenyl-propionic acid**. Formed at 100°. Will not melt. Sol. methyl alcohol, from which it may be crystallised.

**Mono-ethyl ether**

$C_9H_7(CO_2Et)(CH:CH.CO_2H)$  [220°]. From p-aldehyde-terephthalic ether,  $NaOAc$ , and  $Ac_2O$  by Perkin's reaction (Löw, *A. 231*, 369). Prisms (from ether).

**Other derivatives of cinnamic acid** are described as AMIDO-, BROMO-, CHLORO-, HYDRAZIDO-, NITRO-, SULPHIDO-, SULPHYDRO-, and SULPHO-CINNAMIC ACID. Oxy-cinnamic acid is described as COUMARIC ACID.

**CINNAMIC ALDEHYDE**  $C_9H_7O$  i.e.

$C_6H_5.C_6H_5.CH.O$ . Mol. w. 132. (129°). S.G.  $^{20}$  1.0197 (Brühl, *A. 235*, 18).  $\mu_D = 1.619$ .  $\mu_r = 1.683$ .

**Occurrence.**—In oil of cassia and oil of cinnamon, whence it may be extracted by shaking with  $NaHSO_3$  and distilling the resulting crystalline compound with aqueous  $Na_2CO_3$  (Perkin, *C. J.* 31, 403; cf. Mulder, *A. 34*, 147; Bertagnini, *A. 85*, 271).

**Formation.**—1. By oxidising cinnamyl alcohol with the aid of platinum black (Strecker, *A. 93*, 370).—2. By distilling calcium formate with calcium cinnamate (Piria, *A. 100*, 105).

**Preparation.**—A mixture of benzoic aldehyde (10 pts.), acetic aldehyde (15 pts.), 10 pts. of 10 p.c. aqueous  $NaOH$ , and 900 pts. of water is allowed to stand for 8 or 10 days with frequent shaking at about 30°, the cinnamic aldehyde being finally extracted with ether (Chiozza, *A. 97*, 350; Peine, *B. 17*, 2109).

**Properties.**—Oil. Forms crystalline compounds with  $HCl$ ,  $HNO_3$ ,  $NaHSO_3$ ,  $KHSO_3$ , and  $NH_4HSO_3$  (Dumas a. Péligot, *A. 14*, 65).

**Reactions.**—With alcoholic  $NH_3$  it gives hydrocinnamide  $C_9H_7NH_2$  [106°]. With  $HCN$  it yields the nitrile of  $\alpha$ -oxy-phenyl-crotonic acid. With resorcin and dilute  $HCl$  it gives a resin in the cold (Michael a. Ryder, *Am. 9*, 134).  $HCl$  passed into a mixture of cinnamic aldehyde with phenyl mercaptan forms  $C_6H_5C_6H_4CH(SPh)_2$  [81°] (Baumann, *B. 18*, 885). With carbamic ether it forms  $Ph.C_6H_4CH(NH.CO_2Et)_2$  [135°-143°] (Bischoff, *B. 7*, 1079).

**Phenyl hydrazide**

$C_6H_5.C_6H_4CH:N.HC_6H_5$ : [163°], yellow plates (Fischer, *B. 17*, 575).

**Anilide**  $C_6H_5.C_6H_4CH:NC_6H_5$ : [109°],

yellow glistening plates. Very stable towards  $HCl$ . Forms crystallisable salts with acids (Doebner a. Miller, *B. 16*, 1665; Peine, *B. 17*, 2109).

**Di-methyl-amido-anilide**

$C_6H_5.C_6H_4CH:N.C_6H_5(NMe)_2$ : [141°]; yellow needles; sol. alcohol, sl. sol. cold ether (Nuth, *B. 18*, 574).

**Ethylene-di-amide**

$(C_6H_5.C_6H_4CH:N).C_6H_5$ : [110°]; tables, m. sol. ether (Mason, *B. 20*, 267).

**Di-bromide v.  $\alpha$ -Di-bromo-phenyl-propionic aldehyde.**

**CINNAMIC ALDOXIM**

$C_6H_5CH:CH.CH:NOH$ . *Phenyl-acrylic aldoxim*. [136°]. Fine silky needles. V. sol. alcohol, ether, acids, and alkalis, nearly insol. cold water and ligroin.

**Benzoyl derivative**  $C_6H_5.C_6H_4CH:NOBz$ . [125°]. White needles; sl. sol. cold alcohol and benzene, insol. water and ligroin (Bornemann, *B. 19*, 1512).

**CINNAMIC-CARBOXYLIC ACID** *v. Carboxy-*

CINNAMIC ACID.

**CINNAMIDOXIM**  $C_9H_9N_2O$  *i.e.*

$C_6H_5.CH:CH.C(OH)NH_2$ . *Phenyl-allenyl-amidoxim*. [93°]. Formed by direct combination of cinnam. nitrile with hydroxylamine. Rod-like prisms. Sol. hot, less sol. cold water, v. sol. alcohol, ether, and benzene, sl. sol. ligroin. Decomposed by long boiling with water.

Salts.— $BHCl$ : [155°], flat concentric prisms.— $B_2H_2Cl_2PtCl_4$ : concentric needles, sol. alcohol.

*Methyl ether*  $C_9H_9(NH_2)NOMe$ : [98°]; prisms; volatile with steam; v. sol. alcohol, ether, &c., nearly insol. cold water, more readily in hot.

*Ethyl ether*  $C_9H_9(CNH_2)NOEt$ : [83°]; like the preceding.

*Benzoyl derivative*  $C_9H_9(CNH_2)NOBz$ : [160°]; fine needles; v. sol. alcohol, more sparingly sol. benzene, chloroform, and ether, insol. cold water. On boiling with water it loses 1 mol.  $H_2O$ , giving phenyl-allenyl-azoxim-benz-enyl (Wolff, B. 19, 1507).

**CINNAMO-LACTONE** *v. Coumarin*.**CINNAMONE** *v. Di-benzylidene-acetone*.**CINNAOYL-ACETO-ACETIC ETHER**

$C_{11}H_{16}O_4$ , *i.e.*  $Ph.CH:CH.CO.CHAc.CO.Et$ . [40°]. From sodium aceto-acetic ether and cinnamoyl chloride (Fischer a. Kuzel, B. 16, 166). Crystalline grains (from ligroin).

*a-CINNAOYL-BUTYRIC ETHER* *v. Benzylidene-ethyl-aceto-acetic ether*, vol. i. p. 21.

**CINNAOYL-FORMIC ACID** *v. STYRYL-GLYOXYLIC ACID*.**CINNAMYL ALCOHOL**  $C_9H_{10}O$  *i.e.*

$C_6H_5.CH:CH.CH(OH)$ . *Styrone*. Mol. w. 134. [33°]. (254°) at 717 mm. S.G. 20° 1.0440.  $\mu_D^{20}$  1.582 at 20° (Brühl, A. 235, 16).  $R_D^{20}$  69.7 (in a 9 p.c. alcoholic solution) (Kanonnikoff; Nasim a. Bernheimer, G. 14, 153). Obtained by distilling styrac (cinnamyl cinnamate) with aqueous potash (Simon, A. 31, 274; Ramdohr, Z. Pharm. 1858, 113; J. 1858, 446; Tol, A. 70, 3). Long thin needles, smelling like hyacinths. Sl. sol. cold water, v. e. sol. alcohol and ether.

*Reactions*.—1. Oxidised by air and platinum black to cinnamic aldehyde; and by chromic acid mixture to cinnamic acid and benzoic aldehyde.—2. Boiling with aqueous KOH and  $PbO_2$  gives benzoic aldehyde.—3. Reduced by sodium amalgam in presence of much water to phenyl-propyl alcohol (Rugheimer, A. 172, 122). Reduced by (15 p.c.) sodium amalgam by heating with a little water for 3 days at 100° it forms styrene  $C_6H_6$  and methyl alcohol, as follows:  $Ph.CH:CH.CH(OH) + H_2 = Ph.CH:CH_2 + CH_3OH$  (Hatton a. Hodgkinson, C. J. 39, 319).—4. Aqueous  $HCl$  (S.G. 1.96) at 190° gives toluene and allyl-benzene (Tiemann, B. 11, 671).—5. Fuming  $H_2SO_4$  forms  $C_9H_9SO_3H$  (?) (Jacobsen, A. 146, 90).—6.  $B_2O_3$  forms cinnamyl oxide  $(C_9H_9)_2O$ , a heavy oil.

*Acetyl derivative*  $C_9H_9OAc$ . (245°).

**CINNAMYLAMINE**  $C_9H_9N$  *i.e.*

$C_6H_5.CH:CH.CH_2NH_2$ . (100°). From cinnamyl chloride and alcoholic  $NH_3$  at 100° (Ramdohr, Z. Pharm. 1858, 113; J. 1858, 448). According to Malbot (C. R. 105, 574) the chief product is di-cinnamyl-amine.— $BHCl$ : stellate groups of crystals.— $B_2H_2PtCl_4$ : sl. sol. cold water.

**CINNAMYL CHLORIDE**  $C_9H_9Cl$  *i.e.*

$C_6H_5.CH:CH.CH_2Cl$ . A liquid, obtained by passing  $HCl$  into cinnamyl alcohol.  $NaOEt$  converts it into oily  $C_9H_9OEt$  (Ramdohr, Z. Pharm. 1858, 113; J. 1858, 448).  $K_2S$  forms oily  $(C_9H_9)_2S$ .

**CINNAMYLIDENE-DIACETONAMINE** *v. vol. i. p. 28*.**CINNAMYLIDENE-DI-THIO-GLYCOLLIC ACID**

$Ph.CH:CH.CH_2(SCH_2CO_2H)_2$ . [143°]. Formed by the action of cinnamic aldehyde on thio-glycollic acid (Bongartz, B. 21, 481). White plates (from hot water). By the action of zinc-dust in an alkaline solution cinnamyl thio-glycollic acid is formed.

**CINNAMYL IODIDE**  $C_9H_9I$ . From cinnamyl alcohol and  $PI_2$ . Oil. Converted by alcoholic  $KCy$  into oily  $C_9H_9Cy$ .

**DI-CINNAMYL KETONE** *v. Di-benzylidene-acetone*.**CINNAMYL-METHYL KETONE** *v. Benzylidene acetone*.**CINNAMYL-PHENYL-KETONE** *v. Phenyl-cinnamyl-ketone*.**CINNAMYL-THIO-GLYCOLLIC ACID**

$Ph.CH:CH.CH_2S.CH_2CO_2H$ . [77°]. The compound obtained by the action of cinnamic aldehyde on thioglycollic acid when treated with zinc-dust in an alkaline solution yields this substance (Bongartz, B. 21, 481). White plates (from dilute alcohol).

**CINNOLINE**  $C_8H_8N_2$ , *i.e.*  $C_6H_5 \begin{matrix} \diagup CH:CH \\ \diagdown N=N \end{matrix}$ . This

base has not been isolated. The first of its derivatives prepared was oxy-cinnoline carboxylic

acid  $C_8H_7N_2 \begin{matrix} \diagup C(OH):C.CO_2H \\ \diagdown N=N \end{matrix}$  obtained by warming

*o*-diazophenyl-propionic acid with water (Richter, B. 16, 677; v. also Widman, B. 17, 722).

**CINNYL**. A name sometimes applied to the radicle cinnamyl  $Ph.CH:CH.CH_2$ .

**CIRCULAR POLARISATION** *v. Physical methods*.

**CITRACETIC ACID**  $C_6H_8O_6$ . An acid said to be formed, together with aconitic acid, by treating bromo-acetic ether with sodium (Bayer, A. 135, 306).— $Ba_2A'''$ : 2aq: gummy.— $Pb_2A'''$ : 2aq.

**CITRA-DI-BROMO-PYROTARTARIC ACID** *v. Di-bromo-pyrotartaric acid*.**CITRA-CHLORO-PYROTARTARIC ACID** *v. Chloro-pyrotartaric acid*.**CITRACONANIL** *v. Phenylimide of Citraconic acid*.

**CITRACONIC ACID**  $C_8H_8O_6$ . Mol. w. 180. [80°]. S.G. 1.6. S. 238.  $R_D^{20}$  44.68 (in a 7 p.c. aqueous solution) (Kanonnikoff, J. pr. [2] 32, 497). H.C. 477867 (Longuiné, C. R. 106, 1291). Heat of solution: 2793 (Gal a. Werner, Bl. [2] 47, 159). Heat of neutralisation: 27082 (G. a. W.).

*Formation*.—1. The anhydride is the chief portion of the distillate obtained by heating citric acid. It rapidly combines with water (Lassaigne, A. Ch. [2] 21, 100; Robiquet, A. Ch. 75, 78; Liebig, A. 26, 119, 152; Gottlieb, A. 77, 265; Baup, A. Ch. [3] 33, 192; Kämmerer, A. 170, 191; Wilm, A. 141, 29).—2. By the distillation of itaconic acid (Crasso, A. 84, 68), of lactic acid (Engelhardt, A. 70, 246), of citramalic

acid (Carius, *A.* 129, 160), and of oxypyrotartaric acid (Demarçay, *C. R.* 82, 1337).

**Properties.**—Monoclinic four-sided prisms. Deliquescent. V. sol. water, alcohol, and ether. Volatile with steam. By dry distillation it is partially resolved into its anhydride.

**Reactions.**—1. *Sodium amalgam* in presence of water reduces it to pyrotartaric acid.—2. *Bromine* unites with it in the cold, forming citra-di-bromo-pyrotartaric acid (Kekulé, *J.* 1862, 318).—3. *Fuming hydric bromide* unites with it even in the cold, forming citra-bromo-pyrotartaric acid.—4. *Electrolysis* of the potassium salt forms allylene  $\text{CH}_2\text{C}(\text{CH}_3)=\text{CH}_2$ .—5. *Water* at 120° changes it to the isomeric itaconic acid.—6. *Boiling dilute HNO<sub>3</sub>* forms mesaconic acid.—7. *Chlorine* acting on sodium citraconate in aqueous solution forms chloro-citramalic, chloromethacrylic, and tri-chloro-isobutyric acids and tri-chloro-acetone (Gottlieb, *J. pr.* [2] 12, 1; Morawski, *J. pr.* [2] 12, 369).

**Salts.**— $\text{NH}_4\text{HA}$ ,— $\text{CaA}$  aq.— $\text{CaH}_2\text{A}$ , 3aq.  $\text{CaA}$  5aq (Kämmerer, *A.* 148, 326).— $\text{SrH}_2\text{A}$ , 3aq.— $\text{BaH}_2\text{A}$ , aq.: silky needles.— $\text{BaA}$  2aq (Kämmerer, *A.* 170, 191; Petri, *B.* 14, 1634).— $\text{PbH}_2\text{A}$ ,— $\text{PbA}$ ,— $\text{PbA}$  2aq.— $\text{PbA}$   $\cdot$   $\text{PbO}$ .— $\text{AgHA}$ ,— $\text{AgA}$ ,— $\text{AgA}$  aq.: hexagonal crystals.

The acid aniline salt  $\text{HA} \cdot \text{NH}_2\text{Ph}$  loses  $\text{H}_2\text{O}$  when its aqueous solution is allowed to stand for a few days, and deposits crystals of the acid anilide  $\text{CO}_2\text{H} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{NPh}$ .

The neutral aniline salt when boiled with water gives the phenyl-imide  $\text{C}_6\text{H}_4(\text{CO})_2\text{NPh}$ .

The ethyl-aniline and methyl-aniline salts do not give anilides when heated. The same is the case with  $\text{C}_6\text{H}_4\text{NMe}$ , and  $\text{C}_6\text{H}_4\text{NEt}$  salts.

The ethyl derivatives of *p*-toluidine behave exactly like the corresponding aniline compounds.

*Di-phenyl-amine citraconate* is only formed at 100°, since the  $\text{Ph}_2\text{NH}$  separates completely on cooling (Michael, *Am.* 9, 194).

**Methyl ether**  $\text{MeA}$ , (212° i. v.). S. 3 at 15°. S.G.  $\frac{4}{15}$  1.1168;  $\frac{30}{20}$  1.1050.  $\mu_D$  1.4442;  $\mu_H$  1.4721 at 15.5°. From citraconic acid, methyl alcohol, and HCl (Perkin, *C. J.* 39, 555). From silver citraconate and MeI. Oil; pleasant odour.

**Ethyl ether**  $\text{EtA}$ , (232° i. v.). S.G.  $\frac{12}{15}$  1.051;  $\frac{20}{15}$  1.038. M.M. 20.499 (Perkin, *C. J. Proc.* 8, 99).  $\mu_D$  1.4397;  $\mu_H$  1.4659 at 16.5° (Gladstone). An alcoholic solution with sodium-aceto-acetic ether at 100° forms an oil  $\text{C}_8\text{H}_{10}\text{O}$ , (174°) at 26 mm. (Michael, *J. pr.* [2] 35, 354; *Am.* 9, 118).

**Chloride**  $\text{C}_6\text{H}_4(\text{COCl})_2$  (95°) at 17.5 mm. S.G.  $\frac{15}{15}$  1.408. From the acid and  $\text{PCl}_5$  (Strecker, *B.* 15, 1640).

**Anhydride**  $\text{C}_6\text{H}_4\text{O}_2$ , [7°]. (214° i. v.). S.G.  $\frac{14}{15}$  1.241 (Anschütz, *B.* 13, 1642; 14, 2788). Partially converted by distillation into xeronic anhydride (Fittig, *A.* 188, 64). Thiourea at 130° converts it into  $\text{NH}_2\text{CS.NH.CO.C}_6\text{H}_4\text{CO}_2\text{H}$  [225°] (Pike, *B.* 6, 1106).

**Amide**  $\text{C}_6\text{H}_4\text{O}_2(\text{NH}_2)_2$ . Thin colourless tables, sol. water, decomposes at about 186° (Strecker, *B.* 15, 1640).

**Imide**  $\text{C}_6\text{H}_4\text{O}_2(\text{NH})$ , [110°]. Formed by distilling acid ammonium citraconate (Gottlieb, *A.* 77, 274; Ciamioian, *A.* Dennstedt, *G.* 12, 501). Needles (from water). Br forms  $\text{C}_6\text{H}_4\text{BrO}_2(\text{NH})$

[c. 181°] and  $\text{C}_6\text{H}_4\text{Br}_2\text{O}_2(\text{NH})$  [c. 144°].  $\text{C}_6\text{H}_4\text{O}_2\text{Na}$ g (Mendini, *G.* 15, 184).

**Anilide**  $\text{C}_6\text{H}_4\text{O}_2(\text{NHPH}_2)$ : [176°], long flat needles, sol. alcohol and ether, slightly in water (Strecker, *B.* 15, 1639).

**Acid anilide**  $\text{CO}_2\text{H} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{NHPH}_2$ . *Citraconanilic acid*. Formed spontaneously by allowing the aqueous solution of the acid aniline salt to stand for a few days. Large trimetric prisms or long needles.

**Phenylimide**  $\text{C}_6\text{H}_4\langle\text{CO}\rangle\text{NPh}$ . *Citraconanil*: [98°], formed by boiling aniline and citraconic acid in aqueous solution (Michael & Palmer, *B.* 19, 1375; *Am.* 9, 180).

**p-Chloro-phenylimide**  $\text{C}_6\text{H}_3\text{ClO}_2\text{NC}_6\text{H}_4\text{Cl}$ , [114°]. From the preceding and Cl (Morawski & Klaudy, *M.* 8, 399).

**Bromo-phenylimide**  $\text{C}_6\text{H}_3\text{BrO}_2\text{NC}_6\text{H}_4\text{Br}$ , [118°]. From the phenylimide and Br (M. a. K.).

**Di-nitro-phenylimide**  $\text{C}_6\text{H}_2\text{Cl}_2\text{O}_2\text{NC}_6\text{H}_2(\text{NO}_2)_2$ , [120°]. From the preceding,  $\text{HNO}_3$ , and  $\text{H}_2\text{SO}_4$  (Gottlieb, *A.* 85, 21).

**Acid toluidine**  $\text{CO}_2\text{H} \cdot \text{C}_6\text{H}_3 \cdot \text{CO}_2\text{NHC}_6\text{H}_4$ , [166°]. Formed by warming an aqueous solution of acid *p*-toluidine citraconate.

**p-Tolylimide**  $\text{C}_6\text{H}_3\text{ClO}_2\text{NC}_6\text{H}_4\text{Me}$ , [115°].

(a) *Naphthylimide*  $\text{C}_{10}\text{H}_7\text{O}_2\text{NC}_{10}\text{H}_7$ , [142°]. (360°). Yellow plates, sol. most solvents, insol. conc.  $\text{HCl}$ aq (Morawski & Glaser, *M.* 9, 286).

(b) *Naphthylimide*  $\text{C}_{10}\text{H}_7\text{O}_2\text{N}$ , [110°]. From citraconic acid and (b)-naphthylamine at 175° (M. a. G.). Pale yellow needles.

**m-Carboxy-phenylimide**  $\text{C}_6\text{H}_3\langle\text{CO}\rangle\text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{CO}_2\text{H}$ , [218°]. Formed by boiling *m*-amido-benzoic acid with an aqueous solution of citraconic acid. Prismatic needles, sol. hot alcohol and water, sol. dilute alkalis.

**Phenyl-hydrazide**  $\text{C}_6\text{H}_4\langle\text{CO}\rangle\text{N} \cdot \text{HPh}$ , [160°]. Bright yellow needles; sl. sol. cold, v. sol. hot, water.

**Isomerides of Citraconic Acid v. Itaconic acid, Mesaconic acid, Crotaconic acid, and Ethylidene-malonic acid.**

**Constitution of Citraconic acid.**—Citraconic acid stands to mesaconic acid in the same relation that maleic acid does to fumaric acid. The formation of allylene by the electrolysis of citraconic and mesaconic acids indicates the presence of a methyl group, so that citraconic acid is methyl-maleic acid, while mesaconic acid is methyl-fumaric acid. On the other hand, itaconic acid is said to give isopropylene  $\text{CH}_3\text{C}(\text{CH}_3)=\text{CH}_2$  on electrolysis.

Citraconic and maleic acids differ from the *allo*-isomerides in combining vigorously with halogens and HBr. The ethers of citraconic and maleic acids have higher boiling-points than those of mesaconic and fumaric acids, the difference being much greater between the methyl than the ethyl ethers.

On the other hand, (a)-coumaric ethers have lower boiling-points than (b)-coumaric ethers.

Citraconic acid with  $\text{PCl}_5$  gives mesaconyl chloride, (a)-coumaric acid with  $\text{PCl}_5$  gives (b)-coumaryl chloride (Petri, *B.* 14, 1634).

The indices of refraction of the citraconic

and mesaconic ethers are nearly the same for the red end of the spectrum, but the mesaconic ethers refract the violet rays more powerfully.

The ethers of citraconic, maleic, and (a)-coumaric acids contract in volume on changing to the more stable isomerides. The acid aniline salts of citraconic and maleic acids readily change, especially when their solution is evaporated at 100°, into phenylimides; the corresponding salts of mesaconic and fumaric acids are not affected (Perkin, *C. J.* 39, 561).

The initial velocity of etherification is 29.3 for itaconic acid, 57.9 for mesaconic acid, and 47.4 for citraconic acid (Menschutkin, *J. R.* 13, 527; *B.* 14, 2630).

**CITRAMALIC ACID** *v.* OXY-PYROTARTARIC ACID.

**CITRANILIC ACID** *v.* Phenylimide of CITRIC ACID.

**CITRATARTARIC ACID** *v.* DI-OXY-PYROTARTARIC ACID.

**CITRAZIC ACID** *v.* DI-OXY-PYRIDINE-CARBOXYLIC ACID.

**CITRENE** *v.* TERPENES.

**CITRIC ACID**  $C_6H_8O_7$ , *i.e.*

$CO_2H.CH_2.C(OH)(CO_2H).CH_2.CO_2H$ . [147°] (Grimaux a. Adam). *S.G.* 1.54. *S.* 125 at 15°; 200 at 100°. *S.* (of  $C_6H_8O_7$  aq in 80 p.c. alcohol) 87 at 15°; *S.* (of  $C_6H_8O_7$  in absolute alcohol) 75.9 at 15°; *S.* (of  $C_6H_8O_7$  in ether) 2.26 (Bourgoin, *Bl.* [2] 29, 244); *S.* (of  $C_6H_8O_7$  in ether) 9.1 (Lippmann, *B.* 12, 1650). *H.F.* 354,000 (*v.* Rechenberg).

**Occurrence.**—In lemons, oranges, cranberries, cowberries, and sundew (*Drosera intermedia*); together with malic acid in red currants, gooseberries, whortleberries, raspberries, and cloudberries (*Rubus Chamamorus*); together with both malic and tartaric acids in tamarinds and mountain ash berries (Scheele, *Opuscula*, 2, 181; Berzelius, *A. Ch.* 94, 171; [2] 52, 424, 432; 67, 303, 70, 215; Robiquet, *A. Ch.* [2] 65, 68; Liebig, *A.* 5, 134; 26, 119, 152; 44, 57; Marchand, *J. pr.* 23, 60; Cahours, *A. Ch.* [3] 19, 498; Pebal, *A.* 82, 78; 98, 67; Tilley, *J. Ph.* 13, 305; Perret, *Bl.* [2] 5, 42; Warrington, *C. J.* 23, 925; Stein, *B.* 12, 1603; Kossovich, *C. C.* 1887, 1157). Occurs also in certain plants, *e.g.* celandine (Haitinger, *M.* 2, 485), leaves of the wild cherry (Rochleder, *Z.* [2] 6, 176), *Lupinus luteus*, *Vicia sativa* (vetch), *Vicia Faba*, *Pisum sativum* (peas) and white beans (*Phaseolus*) (Ritthausen, *J. pr.* [2] 29, 357). Occurs as lime and potash salt in tobacco, and in the juice of lettuce. Occurs in the root and leaves of madder (Rochleder, *A.* 80, 322; Willigk, *A.* 82, 343), in beet-root (Michaelis, *J.* 1851, 394; *J. pr.* 54, 184; Schrader, *A.* 121, 370), and in young vines (Wittstein, *J.* 1857, 520; *Vier. ph. Pharm.* 6, 192).

**Synthesis.**— $\alpha$ -s-Di-chloro-acetone combines with hydrogen cyanide forming  $(CH_3Cl)_2C(OH).CN$  which is converted by saponification into  $(CH_3Cl)_2C(OH).CO_2H$ , whence  $KOCy$  readily forms  $(CN.CH_2)_2C(OH).CO_2H$  which is converted by treatment with  $HCl$  into citric acid (Grimaux a. Adam, *A. Ch.* [5] 23, 856; *C. R.* 90, 1252).

**Preparation.**—Lemon juice is allowed to undergo incipient fermentation, and is then boiled with chalk and lime. The *ppd.* calcium

citrate is decomposed by an equivalent quantity of  $H_2SO_4$ .

**Properties.**—Usually crystallises in efflorescent trimetric prisms (containing aq) *a:b:c* = -6068:1:4106. Different specimens of crystallised citric acid when powdered and left over  $H_2SO_4$  lose water at very different rates (Grosjean, *C. J.* 43, 331). From boiling solutions citric acid separates in anhydrous crystals (Sarandinaki, *B.* 5, 1101). Crystals containing 2aq may sometimes be obtained (Cloeze). Lime water produces little or no *pp.* in the cold, but calcium citrate is *ppd.* on boiling. Calcium citrate is insoluble in  $KOH$ ; it dissolves in  $NH_4Cl$ , but is reprecipitated on boiling. Citric acid differs also from tartaric acid in not forming an insoluble acid potassium salt. Boiling, strongly alkaline, permanganate is reduced by citric acid to manganate only, the liquid becoming green, whereas in the case of tartaric acid the reduction proceeds further, the liquid becoming brown (Chapman a. Smith, *Laboratory*, 1, 39; cf. Wimmel, *Z.* [2] 5, 286).  $FeCl_3$  gives a light yellow *pp.* in a hot solution of an alkaline citrate; the *pp.* dissolves in excess of the citrate (Kämmerer, *Fr.* 8, 298). Silver citrate dissolves in hot water without blackening. Conc.  $K_2Cr_2O_7$  aq is blackened in the cold by tartaric acid but not by citric acid.

**Estimation** (in lemon juice).—The juice is neutralised with  $Na_2CO_3$ ,  $CaCl_2$  is added, and the liquid boiled. The *pp.* is collected and washed. The filtrate and washings are treated with  $NH_3$  and evaporated to a small bulk. Some more calcic citrate then separates (Grosjean, *C. J.* 43, 332; cf. Fleischer, *Ar. Ph.* [3] 5, 97; Allen, *C. N.* 32, 277; Creuse, *Ph.* [8] 2, 547). A second concentration may then be effected, when a third quantity sometimes separates. Turmeric is better than litmus as an indicator in alkalimetric experiments with citric acid (F. Watts, *S. C. I.* 5, 214).

**Reactions.**—1. By heat it is split up at 175° into  $H_2O$  and aconitic acid  $C_6H_4O_6$ , which on dry distillation again splits up into  $CO$ , itaconic acid  $C_5H_4O_6$ , citraconic anhydride  $C_5H_4O_5$ , and acetone.—2. By heating with water (10 pts.) at 160° it is split up into itaconic acid and  $CO$  (Markownikoff a. Purgold, *Z.* [2] 3, 264).—3. Citric acid (100 g.) heated with water (50 g.) and sulphuric acid (100 g.) for 5 hours gives aconitic acid which separates on cooling (Hentschel, *J. pr.* [2] 35, 206). 100 g. citric acid heated with 100 g. water and 5 g.  $H_2SO_4$  at 170° give aconitic and itaconic acids (Pawollek, *A.* 178, 152).—4. Conc.  $H_2SO_4$  at 40° gives off  $CO$ ,  $CO_2$ , and acetone, and forms an acid whose acid barium salt is  $(C_6H_3SO_4)_2Ba$ , and is converted by baryta-water into  $(C_6H_3SO_4)_2Ba$  (Wilde, *A.* 127, 170).—5. On dry distillation with glycerin, it gives, besides acetone, acrolein,  $CO$ , and  $CO_2$ , a distillate containing the pyruvic ether of glycidic  $CH_2.CH.CH_2.CO.CO.CO_2CH_3$ . [82°]. (241°)

(De Clermont a. Chautard, *C. R.* 105, 520).—6. Conc.  $HCl$  aq at 150° gives aconitic acid; at 200° it also forms diacetic acid  $C_6H_8O_8$ , and gives off  $CO$  and  $CO_2$  (Hergt, *J. pr.* [2] 8, 378).—7. An aqueous solution mixed with yeast and chalk and exposed to the air at 25° forms acetic acid and

butyric acids (How, *C. J.* 5, 1, Personne, *C. R.* 36, 197).—8. *Chlorine* acting on a conc. aqueous solution of sodium citrate forms hexa-chloro-acetone and chloroform. Br acts in the same way (Cloeze, *C. R.* 53, 1120).—9. *Potash-fusion* gives oxalic and acetic acids (Liebig, *A.* 26, 158). 10. Acetone is formed by distilling sodium citrate with lime (Freidl, *M.* 4, 151).—11. Anhydrous citric acid is converted by a mixture of fuming  $\text{HNO}_3$  (1 pt.) and  $\text{H}_2\text{SO}_4$  (2 pts.) into the nitrate  $\text{C}_6\text{H}_5(\text{ONO}_2)(\text{CO}_2\text{H})_2$ , erroneously called nitro-citric acid. It is insol. ether, and forms insoluble salts  $\text{Ba}_2\text{A}'''$ , and  $\text{Pb}_2\text{A}'''$ , (Champion a. Pellet, *Bl.* [2] 24, 448).—12. Citric acid (1 mol.) heated with *glycerin* (1 mol.) at  $100^\circ$  forms glyceryl citrate  $\text{C}_6\text{H}_5\text{C}_3\text{H}_7\text{O}_8$ , a glassy mass, insol. water (Bemmelen, *J. pr.* 69, 84). Excess of glycerin at  $170^\circ$  gives so-called citro-diglycerin  $\text{C}_{12}\text{H}_{21}\text{O}_{16}$ (?).—13. Citric acid (1 mol.) heated with *mannite* (1 mol.) at  $140^\circ$  forms citromannitan  $\text{C}_{12}\text{H}_{21}\text{O}_{16}$ , (Bemmelen, *J.* 1858, 435). Excess of citric acid (2 mols.) heated with mannite at  $150^\circ$  forms ditromannitan  $\text{C}_{12}\text{H}_{21}\text{O}_{16}$ . Both bodies are amorphous.

**Salts.**— $\text{NH}_4\text{HA}'''$ : triclinic crystals. —  $(\text{NH}_4)_2\text{HA}'''$ . S.G.  $\frac{1}{2}$  1.479 (Clarke, *Am.* 2, 174). —  $(\text{NH}_4)_3\text{A}'''$ : deliquescent. Ferric and aluminium oxides, freshly precipitated, dissolve in a solution of ammonium citrate, and from the solutions when evaporated salts of the general type  $\text{C}_6\text{H}_5\text{O}_7\text{H}(\text{NH}_4)_2(\text{C}_6\text{H}_5\text{O}_7)_2\text{M}_2\text{H}_2\text{O}$  crystallise out. Similarly magnesium, manganese, nickel, cobalt, zinc, copper, and mercuric oxides dissolve in ammonium citrate to form salts of general type  $[\text{C}_6\text{H}_5\text{O}_7(\text{NH}_4)_2]_2\text{M}$  generally with 1 mol.  $\text{H}_2\text{O}$ . Solutions of these salts are not precipitated by ammonia, the alkaline hydroxides and carbonates, but completely precipitated by  $\text{H}_2\text{S}$  or ammonium sulphide. The oxides and carbonates of Ba, Sr, and Ca decompose boiling solutions of ammonium citrate forming insoluble pps. of the corresponding salts  $\text{Ca}_2\text{A}'''$ , &c. (Landrin, *A. Ch.* [5] 25, 233; *C. R.* 86, 1336). —  $(\text{NH}_4)_2\text{A}'''$  (Heusser, *P.* 88, 121). —  $\text{Li}_2\text{A}'''$  (?) (Thomson, *Ph.* [3] 13, 783). —  $\text{NaHA}'''$  aq.: needles. —  $\text{Na}_2\text{A}'''$   $\frac{2}{3}$  aq. S.G.  $\frac{1}{4}$

1.858 (Clarke, *Am.* 2, 174; Kämmerer, *A.* 148, 294; 170, 176). Trimetric prisms or groups of silky needles. —  $\text{Na}_2\text{A}'''$  2aq (Heldt, *A.* 47, 157). —  $\text{KHA}'''$  2aq. —  $\text{K}_2\text{HA}'''$ . —  $\text{K}_2\text{A}'''$  aq. —  $\text{K}_3(\text{NH}_4)_2\text{HA}'''$ . —  $\text{K}_3(\text{NH}_4)_2\text{A}'''$ . —  $\text{K}_3\text{Na}_2\text{A}'''$   $\frac{6}{5}$  aq.  $\text{K}_3\text{Na}_2\text{A}'''$  11aq. —  $\text{Ti}_2\text{A}'''$  (Kuhlmann, *C. R.* 65, 607). —  $\text{Ba}_2\text{A}'''$  7aq: amorphous pp. —  $\text{Ba}_3\text{A}'''$  5aq: groups of minute needles, formed by boiling the above with water. —  $\text{Ba}_3\text{A}'''$  3 $\frac{1}{2}$  aq: minute monoclinic prisms, formed by treating either of the two preceding salts with ammonia. —  $\text{Sr}_2\text{A}'''$  6aq: minute silky needles. —  $\text{Sr}_2\text{A}'''$  2aq. —  $\text{Sr}_2\text{H}_2(\text{C}_6\text{H}_5\text{O}_7)_2$  11aq. —  $\text{Sr}_2\text{H}_2(\text{C}_6\text{H}_5\text{O}_7)_2$  2 $\frac{1}{2}$  aq. —  $\text{Ca}_2\text{A}'''$  4aq. From  $\text{Na}_2\text{A}'''$  and  $\text{CaCl}_2$  pps. changed in water at  $100^\circ$  into minute transparent needles. —  $\text{Ca}_2\text{A}'''$  7aq. —  $\text{CaHA}'''$  2aq. —  $\text{Mg}_2\text{H}_2(\text{C}_6\text{H}_5\text{O}_7)_2$  8aq. —  $\text{Mg}_2\text{A}'''$  9aq. —  $\text{Mg}_2\text{A}'''$  5 $\frac{1}{2}$  aq. —  $\text{Mg}_2\text{A}'''$  7aq. —  $\text{Mg}_2\text{H}_2(\text{C}_6\text{H}_5\text{O}_7)_2$  13aq. —  $\text{Mg}_2\text{H}_2(\text{C}_6\text{H}_5\text{O}_7)_2$  8aq. —  $\text{Mg}_2\text{A}'''$  14aq. —  $\text{Mg}(\text{NH}_4)_2\text{A}'''$  2aq (Landrin, *C. R.* 86, 1836). —  $\text{Zn}_2\text{A}'''$  2aq. —  $\text{Zn}_2\text{H}_2(\text{C}_6\text{H}_5\text{O}_7)_2$ . —  $\text{Zn}_2\text{H}_2\text{A}'''$  2aq. —  $\text{Zn}(\text{NH}_4)_2\text{A}'''$ . —  $\text{Cd}_2\text{A}'''$  1 $\frac{1}{2}$  aq. —  $\text{Cd}_2\text{A}'''$  10aq. —  $\text{Cd}_2\text{H}_2(\text{C}_6\text{H}_5\text{O}_7)_2$  18aq: needles. —  $\text{C}_6\text{H}_5(\text{C}_6\text{H}_5\text{O}_7)_2$  27aq. —  $\text{Cu}_2\text{C}_6\text{H}_5\text{O}_7$  3 $\frac{1}{2}$  aq: green

crystalline precipitate which is obtained by boiling a solution of cupric carbonate in citric acid. —  $\text{Cu}_2\text{H}_2(\text{C}_6\text{H}_5\text{O}_7)_2$  15aq: greenish pp. got by adding alcohol to the above solution. —  $\text{Cu}(\text{NH}_4)_2\text{A}'''$  2aq (Landrin, *C. R.* 86, 1336). —  $\text{Pb}_2\text{A}'''$  3aq: crystalline pp. from lead nitrate and  $\text{Na}_2\text{A}'''$ . —  $\text{Pb}_2\text{C}_6\text{H}_5\text{O}_7$  2aq: amorphous; got by heating the preceding with ammonia. —  $\text{Pb}_2\text{A}'''$  aq: amorphous pp. from alcoholic  $\text{Pb}(\text{OAc})_2$  and citric acid. —  $\text{PbHA}'''$ : crystals, v. sol. water. —  $\text{Pb}_2\text{A}'''$   $\text{Pb}_2\text{O}_3$  3aq (at  $100^\circ$ ) (Otto, *A.* 127, 175). —  $\text{Pb}_2\text{A}'''$   $\text{Pb}_2\text{O}_3$ . —  $\text{Hg}(\text{NH}_4)_2\text{A}'''$ . —  $\text{Co}_2\text{A}'''$  14aq: amorphous. —  $\text{Co}(\text{NH}_4)_2\text{A}'''$  4aq. —  $\text{Ni}_2\text{A}'''$  14aq: amorphous. —  $\text{Ni}(\text{NH}_4)_2\text{A}'''$  4aq. —  $\text{Mn}_2\text{A}'''$  2aq: crystalline powder formed by boiling citric acid with  $\text{MnCO}_3$  (Heldt); the following salts are formed at the same time (K.). Sodium citrate does not precipitate salts of manganese. —  $\text{MnHA}'''$  aq. —  $\text{Mn}_2\text{A}'''$  2aq: trimetric prisms. —  $\text{Mn}_2\text{H}_2(\text{C}_6\text{H}_5\text{O}_7)_2$  15aq. —  $\text{Mn}_2\text{H}_2(\text{C}_6\text{H}_5\text{O}_7)_2$  18aq. —  $\text{Mn}(\text{NH}_4)_2\text{A}'''$ . —  $\text{FeHA}'''$  aq: crystalline powder formed by boiling iron with aqueous citric acid. —  $\text{FeNaA}'''$ : apple-green scales (Rother, *Ph.* [3] 13, 629). —  $\text{Fe}(\text{OH})\text{NaA}'''$ : amorphous grass-green powder. —  $\text{FeNa}_2\text{H}_2\text{A}'''$ . —  $\text{FeNa}_2\text{H}_2(\text{PO}_4)_2\text{A}'''$ . —  $\text{FeA}'''$  1 $\frac{1}{2}$  aq: got by dissolving  $\text{Fe}(\text{OH})_3$  in citric acid. Light brown film. —  $\text{Fe}(\text{OH})\text{HA}'''$  2aq (Schiff, *A.* 125, 147). —  $\text{Fe}(\text{NH}_4)_2\text{A}'''$ : greenish-yellow mass. —  $\text{Fe}(\text{NH}_4)_2\text{HA}'''$ . —  $\text{Fe}(\text{NH}_4)_2\text{H}_2\text{A}'''$ . —  $\text{FeO}(\text{NH}_4)_2\text{A}'''$  4aq. —  $\text{FeA}'''(\text{NH}_4)_2$  8aq. —  $\text{Fe}(\text{NH}_4)_2(\text{C}_6\text{H}_5\text{O}_7)_2$  3aq (Méhu, *J.* 1873, 670). —  $\text{Fe}(\text{OH})(\text{NH}_4)_2\text{A}'''$  2aq. —  $\text{Al}(\text{OH})(\text{NH}_4)_2\text{A}'''$ . —  $\text{SmaA}'''$  6aq: amorphous pp. sol. ammonia. The ammoniacal solution does not become turbid on heating (Clève, *Bl.* [2] 43, 172). —  $\text{Y}_2\text{A}'''$  14aq. —  $\text{LaA}'''$  3 $\frac{1}{2}$  aq (Czudnowicz, *J.* 1860, 128; *J. pr.* 80, 31). —  $\text{CeA}'''$  3 $\frac{1}{2}$  aq. —  $\text{K}_2\text{SbA}'''$  2 $\frac{1}{2}$  aq: hard prisms grouped in tufts. —  $\text{BiA}'''$ : granular pp. obtained by boiling bismuth nitrate with citric acid (Rother, *Ph.* [3] 6, 764; Cavazzi, *G.* 14, 289). —  $(\text{BiO})(\text{NH}_4)_2\text{A}'''$ : obtained, together with the following body, by boiling the preceding with ammonia. —  $(\text{BiO})(\text{NH}_4)_2\text{HA}'''$ . —  $\text{BiA}'''4\text{Bi}(\text{OH})_3$ : gelatinous pp. —  $\text{BiA}'''(\text{NH}_4)_2$  3aq (Bartlett, *C. N.* 21, 28). —  $\text{FeA}'''$   $\text{BiA}'''(\text{NH}_4)_2$  3aq. —  $\text{Ag}_2\text{A}'''$ : powder; crystallises from water in needles. —  $\text{Ag}_2\text{HA}'''$  (Rönnefahrt, *J.* 1876, 562). —  $\text{Ag}_2\text{A}'''(\text{NH}_4)_2$  1 $\frac{1}{2}$  aq (Wöhler, *A.* 97, 18). —  $\text{Ag}_2\text{A}'''$  (?) (W.): got by heating  $\text{Ag}_2\text{A}'''$  at  $100^\circ$  in a current of hydrogen. —  $\text{Ag}_2\text{CaC}_6\text{H}_5\text{O}_7$ . — Telluro-citrate.  $\text{K}_2\text{A}'''$   $\text{TeO}_2$  aq: leaflets, v. sol. water; formed by adding citric acid to a solution of potassium tellurite and evaporating (Klein, *C. R.* 102, 47). — Boro-citrates. Boro-citric acid  $\text{H}_2\text{A}'''$   $\text{HBO}_3$  at  $80^\circ$  is formed by dissolving boric acid (1 mol.) in a solution of citric acid (2 mols.). It is a deliquescent mass. The boro-citrates are formed by dissolving boric acid in solutions of the citrates. The magnesium boro-citrates do not crystallise. —  $\text{Na}_2\text{A}'''3\text{HBO}_3$ . —  $\text{Na}_2\text{HA}'''2\text{HBO}_3$ . —  $\text{NaHA}'''$   $\text{HBO}_3$ . —  $\text{KHA}'''2\text{HBO}_3$ . —  $\text{K}_2\text{A}'''3\text{HBO}_3$ . —  $\text{KH}_2\text{A}'''$   $\text{HBO}_3$ . —  $\text{KH}_2\text{A}'''2\text{HBO}_3$ . —  $\text{Li}_2\text{H}_2\text{A}'''3\text{HBO}_3$ . —  $\text{MgH}_2\text{A}'''$   $\text{HBO}_3$ . —  $\text{MgH}_2\text{A}'''4\text{HBO}_3$ . —  $\text{Mg}_2\text{A}'''6\text{HBO}_3$  (Scheibe, *Ph.* [3] 11, 889). — Aniline salt  $\text{NPhH}_2\text{C}_6\text{H}_5\text{O}_7$ . Needles (Pebal, *A.* 82, 91). At  $145^\circ$  it changes to the phenylimide.  $\psi$ -Cumidine salt  $\text{C}_6\text{H}_5\text{Me}_2\text{NH}_2\text{H}_2\text{A}'''$  [188°] (Schneider, *B.* 21, 660).

*Methyl ether*  $\text{MeHA}'''$  (Demondésir, *A.* 80, 802).

**Di-methyl ether**  $\text{Me}_2\text{HA}'''$  (St. Evre, *A.* 60 325).

**Tri-methyl ether**  $\text{Me}_3\text{A}''$ . [79°]. (*c.* 285°); (176° at 16 mm.). Formed, together with the two preceding bodies, by passing HCl into a solution of citric acid in MeOH (St. Evre, *C. R.* 21, 1441). Triclinic crystals. Partly split up on distillation into  $\text{H}_2\text{O}$  and tri-methyl aconitate (271°).  $\text{PCl}_5$  gives oily  $\text{C}_3\text{H}_5\text{Cl}(\text{CO}_2\text{Me})_3$ .

**Acetyl-trimethyl ether**

$\text{C}_3\text{H}_5(\text{OAc})(\text{CO}_2\text{Me})_3$ . (281°); (171° at 15 mm.).

**Mono-ethyl ether**  $\text{EtHA}''$ . Formed by the action of sodium amalgam upon wet  $\text{Et}_3\text{A}'''$  (Claus a. Roennelshardt, *B.* 8, 866). Formed also by boiling citric acid with acetic ether (Kreitmaier, *B.* 8, 737). Thin prisms; v. sol. water, alcohol, and ether.— $\text{Na}_2\text{EtA}'''$  (at 100°); prisms.— $\text{Ag}_2\text{EtA}'''$ .

**Di-ethyl ether**  $\text{Et}_2\text{HA}''$ . (218° at 60 mm.). Formed, together with the preceding, by the action of sodium amalgam on wet citric ether.— $\text{NaEt}_2\text{A}'''$ : deliquescent. **Formation**.—(Conen, *B.* 12, 1653; Ruhemann, *C. J.* 51, 404).

**Tri-ethyl ether**  $\text{Et}_3\text{A}''$ . (218° at 60 mm.) (Ruhemann, *B.* 20, 799; *C. J.* 51, 404); (213° at 35 mm.); (263° at 300 mm.) (Conen, *B.* 12, 1653). S.G.  $\frac{4}{3}$  1.137 (*C.*).  $\mu_D$  1.4513.  $R_D$  105.09 (Brühl). Formed by heating citric acid with alcohol and  $\text{H}_2\text{SO}_4$ , or, better, by saturating an alcoholic solution of citric acid with HCl (Thénard, *Mém. d'Arcueil*, 2, 12; Malaguti, *A. Ch.* 63, 197; Dumas, *C. R.* 8, 528; Marchand, *J. pr.* 20, 318; Heldt, *A.* 47, 157; Demondeir, *C. R.* 33, 227; Pebal, *A.* 98, 67; Claus, *B.* 8, 867). Oil; v. sol. alcohol and ether. It boils with decomposition at 280°.

**Acetyl-tri-ethyl ether**

$\text{C}_3\text{H}_5(\text{OAc})(\text{CO}_2\text{Et})_3$ . (288°); (229° at 100 mm.), (214° at 40 mm.); S.G.  $\frac{4}{3}$  1.1459. By the action of strong aqueous  $\text{NH}_3$ , it is converted into the amide of di-oxy-pyridine-carboxylic acid (citraz-

$\text{imide})\text{N} \begin{array}{c} \text{C(OH):CH} \\ \diagup \quad \diagdown \\ \text{C(OH):CH} \end{array} \text{C-CONH}_2$  (Ruhemann, *B.* 20, 799; *C. J.* 51, 404; cf. Wislicenus, *A.* 129, 175). Yields a phenyl-hydrazide [128°].

**Tetra-ethyl ether**  $\text{C}_3\text{H}_5(\text{OEt})(\text{CO}_2\text{Et})_4$ . S.G.  $\frac{4}{3}$  1.1022.  $\mu_D$  1.4548.  $R_D$  119.97 (Brühl). Thick liquid. Bitter taste. (238° at 150 mm., and about 290° at 760 mm.). With  $\text{PCl}_5$  it gives aconitic ether (Conen, *B.* 12, 1653).

**Tri-n-propyl ether**  $\text{C}_3\text{H}_5(\text{OH})(\text{CO}_2\text{Pr})_3$ . (198°) at 13 mm.

**Acetyl-tri-n-propyl ether**

$\text{C}_3\text{H}_5(\text{OAc})(\text{CO}_2\text{C}_3\text{H}_7)_3$ . (205° at 13 mm.). When heated to 250°–280° the acetyl ethers readily split off acetic acid, yielding the corresponding ethers of aconitic acid (Anschütz a. Klingemann, *B.* 18, 1953).

**Mono-isoomyl ether**  $\text{C}_3\text{H}_5\text{HA}'''$  (Breunlin, *A.* 91, 318). —  $(\text{NH}_4)_2(\text{C}_3\text{H}_5\text{A}''')$ . —  $\text{NaH}(\text{C}_3\text{H}_5\text{A}''')$ . —  $\text{KH}(\text{C}_3\text{H}_5\text{A}''')$ . —  $\text{Pb}_2(\text{C}_3\text{H}_5\text{A}''')$ . —  $\text{CaH}_2(\text{C}_3\text{H}_5\text{A}''')$ . aq. laminae.

**Ethyl isoomyl ether**  $\text{C}_3\text{H}_5\text{EtHA}'''$ . Oil.

**Tri-phenylether**  $\text{C}_3\text{H}_5\text{O}(\text{CO}_2\text{Ph})_3$ . [125°]. From citric acid, phenol and  $\text{POCl}_3$  (Seifert, *J. pr.* [2] 81, 470).

**Mono-amide**  $\text{C}_3\text{H}_5\text{O}(\text{CO}_2\text{H})\text{CONH}_2$ . **Citronamic acid**. [188°]. Colourless crystals; extremely sol. water, less sol. alcohol, insol. ether and ligroin. Formed as a by-product in the

preparation of the tri-amide. By boiling with HCl, or by heating with 75 p.c.  $\text{H}_2\text{SO}_4$ , it is converted into citrazinic acid  $\text{C}_3\text{H}_5\text{NO}_4$ .—Salt.  $\text{C}_3\text{H}_5\text{O}_2\text{NAg}$ ; white pp.

**Di-amide**  $\text{C}_3\text{H}_5\text{O}(\text{CO}_2\text{H})(\text{CONH}_2)_2$ : **citro-diamic acid**: [158°]; white plates; v. sol. water, nearly insol. alcohol and ether. Formed as a by-product in the preparation of the tri-amide. By boiling with HCl, or by heating with 75 p.c.  $\text{H}_2\text{SO}_4$ , it is converted into citrazinic acid.— $\text{C}_3\text{H}_5\text{O}_2\text{N}_2\text{Ag}$ : crystalline pp.

**Tri-amide**  $\text{C}_3\text{H}_5\text{O}(\text{CONH}_2)_3$ : [210°–215°]; colourless crystals;  $\delta$ . (at 18°) = 2.7; (at 100°) = 33.3; insol. alcohol, ether, &c. Prepared by the action of strong aqueous  $\text{NH}_3$  (88) in the cold upon the tri-methyl ether of citric acid. By heating with HCl or with 75 p.c.  $\text{H}_2\text{SO}_4$ , it is converted into citrazinic acid (Behrmann a. Hofmann, *B.* 17, 2682).

**Tri-methyl amide**

$\text{C}_3\text{H}_5(\text{OH})(\text{CO}_2\text{NHMe})_3$ : [124°]; white prisms, v. sol. cold water.

**Phenylimide**  $\text{C}_3\text{H}_5(\text{OH})(\text{CO}_2\text{H})(\text{C}_6\text{H}_5\text{NPh})$ .

**Citranilic acid**. Formed by heating citric acid (1 mol.) with aniline (1 mol.) at 150° (Pebal, *A.* 82, 92). Crystalline spherules (from water).— $\text{AgC}_3\text{H}_5\text{NO}_4$ .— $\text{NPhH}_2\text{C}_3\text{H}_5\text{NO}_4$ .

**Dianilide**  $\text{C}_3\text{H}_5(\text{OH})(\text{CO}_2\text{H})(\text{CONPhH})_2$ . [150°]. Formed by boiling the di-phenylamide-imide with ammonia. Concentric groups of silky needles (from alcohol).

**Di-phenylamide-imide**

$\text{C}_3\text{H}_5(\text{OH})(\text{CONPhH})(\text{C}_6\text{H}_5\text{NPh})$ . Formed by heating the aniline salt of the phenylimide. Hexagonal plates; sol. alcohol.

**Tri-anilide**

$\text{C}_3\text{H}_5(\text{OH})(\text{CONPhH})_3$ . Formed by heating normal aniline citrate. Prisms (from alcohol). Insol. alkalis.

**p-Tolyl-imide**

$\text{C}_3\text{H}_5(\text{OH})(\text{CO}_2\text{H}) \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{array} \text{NC}_6\text{H}_4$ : [173°]; small white crystals; v. sol. alcohol, ether, and hot water, sl. sol. cold water. Formed by heating mono-p-toluidine citrate at 160°–170°.

**Di-p-tolylamide-imide**

$\text{C}_3\text{H}_5(\text{OH})(\text{CO}_2\text{NHC}_6\text{H}_4) \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{array} \text{NC}_6\text{H}_4$ : [205°]; small granular crystals; m. sol. alcohol and ether, insol. water. Formed by heating 1 mol. of citric acid and 2 mols. of p-toluidine for three hours at 160°–170°.

**Di-p-tolyl-di-amide**

$\text{C}_3\text{H}_5(\text{OH})(\text{CO}_2\text{NHC}_6\text{H}_4)_2(\text{CO}_2\text{H})$ : [161°]; small needles; sol. alcohol and ether, insol. water. Formed by heating the preceding compound with aqueous  $\text{NH}_3$ .

**Tri-p-tolyl-tri-amide**

$\text{C}_3\text{H}_5(\text{OH})(\text{CO}_2\text{NHC}_6\text{H}_4)_3$ : [189°]; silky white microscopic needles; sl. sol. alcohol, insol. water. Formed by heating 1 mol. of citric acid and 3 mols. of p-toluidine at 140°–145° (Gill, *B.* 19, 2352).

**Di-ψ-cumylamide-imide**

$\text{C}_3\text{H}_5(\text{OH})(\text{CO}_2\text{NHC}_6\text{H}_4\text{Me}) \begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{CO} \end{array} \text{NC}_6\text{H}_4\text{Me}$ . [178°]. The chief product of the action of ψ-cumidine (2 mols.) on citric acid (1 mol.) at 160° (Schneider, *B.* 21, 680). Prisms; v. sol. alcohol.

**Di-ψ-cumidide**

$\text{C}_3\text{H}_5(\text{OH})(\text{CO}_2\text{H})(\text{CO}_2\text{NHC}_6\text{H}_4\text{Me})_2$ . [194°]. Formed by treating the preceding with alkalis.— $\text{NaA}'$ . [236°].

*Tri-ψ-cumide*

$C_6H_4(OH)(CO.NH.C_6H_4.Me)_3$ ; [185°]; white powder, sl. sol. alcohol. Formed by heating citric acid (1 mol.) with ψ-cumidine (3 mols.).

*Benzide*

$C_6H_4(OH)(CO_2H) \begin{matrix} \diagup CO.NH.C_6H_4 \\ \diagdown CO.NH.C_6H_4 \end{matrix}$ . From benzidine and citric acid at 150°. Carbonises above 300°. Crystalline powder.

*Tolylene-diamide*

$C_6H_4(OH) \begin{matrix} \diagup C_6H_4.N \\ \diagdown CO.NH \end{matrix} C_6H_4.Me$ . [187°]. From citric acid and tolylene-diamine. [99°] at 130°. Minute crystals.

*Tri-nitro-anilide*

$C_6H_4(OH)(CO.NH.C_6H_4.NO_2)_3$ . [108°]. Formed by nitrating the anilide.

*Di-(β)-naphthyl-amide-imide*

$C_6H_4(OH)(CO.NHC_6H_4) \begin{matrix} \diagup CO \\ \diagdown CO \end{matrix} NC_{10}H_7$ ; [233°]. Formed by heating 1 mol. of citric acid with 2 mols. of (β)-naphthylamine, at 140°-150°. White six-sided plates. Sl. sol. alcohol, insol. water.

*Di-(β)-naphthyl-di-amide*

$C_6H_4(OH)(CO_2H)(CO.NHC_6H_4)_2$ ; [172°]. Formed by digesting the preceding body with conc. aqueous  $NH_3$  at 170°. Microscopic concentric needles. Insol. water. Weak acid reaction to litmus.—A'Ag.

*Tri-(β)-naphthyl-tri-amide*

$C_6H_4(OH)(CO.NHC_6H_4)_3$ ; [215°]. Formed by heating the di-naphthyl-amide-imide with (β)-naphthylamine (1 mol.) at 150°-170°. Microscopic prisms. V. sol. alcohol, insol. water.

*Di-(α)-naphthyl-amide-imide*

$C_6H_4(OH)(CO.NHC_6H_4) \begin{matrix} \diagup CO \\ \diagdown CO \end{matrix} NC_{10}H_7$ ; [194°]. Formed by heating 1 mol. of citric acid with 2 mols. of (α)-naphthylamine at 140°-150°. Six-sided plates (from benzene). V. sol. alcohol, ether, &c., insol. HClAq.

*Di-(α)-naphthyl-di-amide*

$C_6H_4(OH)(CO_2H)(CO.NHC_6H_4)_2$ ; [149°]. Formed by heating the preceding body with aqueous  $NH_3$  at 150°-160°. Small needles (from alcohol). A'Ag.

*Tri-(α)-naphthyl-tri-amide*

$C_6H_4(OH)(CO.NHC_6H_4)_3$ ; [129°]. Formed by heating the di-(α)-naphthyl-amide-imide with (β)-naphthylamine (1 mol.) at 150°-170°. Microscopic rhombic prisms (Hecht, B. 19, 2614).

**ISOMERIDE OF CITRIC ACID v. OXY-TRICARBALLYLIC ACID.****CITRIDIC ACID v. ACONITIC ACID.**

**CITRONELLOL**  $C_{10}H_{18}O$  (Gladstone, C. J. 25, 47) or  $C_{10}H_{16}O$  (Wright, O. J. 12, 318). (210°. 220°). The chief constituent of the oil of citronella (*Andropogon Nardus* or *Schœnanthus*), a grass cultivated in Ceylon. P.S., appears to form a mixture of terpenes and their polymerides. It combines with Br, forming a dibromide, which is split up by heat into  $H_2O$ , cymene, and HBr.

**CLADONIC ACID.** (β)-*Usnic acid*. [175°]. Occurs in *Cladonia rangiferina* (Stenhouse, A. 155, 60; Hesse, A. 117, 346). Yields betorcin on dry distillation. Cladonic acid is probably a mixture of usnic and barbatic acids (Paterno, G. 5, 113; 12, 231; Stenhouse, A. 203, 285).

**CLASSIFICATION. CHEMICAL.**—In the following article nothing more is attempted than to sketch the outlines of the methods by the employment of which a fairly satisfactory scheme of chemical classification may be attained. 'By the classification of any series of objects is meant the actual or ideal arrangement together of those which are like and the separation of those which are unlike; the purpose of this arrangement being primarily to disclose the correlations or laws of union of properties or circumstances, and secondarily to facilitate the operations of the mind in clearly conceiving and retaining in the memory the characters of the objects in question.'

The importance of classification in chemistry can scarcely be too much insisted upon. The fundamental object is to arrange the various kinds of matter with which chemistry is concerned in classes, so that the connexions between the properties and the composition of these kinds of matter shall be made apparent. Inasmuch as our knowledge of the connexions between the composition and the properties of different kinds of matter is being modified from day to day, it is evident that no system of chemical classification can be regarded at present as a final system. That we may draw the outlines of a scheme of chemical classification, it is necessary first of all to inquire what the objects are which the scheme is to include.

Chemistry concerns itself with the connexions between the properties and the composition of homogeneous kinds of matter; a homogeneous kind of matter being such that all the portions, however small, into which it can be divided, are possessed of the same properties as belong to the mass. But the properties of homogeneous kinds of matter are of two kinds; on the one hand, there are those properties which belong to, or which may be acquired by, the specified kind of matter considered apart from other kinds of matter; on the other hand, there are the properties which are exhibited by the specified kind of matter when it acts on, and is acted on by, other kinds of matter. Chemistry concerns itself more especially with the latter kind of properties. Another classification of the properties of homogeneous kinds of matter may be made; we may pay regard to those properties which are the sums of the properties of the parts of the specified mass of matter; or we may look to those properties which are dependent on the configurations of these parts. Any mass of matter may be conceived to be made up of a vast but finite number of minute particles, which, for the purposes of the investigation in hand, may be regarded as indivisible. These particles may or may not be possessed of the properties which distinguish the mass of matter under consideration; the properties of the mass may be the sum of the properties of the particles, or they may differ from the sum of these properties. In the latter case we assume that the properties of the mass depend, among other conditions, on the relative arrangement of the particles. The weight of any mass of matter, i.e., the force with which the matter is attracted towards the

<sup>1</sup> Stanley Jevons (in *Principles of Science*, II. 348, 1st ed.) modifying Huxley's definition given in *Lectures on the Elements of Comparative Anatomy* (1864), p. 1.

earth's centre, is absolutely independent of the arrangement of the particles, and is equal to the sum of the weights of these particles. The volumes occupied by specified masses of homogeneous gases, on the other hand, are entirely dependent on the relative arrangement of the particles, and are not the sums of the volumes occupied by these particles when separated from each other. Most of the chemical properties of any homogeneous kinds of matter are not the sums of the properties of the particles of such kinds of matter.

Such then being, very broadly, the kind of properties considered in chemistry, we have next to inquire as to the meaning of the term composition. This inquiry at once carries us back to properties. Experiment shows that from certain kinds of homogeneous matter there can be obtained two or more different kinds of homogeneous matter, which new kinds of matter are wholly unlike the original in properties, and the mass of each of which is less than the mass of the original; the sum of the masses of the new kinds of matter being, however, always equal to the mass of the original matter. Experiment also shows that from certain kinds of homogeneous matter new kinds of matter can be obtained only by adding on to (or combining with) the original matter one or more different kinds of matter, and that in these cases the mass of the new kind (or kinds) of matter produced is greater than the mass of any one of the kinds of matter which have united to produce it, but is equal to the sum of the masses of all these kinds of matter. Experiment thus enables us to arrange all known kinds of homogeneous matter in two classes; those kinds belonging to the first class, *i.e.*, those from which can be obtained two or more different kinds each unlike, and weighing less than, the original, are called *compounds*; those belonging to the second class, *i.e.*, those which can be changed only by adding on to them some other kind of matter, are called *elements*. A compound may of course be changed by adding on to it a new kind of matter in the same way as an element may be changed; but an element can be changed in this way and in this way only. So far as exact knowledge goes, elements may be said to be completely homogeneous; not only are we unable to separate a specified mass of an element into particles unlike each other, by grinding, or cutting, or dividing the mass in any way, but we have every reason to suppose that the extremely minute particles of matter, by the union of which we are obliged to regard the mass as built up, are themselves completely identical in properties. Although by grinding, or cutting, or dividing by a machine, we cannot separate a specified mass of a compound into particles unlike each other, yet we are certain that the extremely minute particles of matter, by the union of which we are obliged to regard the mass as built up, are themselves built up of yet smaller particles, some of which are wholly unlike some others. But notwithstanding this distinction, which may perhaps be removed as more knowledge is gained, we are justified in applying the term homogeneous kind of matter to elements and compounds alike.

Chemistry then concerns itself with the con-

nexions between the properties and the composition of elements and compounds. By the composition of an element is meant, at present, simply a statement of the name of the element; the element is composed of itself. By the composition of a compound is meant, at present, a statement of the elements by the union of which the compound is produced, and of the mass of each element which goes to produce a specified mass of the compound. But the word composition, as we shall see hereafter, has a fuller meaning than this.

Let us then regard the composition and properties of compounds with the view of placing together those which are like and separating those which are unlike. The moment we attempt to do this, we find that our classification of compounds must include elements also. A series of compounds may be formed by the union of one element with other elements; the properties of these compounds present some points of similarity; the presence in all of them of the specified element is accompanied by certain more or less marked similarities of properties. We wish to connect properties of compounds with composition; therefore we must learn the properties of the elements which by their union produce these compounds; but this involves the study of these elements both as they are in themselves, that is, as they are when unacted on by other elements, and also as their properties are modified when the elements combine with others. We cannot then classify compounds without studying the properties of elements, and we cannot classify elements without studying the properties of compounds.

Compounds may be classified in accordance with (1) the number of elements in each; (2) the qualitative properties of the elements in each; (3) the quantity of the elements in each; (4) the quality and quantity of the elements in each; (5) the functions performed by each; (6) the qualitative and quantitative elementary composition and at the same time the function performed by each.

Making the number of elements in each compound the class-mark, we should have a division of compounds into binary, ternary, quaternary, &c.; but this arrangement would tell very little about the compounds in each class; many compounds may be binary compounds, and yet the differences between them be very great. If the qualitative properties of the elements in a number of compounds are made the class-mark, we should have a division into compounds of oxygen, compounds of chlorine, compounds of iron, and so on; but not only would this arrangement convey little information regarding the compounds classified, but it would involve an immense number of classes, and the classes would overlap each other; *e.g.* the chlorides of iron would be placed both in the class of chlorides and also in that of compounds of iron. Nor can the quantity of the elements in compounds by itself be made the characteristic mark of a class; else we should have vast numbers of quantitative analyses as the sole basis of classification. More hopeful is it to attempt a classification of compounds based on the functions which they perform under stated conditions; this scheme leads to the placing together *e.g.* of acids, basic

compounds, metallic compounds, peroxides, anhydrides, &c., &c.; but unless we connect the composition of the acids, the basic compounds, the anhydrides, &c., with the functions of each of these groups, our classification must at the best be one-sided and subject to continual modification. The characteristic mark of a class should be some property or circumstance, or a conjunction of properties or circumstances, which is easily detected, and which belongs to all the members of the class and to no others.

The property which we propose to employ as a class-mark is power of performing a stated action under stated conditions, and with this property we shall endeavour to connect a certain composition. The term composition must be interpreted as meaning not only a statement of the elements, and of the masses of these elements, which produce a specified mass of any given compound, but also a statement of the number of atoms of each element in the atomic complex or reacting chemical unit of the compound in question; or, in the case of gaseous compounds, of the number of elementary atoms in the molecule of the compound. We shall assume the molecular theory of the structure of matter, and the atomic theory of chemistry (*v. Atomic and Molecular Weights*, vol. i. p. 336). We shall also assume

evolution of carbon dioxide, and react with many metals to produce compounds composed of the metal and a portion of the elementary constituents of the acid, this action being frequently accompanied by evolution of hydrogen. Oxides which react in this way are generally speaking, but not always, oxides of non-metallic elements. Other oxides again exist which either do not dissolve in water, or dissolve only in relatively very large quantities of water, and which do not thus produce either alkalis or acids, but react with aqueous solutions of acids to form salts and water. Such oxides are for the most part oxides of well-marked metallic elements. Finally a few oxides exist which do not belong to any one of the three classes already considered; omitting these, the three classes of oxides may be named (1) alkali-forming or alkaline oxides; (2) acid-forming oxides or anhydrides; (3) salt-forming or basic oxides. The alkaline oxides are all oxides of metals, the acid-forming oxides are generally oxides of non-metals, and the salt-forming oxides are oxides of elements most of which are usually classed with the metals. The following list will serve as data on which a comparison of the properties with the composition of each of these classes of oxides may be based:

#### I. Alkali-forming oxides.

$\text{Li}_2\text{O}$ ,  $\text{Na}_2\text{O}$ ,  $\text{K}_2\text{O}$ ,  $\text{Rb}_2\text{O}$ ,  
 $\text{Cs}_2\text{O}$ ,  $\text{Tl}_2\text{O}$ ,  $\text{MgO}$ ,  $\text{CaO}$ ,  
 $\text{SrO}$ ,  $\text{BaO}$ ; ( $?\text{Ag}_2\text{O}$ ?  $\text{PbO}$ )

#### II. Acid-forming oxides.

$\text{B}_2\text{O}_3$ ;  $\text{CO}$ ,  $\text{CO}_2$ ;  $\text{N}_2\text{O}$ ,  $\text{N}_2\text{O}_3$ ,  $\text{N}_2\text{O}_5$ ,  
 $\text{N}_2\text{O}_4$ ;  $\text{SiO}_2$ ;  $\text{P}_2\text{O}_3$ ,  $\text{P}_2\text{O}_5$ ;  $\text{SO}_2$ ,  
 $\text{SO}_3$ ;  $\text{Cl}_2\text{O}$ ,  $\text{Cl}_2\text{O}_7$ ;  $\text{SeO}_2$ ;  $\text{TeO}_2$ ,  
 $\text{TeO}_3$ ;  $\text{I}_2\text{O}_5$ ; and the following  
oxides of metals, viz.  $\text{V}_2\text{O}_5$ ,  $\text{V}_2\text{O}_4$ ;  
 $\text{As}_2\text{O}_3$ ,  $\text{As}_2\text{O}_5$ ;  $\text{Sb}_2\text{O}_3$ ,  $\text{Sb}_2\text{O}_5$ ;  
 $\text{Nb}_2\text{O}_5$ ,  $\text{Ta}_2\text{O}_5$ ; ( $?\text{Bi}_2\text{O}_3$ ) ( $?\text{Pb}_2\text{O}_3$ )  
 $\text{CrO}_2$ ;  $\text{MoO}_3$ ;  $\text{WO}_3$ ;  $\text{Au}_2\text{O}_3$ ;  $\text{Ir}_2\text{O}_3$ ;  
 $\text{OsO}_3$ ;  $\text{PtO}$ ,  $\text{PtO}_2$ ;  $\text{PbO}_2$ ;  $\text{MnO}_2$ ;  
 $\text{SnO}$ ,  $\text{SnO}_2$ ;  $\text{TiO}_2$ ;  $\text{ZrO}_2$ .

#### III. Salt-forming oxides.

Most of the oxides not placed in groups I. and II.; the chief exceptions being  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{O}_2$ ,  $\text{NO}$ , and some of the oxides of  $\text{Cr}$ ,  $\text{Mo}$ ,  $\text{W}$ , and  $\text{U}$ . The oxides ( $\text{M}_2\text{O}$ ) of  $\text{Li}$ ,  $\text{Na}$ ,  $\text{K}$ ,  $\text{Rb}$ ,  $\text{Cs}$  and  $\text{Tl}$ , and the oxides ( $\text{MO}$ ) of  $\text{Mg}$ ,  $\text{Ca}$ ,  $\text{Sr}$ , and  $\text{Ba}$ , being already classed as alkali-forming, may be omitted from this group, although they react with acids to form salts; some metallic oxides containing relatively much oxygen, e.g.  $\text{Na}_2\text{O}_2$ ,  $\text{K}_2\text{O}_2$ ,  $\text{BaO}_2$ ,  $\text{Bi}_2\text{O}_3$ , &c., form salts by the action of acids but at the same time evolve oxygen.

that the reader is familiar with chemical formulae and notation.

A number of compounds exist which dissolve in water to produce more or less alkaline liquids, that is to say, liquids which exert a corroding action on organic fibres, change the tint of various vegetable colouring-matters, neutralise acids without evolution of any gas, precipitate the hydroxides of most heavy metals from solutions of salts of these metals, have a peculiar soap-like action on the skin, and saponify fats. The compounds which thus dissolve in water to produce alkaline liquids are found on analysis to be binary compounds of oxygen; the element present in combination with oxygen is in each case a metal. Other oxides exist which dissolve in water to produce more or less acidic liquids, or which can be obtained from acids, that is to say, compounds aqueous solutions of which, like alkalis, exert a corroding action on organic fibres and change the tint of various vegetable colouring-matters, which neutralise alkalis with the production of water and salts but without the evolution of any gas, neutralise carbonates of the alkali-metals with

The alkali-forming oxides are oxides of strongly marked positive elements; if more than one oxide of such an element exists, that with the less oxygen is alkali-forming. The acid-forming oxides are either oxides of the more negative elements (non-metals), or they are the higher oxides of the less positive metals; many of the anhydrides belonging to the latter class do not form acids when acted on by water, but are obtained by removing water (usually by the action of heat) from the hydrated oxides which are themselves feebly acidic in character. By a body of a feebly acidic character is meant a compound which, as a rule, is insoluble or nearly insoluble in water, does not react with aqueous solutions of alkalis to form salts, but gives rise to the production of salts when it is fused with an alkali; the salts thus produced are unstable and are easily separated into their constituent oxides. The salt-forming oxides which are neither alkaline nor acid-forming constitute by far the greater number of the well-marked metallic oxides. The physical properties of the oxides placed in the same class are not necessarily similar; thus  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{N}_2\text{O}$ ,  $\text{SO}_2$ , and

some other anhydrides, are gaseous under ordinary conditions of temperature and pressure, but the metallic oxides belonging to this class are solids, many of which melt, if at all, only at high temperatures.

The division of oxides into three classes, an outline of which has now been given, is based to a great extent on the properties of compounds which are produced by the interactions of these oxides with water on the one hand, and with acids on the other hand. In order then more completely to grasp the classification of oxides it is necessary to consider the properties and the classification of alkalis, acids, and salts.

The term *alkali* was originally applied to the ashes of sea-plants; but it was soon extended to include substances which, like the ash of seaweed, easily dissolved in water to form solutions having a soap-like action on the skin, affecting the colour of many vegetable matters, and reacting with acids with effervescence and the production of new substances wherein neither the properties of the alkali nor the acid were prominent. About the middle of the eighteenth century Black proved by quantitative experiments that the effervescence which occurs during the interaction of an acid and an alkali is caused by the outrush of a gas which existed in the alkali in combination with the other constituents of that body. That the same gas may also be obtained from the alkali by the action of heat was also proved by Black. From this time it became customary to distinguish mild or carbonated alkali from burnt or caustic alkali, the former being regarded as a combination of the caustic alkali with carbonic acid gas. Both carbonated and caustic alkali reacted with acids to produce the same substance, in which the properties of alkali and acid were lost, or rather merged into a new set of properties; the action was attended in the case of carbonated alkali with evolution of carbonic acid gas, but in the case of caustic alkali no gas was produced. Continued examination of alkali showed that the composition of the substance thus named was not always the same; this led to the recognition of more than one kind of matter exhibiting the characteristic properties of alkalis. Lavoisier adduced reasons for regarding the various alkalis as compounds of unknown metals with oxygen, but he did not succeed in actually demonstrating their composition. In 1807 Davy decomposed two alkalis, potash and soda, each into oxygen and a metal, by passing an electric current through them when moist, and a year later by the same agency he separated the three earthy bodies, lime, strontia, and baryta—bodies which to a great extent resemble alkalis in their properties—into oxygen, and in each case a metal. The composition of the various bodies having the properties already summarised as characteristic of alkali was now settled; these bodies were oxides of metals. But further investigation showed that aqueous solutions of these metallic oxides did not contain the oxides, but rather compounds of metal, oxygen, and hydrogen, and that these compounds, these hydroxides, were obtained as definite well-marked solid bodies by boiling off the water from the solutions in question. Now as the characteristic properties of alkali belonged to aqueous solutions of the metallic oxides under consideration it was better to

apply the name alkali to the hydroxides rather than to the oxides of certain metals. The composition of alkalis is represented by the formula  $\text{MOH}$ , where  $\text{M} = \text{Li}, \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ , or the compound radicle  $\text{NH}_4$ ; each of these compounds, except  $\text{NH}_4\text{OH}$ , is known as a definite solid body. An aqueous solution of ammonia,  $\text{NH}_3$ , reacts towards vegetable colouring-matters, towards acids, towards solutions of the salts of iron, copper, bismuth, tin, and many other heavy metals, in a manner very similar to that in which aqueous solutions of the five alkaline hydroxides,  $\text{MOH}$ , react towards these classes of substances. The salts formed by the action of acids on the hydroxides in question are generally isomorphous with, and in other properties similar to, the salts formed by the action of the same acids on an aqueous solution of ammonia. For these and a few other reasons the composition of an aqueous solution of ammonia,  $\text{NH}_3$ , is supposed to be similar to that of aqueous solutions of the solid alkalis; but the compositions of the latter solutions are represented by the symbols  $\text{LiOHAq}$ ,  $\text{NaOHAq}$ , &c., therefore the composition of the former solution is represented by the symbol  $\text{NH}_4\text{OHAq}$ . As we have hydroxides of the metals lithium, sodium, potassium, &c., so we have a hydroxide of the compound radicle ammonium ( $\text{NH}_4$ ); the former hydroxides are stable solid bodies, the latter exists only in aqueous solution (v. AMMONIUM COMPOUNDS, vol. i. p. 200). The hydroxides  $\text{MO}_2\text{H}_2$ , where  $\text{M} = \text{Mg}, \text{Ca}, \text{Sr}, \text{or Ba}$ , all more or less resemble the alkalis; these hydroxides are white solids, which require for solution much larger relative quantities of water than are needed to dissolve equal masses of the alkalis, but which thus produce solutions capable of neutralising acids without effervescence, of changing vegetable colouring-matter in the same way as solutions of the alkalis, of precipitating oxides or hydrated oxides of many heavy metals from solutions of the salts of these metals, of corroding organic fibres to some extent, of saponifying fats, and of quickly combining with carbonic acid to produce carbonates. As all the alkalis and the four compounds of  $\text{Mg}, \text{Ca}, \text{Sr}$ , and  $\text{Ba}$ , just mentioned are compounds each of oxygen, hydrogen, and a metal, and as many other metallic hydroxides, e.g.  $\text{CuO}_2\text{H}_2$ ,  $\text{Fe}_2\text{O}_2\text{H}_2$ , &c. &c., do not exhibit alkaline properties, it seems probable that the alkaline qualities of the hydroxides of  $\text{Li}, \text{Na}, \text{K}, \text{Rb}, \text{Cs}, \text{Mg}, \text{Ca}, \text{Sr}$ , and  $\text{Ba}$ , are to be associated with the properties of the metals,  $\text{Li}, \text{Na}, \text{K}, \dots \text{Ba}$ .

Thus in our attempts to classify oxides we are obliged to have regard, first, to the properties of alkalis, and then to the properties of the elements of which these alkalis are composed. What, then, are the properties of the metals  $\text{Li}, \text{Na}, \text{K}, \text{Rb}, \text{Cs}, \text{Mg}, \text{Ca}, \text{Sr}$ , and  $\text{Ba}$ ?

The metals  $\text{Li}, \text{Na}, \text{K}, \text{Rb}$ , and  $\text{Cs}$ , are silver-white solids, with low melting-points, and very small specific gravities ( $\text{Li}, \text{Na}$ , and  $\text{K}$ , being lighter than water); the metals are extremely easily oxidised, the process of oxidation being attended with production of much heat; they rapidly decompose cold water with evolution of half the hydrogen of the water decomposed and production of hydroxides  $\text{MOH}$  which remain in solution; during this process much heat is produced. The metals easily and rapidly combine

with the halogens and with sulphur; they are electro-positive to all other metals, and the most electro-positive metal of the group is that with the largest atomic weight (Cs). The compositions of the chief compounds of these metals are represented by the symbols  $M_2O$ ,  $MOH$ ,  $M_2S$ ,  $MSH$ ,  $MX$  ( $X = Cl, Br, I, F, CN$ ),  $M_2SO_4$ ,  $MHSO_4$ ,  $MNO_3$ ,  $MCO_3$ ,  $MHCO_3$ , &c., where  $M = Li, Na, K, Rb, \text{ or } Cs$ . These compounds are for the most part white and easily soluble in water; many of them are not chemically changed by the action of heat alone; all compounds of similar composition, e.g. all  $M_2SO_4$  or all  $MCl$ , are as a rule isomorphous; the sulphates  $M_2SO_4$  form alums by combination with sulphates of the composition  $M_2SO_4$ , where  $M = Fe, Al, Cr, In, \text{ or } Ga$ . The properties of the hydroxides  $MOH$  have already been detailed.

The metals  $Ca, Sr, \text{ and } Ba$  are whitish-yellow solids, the melting-points of which have not been accurately determined, but are somewhere about a red heat; the specific gravities of these metals are represented by small values, which are, however, decidedly greater than those that represent the specific gravities of the metals  $Li \dots Cs$ ; these metals are harder than the alkali metals, but, compared with the group of metals as a whole, they are soft; they quickly oxidise in air or oxygen, and decompose cold water with production of much heat, evolution of half the hydrogen of the water decomposed, and formation of solutions of the hydroxides  $MOH$ . In the cases of  $Li \dots Cs$  one atom of metal reacts with one molecule of water evolving one atom of hydrogen, in the cases of  $Ca \dots Ba$  one atom of metal reacts with two molecules of water evolving two atoms of hydrogen; the metals, so far as exact experiment goes, seem to combine easily and rapidly with the halogens and with sulphur; they are electro-negative to the metals  $Li \dots Cs$ , but positive to all other metals. The compositions of the chief compounds of these metals are represented by the symbols  $MO, MO_2H_2, MS, MS_2H_2, MX_2$  ( $X = Cl, Br, I, F, CN$ ),  $MSO_4, M_2NO_3, MCO_3$ , &c., where  $M = Ca, Sr, \text{ or } Ba$ . Most of these compounds are white; the oxides and hydroxides are not very soluble, the sulphates and carbonates are nearly insoluble, the chlorides and nitrates are easily soluble, in water; the hydroxides, nitrates, and carbonates are decomposed by the action of heat alone; almost all similar compounds are isomorphous; the sulphates do not form alums, nor do the compounds generally exhibit any marked tendency to form double or basic salts. The properties of the hydroxides have already been detailed.

The metal magnesium is a silver-white solid, the melting-point of which is about  $500^\circ\text{--}700^\circ$  (not accurately determined), and the specific gravity is a little greater than that of calcium; the metal is much more malleable and ductile than  $Li \dots Cs$  or  $Ca \dots Ba$ ; it is scarcely oxidised by exposure to air or oxygen at ordinary temperatures, but when rapid oxidation is begun by heating the metal in air or oxygen it proceeds with production of much heat and light. Magnesium decomposes water at  $100^\circ$  very slowly with formation of  $MgO_2H_2$ ; it does not act chemically on cold water; it does not combine with the halogens or with sulphur at ordinary tempera-

tures. The compositions of the chief compounds of this metal are represented by the symbols  $MgO, MgO_2H_2, MgS, MgX_2$  ( $X = Cl, Br, I, F, CN$ ),  $MgSO_4, Mg_2NO_3, MgCO_3$ , &c. Most of the compounds are white; the oxide and hydroxide are only very slightly soluble in water; the oxide combines with water to form  $MgO_2H_2$ , but much less heat is produced during this process than when  $CaO, SrO, \text{ or } BaO$ , combines with water to form the hydroxide. The hydroxide is easily decomposed by heat alone into oxide and water; the sulphate, nitrate, and halpid salts are easily soluble in water, the carbonate is nearly insoluble in water; many compounds of magnesium salts with those of the alkali metals, &c., are known; some of the magnesium compounds are isomorphous with the similar compounds of  $Ca, Sr, \text{ and } Ba$ , but the isomorphism of the two series of salts is very far from being complete. (For more details of the properties of the three classes of metals v. ALKALIS, METALS OF THE, vol. i. p. 114; ALKALINE EARTHS, METALS OF THE, vol. i. p. 112; and MAGNESIUM METALS.)

These facts concerning the metals whose hydroxides are the alkalis, and concerning those whose hydroxides more nearly approach the alkalis than do the hydroxides of any other elements, show that the property of forming an alkaline hydroxide is accompanied by the following properties on the part of an element: low specific gravity, not very high melting-point, small malleability and ductility, softness, occupation of a very positive position in the electrical series of elements, power of rapidly decomposing water with evolution of part of the hydrogen thereof, power of forming salts which are not easily decomposed by heat alone, and many of which are easily soluble in water, great readiness to combine with oxygen and with the halogens. Of all the metals whose properties we have considered in detail, magnesium differs most from the ideal alkali-forming metal; but the hydroxide of magnesium is decidedly less markedly alkaline than the hydroxide of any other metal in the two groups from  $Li$  to  $Sr$ .

When a given element exhibits a fair number of the properties given above as characteristic of the alkali-forming elements we may conclude that the hydroxide of that element will be more or less alkaline in its properties. There is a certain element characterised by the following properties: specific gravity large (11.9), melting-point moderately low ( $290^\circ$ ), very soft, malleability and ductility moderate, oxidises rather rapidly in air but action soon stops because of formation of film of oxide, burns rapidly in oxygen at about  $300^\circ$ , does not decompose water until a red-heat is reached; less positive than zinc, which is again less positive than  $Ca, Sr, \text{ or } Ba$ ; combines readily with the halogens and with sulphur; most of the salts of this metal are white and easily soluble in water, some of them are isomorphous with, and of similar composition to, salts of potassium. In many respects then this metal approaches the ideal alkali-forming element; but in others, notably its high specific gravity and comparatively negative position in the electrical series, it departs from the alkali-forming type. We should expect the oxide and hydroxide of this metal to present fairly close resemblances to the corre-

responding compounds of the lithium group of metals, but at the same time to show considerable differences from these compounds. As a matter of fact, the metal forms two oxides and two hydroxides; one pair of these compounds shows close analogies with the corresponding compounds of the alkali metals; the other pair shows fairly marked analogies with the corresponding compounds of aluminium. The metal in question, which is thallium, belongs to two groups of elements; it forms an alkaline oxide and hydroxide  $Tl_2O$  and  $TlOH$ ; and another oxide and hydroxide  $Tl_2O_3$  and  $TlO.OH$ .

Having thus learnt something regarding the properties and compositions of alkalis, let us turn to the second group of compounds which it is necessary to consider before we can complete the classification of oxides; let us briefly consider the group of *acids*. The name *oxygen* perpetuates the Lavoisierian conception of the composition of acids; this element was for Lavoisier emphatically the acid-producer. The products of the combustion in oxygen of sulphur, phosphorus, carbon, boron, nitrogen, selenium, and a few other elements, dissolve in water to form solutions which have 'acid reactions,' that is to say, have a sour taste, corrode organic fibres, change the tint of many vegetable colouring-matters, neutralise alkalis with production of salts and water, and dissolve many metals with evolution of gas (generally hydrogen). By removing water from these solutions, at least one definite compound can in most cases be obtained, composed of the element which had been burnt in oxygen, combined with oxygen and hydrogen; when this compound is again dissolved in water the original acid liquid is reproduced. Very many other compounds are known which form aqueous solutions characterised by acidic reactions as above enumerated; most of these compounds are composed of oxygen, hydrogen, and a third element. On the other hand, very many compounds formed by the union of oxygen, hydrogen, and a third element do not form acidic solutions when dissolved in water; and, finally, a few compounds are known, aqueous solutions of which are most definitely acidic, but which do not themselves contain oxygen. Oxygen is therefore not the sole acid-producing element; but the fact remains that by far the greater number of acids are composed of oxygen united with other elements.

Putting into one class all those compounds which dissolve in water with formation of solutions having acidic properties, as these have been already enumerated, and then tabulating the composition of these compounds, it becomes evident that they are all compounds of hydrogen with one or more other elements. Hydrogen then, rather than oxygen, would seem to be the acid-producing element. But further examination of the compounds of hydrogen shows that very many of these are not possessed of any of the characteristics of acids.

Is it possible then to trace any definite connexion between the composition of compounds and the possession or non-possession by them of acidic properties? In attempting to answer this question we are confronted with the great difficulty of chemical classification. We cannot define the class acids, just as we could not de-

fine the class alkalis: an ideal acid or alkali may be defined, but it is necessary to place in one or other of these classes many bodies which possess some of the properties of the ideal type, but in other properties diverge more or less widely from that type. Chemical classification, based on the notion of connecting properties with composition, is at best a typical classification, and such a system cannot be regarded as final in an exact science. The mark of a class should be some property or circumstance, or conjunction of these, which is clear and definite, and which belongs to all the members of the class and to no other bodies. But we cannot predicate any one property of acids which is perfectly clear and definite, and the possession or non-possession of which shall determine whether a specified compound is or is not to be admitted to this class. The reaction which occurs between an acid and a metallic hydroxide, or hydrated oxide, more nearly approaches to a good class characteristic than any other single property of acids. The products of the action in question are water and a compound formed of the metal of the hydroxide employed, and the elements of the acid excepting the whole or a part of the hydrogen; such a compound is called a *salt*. The following equations, representing the distribution of the elements of the reacting compounds before and after the mutual actions of various acids and metallic hydroxides, will illustrate, more clearly than can be done in words, the characteristic reaction of an acid:— (the symbol *Aq* is used to denote that the compound which it follows is dissolved in water)

1.  $HCl.Aq + NaOH.Aq = NaCl.Aq + H_2O.Aq$ .
2.  $HNO_3.Aq + TiOH.Aq = TiNO_3.Aq + H_2O.Aq$ .
3.  $H_2SO_4.Aq + KOH.Aq = KHSO_4.Aq + H_2O.Aq$ .
4.  $H_2SO_4.Aq + 2KOH.Aq = K_2SO_4.Aq + 2H_2O.Aq$ .
5.  $H_2SO_4.Aq + CuO.H_2 = CuSO_4.Aq + 2H_2O.Aq$ .
6.  $2H_2C_2O_4.Aq + PbO.H_2 = Pb(H_2C_2O_4)_2 + 2H_2O.Aq$ .
7.  $H_2C_2O_4.Aq + NaOH.Aq = NaH.C_2O_4.Aq + H_2O.Aq$ .
8.  $H_3PO_4.Aq + TiOH.Aq = TiH_2PO_4.Aq + H_2O.Aq$ .
9.  $2H_3PO_4.Aq + Fe_2O_3.H_2 = 2FePO_4 + 6H_2O.Aq$ .
10.  $H_2C_2O_4.Aq + CaO.H_2.Aq = CaC_2O_4 + 2H_2O.Aq$ .

An acid, then, may be provisionally defined as a compound of hydrogen with another element, or other elements, which, when dissolved in water, reacts with metallic hydroxides to produce water and a salt; a salt being a compound formed by the union of the elements of the acid, excepting the whole or a part of the hydrogen, with the metal of the metallic hydroxide. This definition is more commonly put into the shorter form, an acid is a compound containing *replaceable* hydrogen; but unless a definite meaning is given to the expression *replaceable* hydrogen, the definition of acid means nothing: the meaning of the words *replaceable* hydrogen is given in the longer definition of acid stated above. It is found that most compounds which are acids, in accordance with the provisional definition we have adopted, when dissolved in water form more or less corrosive liquids, which affect vegetable colouring matters, have a sour taste, and dissolve many metals with formation of salts and evolution of gas, which is usually hydrogen. But, on the other hand, some compounds which are possessed of many of the properties just detailed do not react with metallic hydroxides to form

salts; and, further, some compounds which are not possessed of any of the properties detailed do react with metallic hydroxides to form salts (*v. Acids*, vol. i. p. 47).

Looking at the composition of compounds which undoubtedly come under the definition of acid, and which at the same time are characterised by the other four properties enumerated, we find that the elements, or some of the elements, which by their union with hydrogen form the acid, are strongly negative in character; in other words, the element or elements other than hydrogen more or less resemble oxygen in their general chemical characteristics. As a whole, the elements which are classed as non-metallic are those which by union with hydrogen, and generally with hydrogen and oxygen, produce acids. When an acid is a compound of a metal united with hydrogen and another element or elements, for no binary metallic compound is acidic, that other element is always very negative. The following list exhibits most of the well-marked metallic acids which have been obtained in approximate purity:—

*Acids containing metals.*

$\text{H}_3\text{AsO}_4$	$\text{H}_2\text{SnO}_4$	$\text{H}_2\text{SnS}_4$
$\text{HAsO}_3$	—	—

The element which is generally combined with hydrogen and a metal in these acids is oxygen: in a few acids sulphur, in (?) three acids chlorine or bromine, and in a few acids the negative group CN is combined with hydrogen and a metal. It is also to be remarked that the metals which form well-marked acids by union with oxygen and hydrogen are those which, compared with the majority of the metals, are negative.

The general conclusion to be drawn from the facts now reviewed concerning the connexions between the properties and the composition of acids is, that those compounds which are decidedly acidic in properties, as the term acidic properties has been defined, are formed by the union of hydrogen with one or more decidedly negative elements. Acids are seen to be strongly contrasted with alkalis, both in properties and composition.

Oxides were divided (*v. p. 198*) into three groups; alkali-forming, acid-forming, and salt-forming, oxides. We can now understand in a general way what is meant by an alkali-forming oxide, or by an acid-forming oxide; it remains to consider the meaning of the term salt-forming as applied to oxides. At the outset, let us remark that a

salt-forming oxide may also be acid-forming, and that an alkali-forming oxide also is salt-forming. In considering the meaning of the term salt-forming oxide, it will therefore be necessary to study those typical compounds which possess the property in question to a marked extent. A salt has been already stated to be one of the products of the mutual action of an acid and a metallic hydroxide or hydrated oxide, and to be composed of the elements of the acid, excepting the whole or part of the hydrogen, united with the metal of the metallic hydroxide. It is impossible to generalise the properties of salts; many of them are soluble in water, some are insoluble; aqueous solutions of many exhibit acidic reactions, aqueous solutions of others exhibit alkaline reactions, and aqueous solutions of very many are neutral, i.e. exert no corroding action on organic fibres, have no sour or soap-like taste, do not affect vegetable colouring-matter, do not saponify fats, do not dissolve metals, or react with metallic hydroxides, &c. We must be content to look at the composition and the conditions of formation of salts. The composition of salts, regarding them as derivatives of acids, has already been stated. But salts are formed in other ways; they are sometimes produced by the mutual action of an acid-forming oxide and an oxide containing much oxygen, called a peroxide—e.g.  $\text{BaO}_2 + \text{SO}_2 = \text{BaSO}_4$ ; sometimes by the action of a salt-forming oxide on an aqueous solution of another oxide from which an acid has not actually been obtained, thus  $\text{K}_2\text{O} + \text{CO}_2\text{Aq} = \text{K}_2\text{CO}_3\text{Aq}$ ; sometimes by fusing together a metallic and a non-metallic oxide, e.g.  $\text{CaO} + \text{SiO}_2 = \text{CaSiO}_3$ ; sometimes by dissolving the sulphide of a less positive metal in a solution of the sulphide of a very positive metal, thus  $\text{As}_2\text{S}_3 + \text{K}_2\text{SAq} = 2\text{KAsS}_2\text{Aq}$ , or  $\text{WS}_3 + \text{K}_2\text{SAq} = \text{K}_2\text{WS}_2\text{Aq}$ ; and sometimes in other ways. The products of such actions as these are called salts, either because they can also be directly obtained by the mutual actions of acids and metallic hydroxides, or because they are composed of positive elements (metals) combined with negative elements, of which oxygen is usually one, and which negative elements are known to form acids by union with hydrogen, although the special acid of which any one of these specified salts is theoretically a metallic derivative may not have been prepared. All oxides are in a sense salt-forming; an alkaline oxide reacts with water to form an alkali, and the alkali reacts with an acid to form a salt; an anhydride reacts with water to form an acid, and by the mutual action of this acid and an alkali a salt is produced. But placing on either side those oxides which have been already classed as alkali-forming, and those which have been classed as acid-forming, there remain a great many oxides which are emphatically salt-forming oxides. As a class, these oxides form salts by reacting either with acids or with solution of oxides which act as if they contained acids, although no acid may actually be obtained when the dissolving water is removed, or, lastly, by reacting in the liquid state (not in solution) with the oxides of non-metals or of the more negative metals; examples of these three types of action are exhibited by the following processes:—

- (1)  $\text{CuO} + \text{H}_2\text{SO}_4\text{aq} = \text{CuSO}_4\text{aq} + \text{H}_2\text{Oaq}$ ,
- (2)  $\text{BaO} + \text{CO}_2\text{aq} = \text{BaCO}_3 + \text{Aq}$ ,
- (3)  $\text{K}_2\text{O} + \text{Ta}_2\text{O}_5(\text{fused}) = 2\text{KTaO}_3$ .

Some salt-forming oxides also produce salts, either by dissolving in concentrated solutions of alkalis, or by combining with alkalis when melted in contact with them; thus freshly ppt. aluminium oxide dissolves in solution of acids to form salts, and also in a concentrated aqueous solution of potash to form a salt; the two actions may be represented thus:

- (1)  $\text{Al}_2\text{O}_3 + 6\text{HClAq} = \text{Al}_2\text{Cl}_6\text{aq} + 3\text{H}_2\text{Oaq}$ ,
- (2)  $\text{Al}_2\text{O}_3 + 2\text{KOHaq} = \text{Al}_2\text{O}_3\text{K}_2\text{aq} + \text{H}_2\text{O}$ .

Again, moist  $\text{SnO}_2$  dissolves in concentrated aqueous potash to form a solution of potassium stannate  $\text{K}_2\text{SnO}_3$ , but the same oxide dissolves in hydrochloric acid to form stannic chloride,  $\text{SnCl}_4$ ; inasmuch as the acid  $\text{H}_2\text{SnO}_3$ , of which  $\text{SnO}_2$  is the anhydride, is known, we have in stannic oxide,  $\text{SnO}_2$ , an example of a compound which is at once an acid-forming and a salt-forming oxide. The oxide  $\text{MnO}_2$  dissolves in molten  $\text{KOH}$  to form the salt potassium manganate,  $\text{K}_2\text{MnO}_4$ ; the same oxide, when produced in a concentrated solution of lime, combines with the lime to form a series of salts, of which  $\text{CaMnO}_4$  may be taken as a representative; and, lastly, the same oxide, when hydrated, dissolves in strong sulphuric acid to form a sulphate of manganese  $\text{MnO}_2 \cdot 2\text{SO}_3$ . This oxide,  $\text{MnO}_2$ , thus exhibits some of the properties of two of the three classes into which we have divided oxides.

We began by proposing to arrange oxides in three classes in accordance with certain prominent reactions of these oxides; that we might attach to the reactions in question such definite meanings as should suffice for classificatory purposes, we were obliged to consider the meaning of the terms which summarise the reactions and composition of three other groups of compounds—acids, alkalis, and salts; that we might grasp the significance of these terms, we had to turn from compounds to elements, and roughly to classify these in accordance with their acid-forming or alkali-forming functions; but we found all this scheme of classification to be based at once on the composition and the functions of the bodies classified, and the word function we were obliged to interpret as implying the notion of mutual action and reaction between at least two kinds of matter. We arrived at no perfectly clear definition of any one of the classes of compounds under examination; we did succeed in conceiving the properties and the composition of a typical acid-forming, alkali-forming, and salt-forming oxide; but when we applied this conception, gained, it is to be remarked, from the study of actual acid-, alkali-, and salt-forming oxides, to individual compounds, we found that very few of these exhibited all the characteristics which we had laid down as marking off the typical acid-forming from the typical alkali-forming, or both from the typical salt-forming, oxide.

Looking back for a moment at the classification of oxides, and considering what it implies, one thing stands clearly out, namely, that this classification of oxides carries in itself a classification of elements. Those elements which form markedly alkaline oxides fall into one

class, those which form oxides which are distinctly anhydrides fall into a second class, and a third class includes those elements the best-marked oxides of which are neither alkali-forming nor acid-forming, but salt-forming. Or, putting the matter in even more general terms, the classification of oxides suggests a means of classifying the elements. Let us put into one class all the elements which, under similar conditions, form compounds similar in composition and function. Let us then examine the elements in a class with the view of finding whether they do or do not exhibit similarities in physical properties. If the result is fairly successful, let us examine more closely into the composition of the compounds belonging to specified classes, and endeavour to learn something of the structure of these compounds in the light which is thrown on structure by the molecular and atomic theory. Finally, let the knowledge which may thus be gained of structure react on that previously amassed concerning function, that by the help of both some advance may be made in finding a solution for the fundamental problem of chemistry, which is, to trace the connexions between changes of composition and changes of properties in homogeneous kinds of matter.

Instead of following the course of this investigation step by step, it will be more advantageous to begin with the leading principle, which has been gained after much laborious inquiry. In the article ATOMIC AND MOLECULAR WEIGHTS a sketch was given of the *periodic law*. The substance of that sketch it would be needless to repeat here; let us rather apply it to the point in hand, namely, the classification of the elements, remembering always that a good classification of elements implies and carries with it a good classification of compounds also.

The classification founded on the periodic law arranges the elements in *groups* and *series* (v. vol. I. p. 351); the members of the same group more or less closely resemble each other; the properties of the members of a series vary from member to member so that the last, that is the element with the largest atomic weight, is more unlike the first than any other member of the series. Each series to some extent repeats the characteristics of that which precedes it. The properties of an individual element are chiefly conditioned by (1) the group, (2) the series, to which it belongs, (3) its position in the group and in the series, (4) its relations to elements situated similarly to itself in other groups and series, and (5) the relations of the group and of the series to other groups and series. As regards the characteristics of individual groups and series, and the relations between various groups and series, it should be remarked, (1) that each group is made up of elements belonging to even series and elements belonging to odd series; (2) that an odd and an even series together comprise 14 elements, and that in the cases of series 4 and 5, 6 and 7, and 10 and 11, there is a group of three elements (Group VIII.) forming what is called by Mendeleeff a 'transition-period' from the even to the odd series; (3) that there is certainly no such 'transition-period' connecting series 2 and 3, but that very probably such a period of three elements will be discovered between series 8 and 9; (4) that the elements in

the even series, or in the odd series, of any group are more like one another than elements in the even are like those in the odd series; (5) that, omitting series 2 and 3, the passage from an even to an odd series is accomplished by a gradual change of properties, but the passage from an odd to an even series by a more sudden change of properties; (6) that the distinctly non-metallic elements occur in odd series, except in the case of series 2; (7) that, omitting series 2, easily gasified organo-metallic compounds, so far as data go at present, are formed only by elements which occur in odd series; (8) that the properties of hydrogen are so marked, and are typical of such diverse elements, that it is placed in a series [series 1] by itself; (9) that all the members of series 2 [Li to F], and at least the first member of series 3 [Na], are to a great extent marked by peculiar properties, and that the relations of these elements to those in series 4, and in the case of sodium to series 5, are rather markedly different from the normal relations of an odd series to the next odd series, or of an even series to the next even series. The elements Li to Na have been called by Mendeleeff 'typical elements.' The following table (copied with a few changes from one given by Mendeleeff) exhibits the arrangement of the elements in groups and in odd and even series (at. wts. in round numbers):—

		SERIES											
Groups	1	2	4	6	8	10	12						
I.	H=1	Li=7	K=39	Rb=85	Cs=133	—	—						
II.		Be=9	Ca=40	Sr=87	Ba=137	—	—						
III.		B=11	Sc=44	Yt=89	La=139	Yb=173	—						
IV.		C=12	Ti=48	Zr=90	Ce=140	—	—						
V.		N=14	V=51	Nb=94	Pr=144	Ta=181	—

VII.		Cl=35.5	Br=80	I=127	—	—	—						
	1	3	5	7	9	11	13						

As regards the mutual relations of groups and series, it should be further remarked that, calling the even series members of a group a family, and the odd series members a family, in groups 1 and 7 the family-character is more marked than the group-character, in groups 3, 4, and 5 the group-character preponderates over the family-character, and in groups 2 and 6 the two characters are about balanced, so that these two groups present, perhaps, the best examples for the detailed study of the application of the periodic law to the classification of elements. Group II. contains the following elements:—

Group II.				
Even series:	2	4	6	8
	Be=9	Ca=40	Sr=87	Ba=137
Odd series:	3	5	7	9
	Mg=24	Zn=65	Cd=112	Hg=200

The even series elements in this group are beryllium, calcium, strontium, and barium. The three metals, Ca, Sr, and Ba, are yellowish-white, rather soft, solids, with comparatively small specific gravities; their characteristic properties have already been detailed in the present article (v. p. 200). The metal beryllium differs considerably from the other even series members of the group; unlike these metals, it cannot be obtained by electrolysis of the chloride; the method by which beryllium is obtained is very similar to that whereby magnesium is prepared, viz. by heating the chloride with metallic sodium. Beryllium appears to be a silver-white, hard, solid; its specific gravity is small (approximately 1.7), melting-point high, not accurately determined, but certainly above 600°; the specific heat of this metal increases rapidly as temperature rises, and approaches a constant value between 400° and 500°. The spectrum of beryllium more nearly resembles that of lithium than of any other element, in the number, relative position, and intensity, of the lines; but the character of the lines of greatest intensity in the beryllium-spectrum closely resembles that of two pairs of lines in the spectrum of calcium. This metal does not oxidise in air at ordinary temperatures, and even when heated in oxygen it is only superficially oxidised; it combines with chlorine and iodine only at high temperatures; when heated with

sulphur, no sulphide of beryllium is formed; it very readily combines with silicon. Beryllium does not decompose water even at a red heat; it dissolves in an aqueous solution of potash with formation of beryllium oxide and evolution of hydrogen; it is easily soluble in dilute hydrochloric or sulphuric acid, but has little or no action on nitric acid. The compositions of the salts of beryllium are represented by the same formulae as express those of the salts of Ca, Sr, and Ba; the oxide BeO does not combine with water, but the hydroxide, Be(OH)<sub>2</sub>, can be prepared indirectly; this hydroxide is easily decomposed by heat alone, it resembles the hydroxides of zinc and of aluminium in being soluble both in acids and in aqueous potash, it combines with carbon dioxide to produce BeCO<sub>3</sub>; the oxide crystallises in the same (hexagonal) form as aluminium oxide; under certain conditions zinc oxide can also be obtained in this form; beryllium oxide usually occurs in combination with

lamina and silica, as beryl. Most of the salts of beryllium are white; the nitrate, sulphate, and chloride are soluble, the carbonate and phosphate are insoluble, in water. Beryllium sulphate does not form an alum, but does combine with potassium sulphate to form a double salt having the composition  $\text{BeSO}_4 \cdot \text{K}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$ : the chloride does not form double salts with the alkali chlorides; the carbonate is fairly stable towards heat, but easily forms basic, and also double, salts; the sulphate, which also readily produces basic salts, is completely decomposed into oxide and oxide of sulphur by the action of heat alone. The chloride and bromide of beryllium have been gasified; an ethide,  $\text{Be}(\text{C}_2\text{H}_5)_2$ , is known; it is a fuming liquid which takes fire when gently warmed in air.

The odd series members of the group we are considering are magnesium, zinc, cadmium, and mercury. The properties of the metal magnesium have already been stated in this article (v. p. 200); of the remaining metals, zinc and cadmium are very similar, while mercury differs in many respects from any other member of the group. Zinc and cadmium occur together in minerals, chiefly as sulphides; both are obtained by deoxidising the oxides by hot carbon; both are heavy, moderately hard, tin-white solids (S.G. Zn = 7.2, S.G. Cd = 8.6); both melt at fairly high temperatures (M.P. Zn =  $420^\circ$ , M.P. Cd =  $320^\circ$ ), and both can be volatilised at temperatures somewhat under  $1000^\circ$ . Cadmium is ductile and malleable, the ductility and malleability of zinc vary considerably with variations of temperature; both are easily soluble in the ordinary mineral acids, zinc dissolves in concentrated warm aqueous solutions of potash or soda, with evolution of hydrogen and production of an unstable zincate of the alkali metal ( $\text{zZnO}_2 \cdot \text{M}_2\text{O}$ ); both are nearly unacted on by air or oxygen at ordinary temperatures, but are rapidly burnt to oxides when heated in oxygen; both readily combine with the halogens and with sulphur. The formulæ which represent the compositions of the chief compounds of Be, Ca, Sr, Ba, and Mg, also represent those of the chief compounds of Zn and Cd; almost all similar salts of Zn and Cd are isomorphous. The oxides, MO, do not combine with water to form hydroxides; the hydroxides,  $\text{MO}_2\text{H}_2$ , are quite insoluble in water, and are readily decomposed by heat alone into oxides and water;  $\text{ZnO}_2\text{H}_2$  is soluble,  $\text{CdO}_2\text{H}_2$  is insoluble, in aqueous potash. The chloride, sulphate, and nitrate of either metal is soluble, the phosphate and carbonate are nearly, if not altogether, insoluble, in water; these salts show great readiness to form double salts, especially with the alkali metals and with ammonia, and also to form basic salts, but the zinc salts are more ready to undergo the latter changes than the salts of cadmium. Mercury differs from all other metals in being liquid at temperatures above  $-39^\circ$ . This metal occurs chiefly as sulphide, from which it may be obtained by heating with iron, and in other ways; it is a silver-white, heavy liquid (S.G. about 13.5); it boils at  $350^\circ$ , and is very easily volatilised; it is unacted on by oxygen until a temperature near  $350^\circ$  is reached, when it slowly combines with oxygen to form  $\text{HgO}$ . Mercury readily combines with the halogens and with

sulphur; it is without action on water; dilute nitric acid quickly dissolves mercury, and it is also soluble in hot concentrated sulphuric acid, but neither boiling hydrochloric, nor boiling dilute sulphuric, acid acts upon it. Mercury forms two series of salts, mercurous salts represented by  $\text{Hg}_2\text{O}$ ,  $\text{Hg}_2\text{Cl}_2$ ,  $\text{Hg}_2\text{SO}_4$ ,  $\text{Hg}_2\text{NO}_3$ , &c., and mercuric salts represented by  $\text{HgO}$ ,  $\text{HgCl}_2$ ,  $\text{HgSO}_4$ ,  $\text{Hg}_2\text{NO}_3$ , &c.; the latter, as a class, are more soluble in water, and are much more stable, than the former. No hydroxides of mercury are known;  $\text{HgO}$  is said to be very slightly soluble in water, and also in molten potash. The salts of mercury, especially the mercuric salts, form a great many double compounds, chiefly with the salts of the alkali metals; they also readily form many basic salts; a very large number of compounds of mercury salts with ammonia, and derivatives of ammonia, is known.

The following data present some of the measurements which have been made (chiefly by Thomsen) of the quantities of heat produced during similar changes undergone by the elements, or by compounds of the elements, in the group we are now considering:—<sup>1</sup>

M	[M.Cl <sup>2</sup> .Aq]	[M.Br <sup>2</sup> .Aq]	[M.I <sup>2</sup> .Aq]	[M.O.N <sup>2</sup> O <sup>2</sup> .Aq]	[M.O]
Ca	187,600	165,800	185,300	177,160	180,930
Sr	195,700	173,800	143,400	185,410	128,440
Ba	196,300	174,400	144,000	187,000	124,240
Mg	186,900	165,000	184,600	176,480	146,000
Zn	112,800	90,900	60,500	102,510	85,400
Cd	96,300	74,400	44,000	86,000	65,600
Hg	53,200 <sup>2</sup>	41,480 <sup>2</sup>	24,300 <sup>2</sup>	37,070	30,670
Hg <sub>2</sub>	62,600 <sup>2</sup>	50,950 <sup>2</sup>	28,400 <sup>2</sup>	47,990	42,200

M	[M.Cy <sup>2</sup> .5KCy.Aq]
Zn	62,230
Cd	44,750
Hg	27,780

So far as these data warrant us in drawing general conclusions, it appears that the quantity of heat produced during the occurrence of a similar chemical change increases as the atomic weight of the metal increases in the cases of even series members of Group II., but that the quantity of heat produced decreases as the atomic weight of the metals in odd series of the group increases. Further, it seems that the increase in the even series members is much less for equal increments of atomic weights than the decrease in the odd series members. And lastly it is seen that the value for magnesium, which is the first odd series member of the group, is generally nearly the same as the value for calcium, which is the first even series member for which thermal data have been observed. Unfortunately hardly any thermal measurements have yet been made for compounds of beryllium; the follow-

<sup>1</sup> The square bracket denotes that the thermal value of the chemical change which occurs between the bodies within the brackets is measured; the comma means that chemical action occurs between the bodies the symbols of which are separated by this comma; the symbols of elements and compounds are to be read in grams; the figures represent gram-units of heat produced; the symbol Aq is used to denote so large a mass of water that an increase in this mass would not affect the thermal value of the change. Thus  $[\text{Ca.Cl}_2\text{.Aq}] = 187,600$  means that 187,600 gram-units of heat are produced when 40 grams of calcium and 71 grams of chlorine combine, in presence of much water, to produce 111 grams of calcium chloride.

<sup>2</sup> These figures represent the heats of formation of solid  $\text{HgCl}_2$ ,  $\text{Hg}_2\text{Cl}_2$ ,  $\text{HgBr}_2$ ,  $\text{HgI}_2$ , and  $\text{Hg}_2\text{I}_2$ , respectively.

ing numbers, taken from Thomsen's work, show that the heat of neutralisation of beryllium hydroxide is very much less than that of the other even series members of the group, or of magnesium, and approaches the values for zinc, cadmium, and mercury:—

Q	[Q.2HClAq]
BeO.H <sub>2</sub>	16,100
CaO.H <sub>2</sub>	27,900
SrO.H <sub>2</sub>	27,630
BaO.H <sub>2</sub>	27,780
MgO.H <sub>2</sub>	27,690
ZnO.H <sub>2</sub>	19,880
CdO.H <sub>2</sub>	20,290
HgO	18,920

Looking at these thermal measurements as a whole it is clear that, thermally considered, magnesium is very analogous to the three metals Ca, Sr, and Ba; that the three metals Zn, Cd, and Hg form a second class, marked off from the Mg...Ba class; and that, if one may draw any conclusions from the meagre data, beryllium seems to belong to the zinc rather than to the magnesium class. A consideration of the thermal values of the reactions of the metals in Group II. with acids shows that mercury is more widely separated from the other members of the group than these other members are from one another. Thus, take the values of the differences (1) between the heats of formation of the chlorides of the metals and that of gaseous hydrochloric acid, and (2) between the heats of formation of aqueous solutions of the nitrates of the metals and that of aqueous nitric acid; these differences give comparative representations of the quantities of heat produced, or which disappear, when equivalent masses of the metals react (1) with the same (equivalent) mass of gaseous hydrochloric acid, and (2) with the same (equivalent) mass of nitric acid dissolved in much water:—

M	[M.Cl <sup>1/2</sup> ]-[H <sup>1/2</sup> .Cl <sup>1/2</sup> ]	M	[M.O.N <sup>1/2</sup> O <sup>1/2</sup> Aq]-[N <sup>1/2</sup> O <sup>1/2</sup> .Aq]
Ca	125,820	Ca	117,520
Sr	140,550	Sr	125,770
Ba	150,740	Ba	127,380
Mg	107,010	Mg	116,840
Zn	53,210	Zn	42,870
Cd	49,240	Cd	26,360
Hg <sub>2</sub>	18,600	Hg <sub>2</sub>	-11,650 (used)
Hg	9,200	Hg	-22,570 (used)

As a general rule, such thermal data as are given here and elsewhere in this article represent differences between the quantities of energy degraded from more chemically available to less chemically available forms, during similar reactions. Of two systems producible from the same initial system, that one will be the more stable the production of which is attended with the running down of the greater quantity of energy. It is most important to trace connections between the compositions of chemical systems and the quantities of energy degraded during the production of these systems; but such thermal data as are given here can only be regarded as affording bases for very rough comparisons of the stabilities of the various systems produced by the different chemical operations formulated (v. further EQUILIBRIUM, CHEMICAL; and PHYSICAL METHODS).

Further data on which comparisons of the

compounds of the elements in Group II. may be based are furnished by (1) the melting-points, and (2) the so-called specific volumes, of similar compounds. The specific volume of a compound is defined as the quotient obtained by dividing the formula-weight by the specific gravity of the solid compound; it represents the volume, in cubic centimetres, occupied by the mass of the solid compound, in grams, represented by the formula of the compound. The difference between the specific volume of a binary compound and that of one of the elements contained in one formula-weight of the compound may be taken as representing the specific volume of the other element in one formula-weight of the compound; these differences afford useful data for comparing similar compounds of elements in the same or different groups:—

Melting-points of chlorides and bromides (approx.).

BeCl <sub>2</sub>	600°	BeBr <sub>2</sub>	600°
CaCl <sub>2</sub>	720	CaBr <sub>2</sub>	680
SrCl <sub>2</sub>	825	SrBr <sub>2</sub>	630
BaCl <sub>2</sub>	800	BaBr <sub>2</sub>	810
MgCl <sub>2</sub>	700	MgBr <sub>2</sub>	700
ZnCl <sub>2</sub>	260	ZnBr <sub>2</sub>	400
CdCl <sub>2</sub>	540	CdBr <sub>2</sub>	570

As regards the melting-points of chlorides and bromides, we see that the five metals Be, Ca, Sr, Ba, and Mg, are closely related to each other, while the three remaining metals of the group, viz. Zn, Cd, and Hg, form a class by themselves. As regards the specific volumes of oxides, we notice that the values increase from BeO to BaO, then fall to MgO, and again increase from MgO to HgO; the great difference between the value for CaO and that for BeO (10), and the smaller difference between the value for BeO and MgO (4), suggest that BeO is more allied to the group MgO . . . . HgO than to the group CaO, SrO, BaO. An analogy between BeO and the oxides of Zn, Cd, and Hg, is also pointed to by the value for the specific volume of O in the oxides MO.

Finally, let us tabulate the differences between the values of the atomic weights of pairs of consecutive metals in the group we are considering:—

Even series	Ca - Ba	} = 31	Sr - Ca	} = 47
	40 - 9		87 - 40	
	Ba - Sr		50 + 47	
	137 - 87	= 50;	$\frac{50 + 47}{2}$	= 48.5.
Odd series	Zn - Mg	} = 41	Cd - Zn	} = 47
	65 - 24		112 - 65	
	Hg - Cd		$44 + 47 + \frac{41}{3}$	
	200 - 112	= 88 = 44 × 2;	$\frac{44 + 47 + 41}{3}$	= 44.
	47 + 50 + 41 + 47 + 44 = 458.			
	5			

Omitting the difference Ca - Be, it is seen that the difference between the atomic weights of a pair of consecutive elements approaches the value 45; and that the difference is rather larger in the cases of the elements belonging to even series than in those of elements belonging to odd series. But the difference Ca - Be is only 31; in this respect beryllium stands marked off from the other elements of the group. If the differences between the values of the atomic weights of the first and second even series members of Groups I. to VII. are tabulated, it is found that this difference varies from 32 (K - Li) to 36 (Mn - F), and has a mean value of 34; but 34 is considerably less than 45, which is about the mean difference between any two elements (omitting the elements from Li to Na) in the same group and in consecutive even, or consecutive odd, series.

Looking back at the properties of the elements in Group II., it appears that beryllium is distinctly marked off from the other elements of the group; that calcium, strontium, and barium are more closely related to each other than they are related to any other elements of the group; that the relations between zinc and cadmium are most marked; and that mercury is to some extent separated from the other members of the group. Beryllium approaches magnesium in the method of its preparation; in its high melting-point; in the unreadiness with which it oxidises; in the ease with which its hydroxide is decomposed by heat; in the solubility of its sulphate; in the specific volume of its oxide; and in some other properties. Beryllium approaches calcium, among other respects, in the nature of its spectrum; and in the readiness with which its hydroxide combines with carbon dioxide. In the melting-point of its chloride and bromide, beryllium approaches the three metals calcium, strontium, and barium. The analogies between beryllium and zinc are marked by the following among other properties: action on water; solubility in aqueous potash; crystalline form of the oxides. The solubility of beryllium sulphate in water; the readiness with which basic salts, and also double salts, of beryllium are produced; the existence of gasifiable chloride, bromide, ethide, and propide, of beryllium; the specific volume of oxygen in beryllium oxide; and the thermal value of the neutralisation, by aqueous hydrochloric acid, of beryllium hydroxide; these properties indicate the analogy between beryllium and the three odd series members of the group, zinc, cadmium, and mercury. Calcium, strontium, and barium certainly stand by themselves; but in the specific volume of the oxygen in its oxide, and more especially in the thermal values of similar reactions, the odd series metal magnesium is closely related to these three even series metals. Mercury is marked off from the

other elements of the group by the fact that it forms two series of salts, and by the thermal values of the reactions between it and hydrochloric and nitric acids; but in the general character of its persalts, in the melting-points of its chloride and bromide, in the specific volume of its oxide and of the oxygen therein, mercury is clearly related to zinc and cadmium; and in the solubility of its oxide in molten potash, the relationship of mercury more especially to zinc and beryllium is rendered evident. An element has yet to be discovered which shall have an atomic weight equal to about 158, and which shall form a link between cadmium and zinc on one side and mercury on the other.

Putting together all we have learned of the elements and the compounds of the elements in Group II., we see that the group contains certain sub-groups or families, but that the special characteristics of these families are balanced by the strength of the group-character which impresses itself on all the members of the group.

Group VI. comprises the following elements:—

Even series		8		10		12	
2	4	6	8	10	12	14	16
O = 16	Cr = 52	Mo = 96	—	W = 184	U = 240		
Odd series		7		9		11	
3	5	7	9	11	13	15	17
S = 32	Se = 79	Te = 125	—				

We have here two families: the even series members O, Cr, Mo, W, and U; and the odd series members S, Se, and Te. But in many respects the first member of the even series family, oxygen, more resembles the odd series family than it resembles the other members of its own family. There is a distinct line of separation between oxygen on one side and Cr, Mo, W, and U on the other side. The four members of the even series family Cr . . . U may be divided into two sub-families, Cr and Mo, and W and U; but there are well-marked analogies between Cr and U on the one hand, and between Mo and W on the other hand. Finally, some of the members of the even series family, besides oxygen, show very distinct relations to members of the odd series family; e.g. Cr and S, and U and Te, are more or less closely related.

Let us consider these relationships very briefly. The compositions of the binary compounds of O, S, Se, and Te, emphasise the relations between the four elements: we have  $MH_2$ ,  $MCl_2$ ,  $MK_2$ ,  $MCa$ ,  $M(C_2H_{2n+1})_2$ , &c., where M = O, S, Se, or Te. The properties of these compounds are also very similar. No hydrides of the other even series members (Cr . . . U) are known, the best-marked chlorides of these elements are not  $MCl_2$ , nor do these elements form compounds with K, Ca, or the radicles  $C_2H_{2n+1}$ . There is a less-marked gap between the physical properties of O on one hand, and S, Se, and Te on the other, than between the former element and Cr, Mo, W, and U: thus, the melting-points of S, Se, and Te all lie under 550°, whereas Cr, Mo, and W, are scarcely fusible at the highest attainable temperatures, and U melts only at a full red heat. The specific gravities also of S and Se are less than 5, whereas the values of this quantity for Cr . . . U vary from 6.7 (Cr) to 19 (W). The specific gravity of Te is about

6-2. The elements S, Se, and Te, are distinctly non-metallic and negative; their oxides are acid-forming; these elements do not replace the hydrogen of acids with formation of salts; in these respects they approach closely to oxygen, which is the typical non-metallic acid-forming element. Tellurium, however, is to some extent separated from selenium and sulphur; it is a white, brittle solid; its haloid compounds are much more stable than those of S or Se; its oxides are not strongly acid-forming; the acids  $H_2TeO_3$  and  $H_2TeO_4$  are easily separated into water and anhydride, they are only slightly soluble in water, and are feeble acids (this statement may be made although the *relative affinities* of these acids have not yet been determined). Thomsen's measurements of the relative affinities of sulphuric and selenic acids ( $H_2SO_4$  and  $H_2SeO_4$ ), and the confirmation of these results by Ostwald's study of the electrical conductivities of aqueous solutions of these acids with varying masses of water (v. ARFENR, vol. i. pp. 75, 81, 83), show that these two acids are most closely related in their powers of combining with bases. The heat of formation of aqueous solutions of the oxides  $MO_3$ , however, point to a closer relation between Se and Te on one hand, than between either of these elements and S on the other hand: thus,

$$[M, O^*, Aq] = \begin{cases} 142,410 & \text{when } M = S \\ 76,660 & \text{,, } M = Se \\ 98,380 & \text{,, } M = Te. \end{cases}$$

Notwithstanding these resemblances we must admit that oxygen is distinctly cut off from the other members of the group, whether they be even series, or odd series, elements. Thus the thermal values of the formation of hydrides reveal a great gap between O and S:  $[H^*, O] = 68,360$ , but  $[H^*, S] = 4,740$  (unfortunately values for  $[H^*, Se]$  and  $[H^*, Te]$  have not yet been determined). Oxygen, like beryllium in Group II., is a so-called 'typical' element; the relations of this element to the odd series family of its group—S, Se, and Te—are not unlike the relations of the typical Be to the members of its group which belong to odd series—Mg, Zn, Cd. Oxygen is distinctly cut off from the even family Cr . . . U by its physical properties; by the composition of compounds with the same elements, e.g.  $OCl_2$ ,  $O_2Cl$ ,  $CrCl_3$ ,  $MOCl_3$ ,  $WCl_3$ ,  $UCl_3$ ; by the properties of many of these compounds, e.g.  $OCl_2$  boils at  $-18^\circ$ ,  $MOCl_3$  and  $WCl_3$  melt between  $200^\circ$  and  $300^\circ$ , the heat of formation of  $OCl_2$  has a large negative value, the heats of formation of chlorides of the other elements have not been determined, but from established analogies there can be no doubt that the numbers representing these heats of formation have large positive values; further the elements Cr, Mo, W, U, act both as acid-forming and salt-forming elements, whereas oxygen is in the most marked way the typical acid-forming element.

The even family Cr . . . U may be broadly divided into two sub-families, Cr and Mo, and W and U. Thus the specific gravities of Cr and Mo are, respectively, 6.7 and 8.5, of W and U 19 and 18.5; the specific volumes (i.e. atomic weight  $\div$  S.G. of solid) are 7.7 and 11.3, and 9.7 and 12.9. Some of the oxides of chromium, e.g.  $Cr_2O_3$ , are distinctly salt-forming, but  $CrO_3$  is the anhydride of a well-marked acid,  $H_2CrO_4$ , from which is derived a large series of well-marked

salts, for the most part isomorphous with similar sulphates and manganates. The oxides of Mo can scarcely be classed as salt-forming, although  $MoO_3$  is said to dissolve in acids without evolution of oxygen;  $MoO_3$  is the anhydride of an acid  $H_2MoO_4$ ; two classes of chromium salts exist, chromous salts represented by  $CrSO_4 \cdot 7H_2O$ , and the more stable chromic salts represented by  $Cr_2(SO_4)_3$ ,  $Cr_2(NO_3)_6$ , &c.; hydrated oxides of the composition  $MOxH_2O$ , both of Cr and Mo, seem to exist, but they are easily oxidised to compounds of the form  $M_2O_x \cdot xH_2O$ . The relations of W to U are similar to those of Mo to Cr; few, if any, distinct salts are known obtained by the replacement of the hydrogen of acids by W, but U forms two well-marked series of salts, represented by  $USO_4$  and  $UO_2SO_4$ , respectively; the oxides  $WO_3$  and  $UO_3$  are both anhydrides of acids  $H_2W(U)O_4$ . The oxide  $WO_3$  resembles  $MoO_3$  in that it dissolves in acids without evolution of oxygen;  $WO_3$  and  $MoO_3$  also form double compounds with various anhydrides, e.g. with  $P_2O_5$ ,  $SO_3$ , &c. The salt-forming character of the oxides of the family Cr, Mo, W, U, decreases from Cr to Mo, and again increases from W to U, but at the same time the extremes of the family (Cr and U) produce more distinctly marked acid-forming oxides ( $MO_3$ ) than either of the means (Mo and W). Finally, the highest members of the odd and even series of Group VI., Te and U, are, on the whole, more positive (although U produces a well-marked acid-forming oxide) than the other members of either family; and the first member of the even family, viz. Cr (excepting oxygen, which belongs both to the odd and the even families), shows fairly marked analogies with the first member of the odd family, viz. S.

Summing up the characteristics of Group VI., and comparing them with those of Group II., we see that the former group, as a whole, is non-metallic; its members are comparatively negative, and their best-marked oxides, as a class, are acid-forming; and we find in it two families, one of which, Cr . . . U, is more metallic and salt-forming, and the other, S . . . Te, is more non-metallic and acid-forming. Similarly we find in Group II. two families, one more distinctly metallic than the other; but, on the other hand, the whole character of Group II. is metallic, and the oxides of the members of the group are salt-forming. In each group we have found a 'typical' element: in Group VI. oxygen, in Group II. beryllium; the properties of this element to some extent summarise the properties of all the members of the group. The difference between the value of the atomic weight of oxygen and that of the next even series member of Group VI., viz. Cr, is 36; the difference between the atomic weight of beryllium and that of the next even series member of Group II., viz. Ca, is 31; the mean difference between any two consecutive even or odd members of either group is about 45; oxygen perhaps rather more closely approaches the properties of the odd family of its group than beryllium approaches the properties of the family of Group II. the members of which belong to odd series.

Let us now turn for a moment to those groups in which the family-character preponderates over the group-character, Groups I. and VII., and to

those in which the group-character is much more marked than the family-character, Groups III., IV., and V.

## Group I.

Even Series—

2 4 6 8  
Li=7 K=39 Rb=85 Cs=133

Odd Series—

3 5 7 9 11  
Na=23 Cu=63 Ag=108 — Au=197

The very marked similarity between Li, Na, K, Rb, and Cs, both as regards the metals themselves and their compounds, quite overshadows the much more feebly marked similarities which exist between Cu, Ag, and Au. But the thermal values of the reactions between lithium and water, between Li and O, Li and Cl, or Li and Br in presence of water, &c., the comparative insolubility of LiOH, Li<sub>2</sub>CO<sub>3</sub>, Li<sub>3</sub>PO<sub>4</sub>, the non-formation of an alum containing Li, the non-formation of double salts containing LiCl, the comparatively less ready oxidation of Li, and some other properties, show that lithium is to some extent separated from the metals Na . . . Cs. The properties of those salts of copper of which the chloride Cu<sub>2</sub>Cl<sub>2</sub> is a representative, exhibit some analogies with those of the compounds of lithium. Silver approaches the even family of Group I. in the composition of all its well-marked salts, in the distinct alkalinity of its oxide, and in the fact that silver sulphate forms an alum. Although gold is distinctly marked off from the other members of the group, yet in the softness of the metal, in the facts that compounds of the form M<sub>2</sub>O are known, that the auric haloid compounds very easily form double salts with the haloid compounds of Na . . . Cs, that Au<sub>2</sub>O and Au<sub>2</sub>S are sol. in water, and in a few other respects, this metal exhibits some analogies with the even family of the group and with sodium.

## Group VII.

Even Series—

2 4  
F=19 Mn=55

Odd Series—

3 5 7  
Cl=35.5 Br=80 I=127

Here the family-character of the odd series members impresses itself on the whole group; fluorine exhibits definite relations to the odd family, but the two facts that it forms no compounds with oxygen, and that its compounds with hydrogen and the alkali metals exhibit the greatest readiness to form double salts, suffice to cut it off to some extent from Cl, Br, and I. The heat of neutralisation of HF is considerably larger than the heat of neutralisation of HCl or HBr; [HMAq, NaOHAg]=13,740 when M=Cl or Br, but =16,250 when M=F, but the *relative affinity* of HF is very small; it is approximately equal to 5 when that of HCl=100, and that of HBr=95 or so. The thermal values of some similar reactions of Cl, Br, and I, show that these elements are not so closely related to each other as a consideration of the outstanding chemical properties of their compounds would lead one to suppose; thus, [H, Cl]=22,000; [H, Br]=8,040; [H, I]= -6,040 (absorbed). The

Vol. II.

differences between the properties of perchloric and periodic acids also emphasise the differences between chlorine and iodine. The isomorphism of permanganates and perchlorates, the markedly acid-forming character of MnO<sub>2</sub>, and the existence of permanganic acid, establish a connection, feeble though it be, between manganese and the other members of Group VII. In studying the relations of the members of this group it should not be forgotten that no representative of series 6, 8, 9, 10, 11, 12 or 13, is at present known.

## Group III.

Even Series—

2 4 6 8 10  
B=11 Sc=44 Y=89 La=139 Yb=173

Odd Series—

3 5 7 9 11  
Al=27 Ga=69 In=114 — Tl=204

The group-character is here impressed on all the elements; Al and Ga form a family to which In is allied, and Tl shows analogies in one class of compounds; Sc is not without analogies to Al and Ga, it is also distinctly related to B; of the other metals too little is known to enable us clearly to see their analogies. The last member of the group, thallium, astonishes us by the marked way in which in the thallous salts (Tl<sub>2</sub>O, Tl<sub>2</sub>SO<sub>4</sub>, &c.) it approaches the even series members of Group I., viz. Li . . . Cs. The typical element, boron, while showing analogies with all the other members of the group, and with other elements, e.g. with C and Si, is yet different from any of them; it is a good representative of the want of family likeness between the even series members or the odd series members of this group, and at the same time of the distinctly group character which is impressed on all the elements in the group.

## Group IV.

Even Series—

2 4 6 8 10 12  
C=12 Ti=28 Zr=90 Ce=140 — Th=232

Odd Series—

3 5 7 9 11  
Si=28 Ge=72 Sn=118 — Pb=207

Here again the even series members do not form a family marked off from the odd series members. Certain minor families are, it is true, to be found in the group, but on the whole the group-character much preponderates. Carbon stands by itself; it is marked off from all other elements by the immense number and complexity of the compounds which it forms with H, O, N, S, and the halogens. Most nearly related to carbon we have the first odd series member of the group, silicon; the silico-organic compounds, the existence of allotropic varieties of silicon, the relations between the specific heat of silicon and temperature, the thermal values of similar reactions of carbon and silicon, exhibit the analogy between these elements (*v. CARBON GROUP OF ELEMENTS*). The physical properties of Ti and Zr, the stability, and acid-forming character, of their oxides MO<sub>2</sub>, the volatility of their chlorides MCl<sub>4</sub>, the isomorphism of some titanates and zirconates with silicates, these points emphasise the connections

P

between Ti, Zr, Si, and C. But the formation of the sulphate  $Ti(SO_4)_2$ , of various salts of zirconium, *e.g.*  $Zr(SO_4)_2$ ,  $Zr(NO_3)_4$ , &c., show that these elements incline also towards Ce and Th which follow them in the even series, and towards Sn and Pb which belong to odd series of the same group. Cerium forms salts analogous to those of zirconium, *e.g.*  $Ce(SO_4)_2$ , but its most marked compounds are represented by the peroxide  $CeO_2$ . Thorium again approaches more closely to Ti and Zr than Ce does; the existence of  $ThO_2$ ,  $Th(SO_4)_2$ ,  $K_2ThF_6$ ,  $ThF_4$ , marks this analogy. Tin and lead resemble each other physically more than they resemble other members of the group; they exhibit the group-character in their oxides  $MO$  and  $MO_2$ , in their chlorides (or ethides)  $MCl_2$ , in their salts  $K_2MO_4$ ; tin further exhibits this character in its stannic salts  $Sn(SO_4)_2$ ,  $Sn(NO_3)_4$ , &c.; but each of these elements produces compounds which have no analogies among those of the other members of the group.

## Group V.

## Even Series—

2 4 6 8 10  
N = 14 V = 51 Nb = 94 Di = 144 Ta = 182

## Odd Series—

3 5 7 9 11  
P = 31 As = 75 Sb = 120 Er = 166 Bi = 208

The group-character is so impressed upon the whole of these elements that we may almost say there are no families; and yet the group falls into two subdivisions, each of which nearly repeats the characteristics of the other. From N to Ta we pass from a most markedly non-metallic, acid-forming, element to an element which, on the whole, is more metallic than non-metallic; from P to Bi we repeat the same gradation, only here the starting-point is an element rather less negative in its functions than nitrogen, and the last member of the series is decidedly more positive than tantalum. The less prominently acid-forming character of phosphorus as compared with that of nitrogen is exhibited, among other ways, by the *relative affinities* of nitric and phosphoric acids; the former being taken as 100, the latter is approximately equal to 20. The balance of metallic and non-metallic properties in tantalum is well shown by the action of acids on aqueous solutions of potassium tantalate. Acids whose relative affinity is large, *e.g.* sulphuric or hydrochloric acids (affinity = (approx.) 70 and 100), decompose this salt and pp. tantalic acid ( $H_2TaO_5$ ) in combination with a portion of the acid used; acids with a smaller affinity, *e.g.* sulphurous acid (affinity not determined, but, from Ostwald's electrical experiments, it must be considerably less than  $H_2SO_4$ ), completely pp. pure tantalic acid; acids with yet smaller affinities, *e.g.*  $H_3PO_4$  (affinity about 20), pp. potassium tantalate; and, lastly, acids with very small affinities, *e.g.* acetic or succinic acid (affinities 6 and 7 respectively), cause no pp. when added to solutions of potassium tantalate. That the last member of the odd series family, viz. bismuth, is more metallic than the last member of the even series family, viz. tantalum, is shown by the fact that in all its well-established

compounds bismuth is positive to the other elements with which it is combined, and that if hydrated bismuthic oxide,  $Bi_2O_3 \cdot 5H_2O$ , acts as an acid it forms salts which can scarcely be obtained in definite form, and which are certainly at least partly decomposed by the action of hot water.

We have thus endeavoured to draw the outlines of a scheme of classification of the elements and their compounds based on the comparison of those which are similar in physical and chemical properties, and by similar chemical properties we have implied similarity of function and similarity of composition. It yet remains, however, to examine somewhat more closely into the composition of the compounds classified, with the view of finding whether anything can be learnt of the structure of these bodies in the sense which is given to the word structure by the molecular and atomic theory. The compositions of the highest oxides, and of some of the other compounds of the elements, appear to vary periodically with variations in the atomic weights of the elements. If R represent the mass of an element expressed by its atomic weight, and if X represent the masses of F, Cl, Br, or I, expressed by the respective atomic weights of these elements, or the masses of the groups OH, NO, ClO, &c., expressed by these formulae, or the masses of the elements or groups of elements expressed by halves of the formulae O, S, SO, CrO, &c., then we may say that the compositions of the oxides

$R_2O, RO, R_2O_2, RO_2, R_2O_3,$

are expressed by the symbols

$RX, RX_2, RX_3, RX_4, RX_5,$

We may also say that the compositions of the salts

$R_2SO_4; R(NO_3)_2; R(NO_3)_3, ROCl, R_2(SO_4)_3,$   
 $RONO_2; ROCl_2,$

are expressed by the symbols

$RX; RX_2; RX_3, RX_4, RX_5, RX_6; RX_7,$

In this way it becomes possible to give general expressions for the forms of the highest stable oxides characteristic of each group, and also for the forms of the highest well-marked salts of the elements of each group. It is generally found that the greater the value of X in the oxide-form the smaller is the value of X in the salt-form. The following symbols are given by Brauner (*Sitz. W. [Math.-naturwiss. Classe]*, 84, 1165):—

Groups .	I.	II.	III.	IV.
Oxide forms .	$RX, RX_2,$	$RX,$	$RX,$	$RX,$
Salt forms .	$RX,$	$RX,$	$RX,$	$RX,$
Groups .	V.	VI.	VII.	VIII.
Oxide forms .	$RX,$	$RX,$	$RX,$	$RX,$
Salt forms .	$RX,$	$RX,$	$RX,$	$RX,$

The characteristic oxides of most of the elements belonging to Group I., Li . . . Au, are represented by the general symbol  $R_2O$ ; putting  $X = \frac{O}{2}$ , the ratio of metal to O in these oxides

is expressed by the symbol  $RX$ . Similarly the composition of the characteristic oxides of the elements of Group II., Be . . . Hg, is represented by  $RO$ ; but, as  $O = X$ , the symbol  $RX$  expresses the same composition as the symbol  $RO$ . The salt-forms,  $RX, \dots RX$ , are inter-

preted in the same way as the oxide-forms. Thus Na forms a hydrated hydroxide of the composition  $\text{Na.OH.3H(OH)}$ ; now, if  $X = \text{H} = \text{OH}$ , this compound belongs to the general form  $\text{RX}_x$ ; similarly, the salt  $\text{S}_2\text{Cl}_2$  (Group VI.) belongs to the general form  $\text{RX}_x$ . These symbols must be interpreted only in a wide and general way. For instance, the highest oxide of a metal of Group I. is  $\text{K}_2\text{O}_2$ , and this belongs to the form  $\text{RX}_x$ , but the most characteristic oxides ( $\text{M}_2\text{O}$ ) of the majority of the metals of this group belong to the form  $\text{RX}_x$ ; the most characteristic oxide of copper, however, is  $\text{CuO}$ , and of gold is  $\text{Au}_2\text{O}_3$ ; these oxides belong, respectively, to the forms  $\text{RX}_x$  and  $\text{RX}_x$ . But Cu and Au are classed both in Groups I. and VIII.; the oxide form of Group VIII. is  $\text{RX}_x$ , and the salt form is  $\text{R}_2\text{X}$ ; but no well-marked oxide or salt of either Cu or Au belongs to either of these forms. So again,

Group V. has assigned to it the oxide form  $\text{RX}_x$ , and the salt form  $\text{RX}_x$ ; the oxides  $\text{N}_2\text{O}_5$ , . . .  $\text{Bi}_2\text{O}_5$ , certainly belong to the form  $\text{RX}_x$ ; the salts  $\text{NO}_2(\text{OH})$ ,  $\text{PO}_2(\text{OH})$ , &c., belong to the form  $\text{RX}_x$ ; but the salts  $\text{PO}(\text{OH})_3$ ,  $\text{Sb}_2\text{O}_5(\text{OH})_3$ , &c., belong to the form  $\text{RX}_x$ , and the salt  $\text{Bi}_2\text{O}_5\text{H}(\text{OH})$  to the form  $\text{RX}_x$ . The symbols given must then be interpreted as representing the limits between which the compositions of most of the compounds of each group vary; that with the greater value of  $X$  represents the composition of the highest compounds, and that with the smaller value of  $X$  represents the composition of the lowest compounds of the elements in any specified group. The expressions 'salt-forms' and 'oxide-forms' are not to be recommended; it would be better to summarise the facts of composition in some such way as this:—

- Limiting forms between which the composition of compounds varies.

## Groups.

I.	II.	III.	IV.	V.	VI.	VII.	VIII.
$\text{RX}_x$ to $\text{RX}$	$\text{RX}_x$ to $\text{RX}$	$\text{RX}_x$ to $\text{RX}$	$\text{RX}_x$ to $\text{RX}$	$\text{RX}_x$ to $\text{RX}$	$\text{RX}_x$ to $\text{RX}$	$\text{RX}_x$ to $\text{RX}$	$\text{RX}_x$ to $\text{R}_2\text{X}$

In Groups I. to III. the lower form usually represents the composition of what may be called the typical group oxides; in Groups V. to VIII. the higher form usually represents the composition of the typical group oxides. The 'typical group oxides' are not always the most stable oxides; e.g.  $\text{Bi}_2\text{O}_5(\text{RX}_x)$  is less stable than  $\text{Bi}_2\text{O}_3(\text{RX}_x)$  (Group V.),  $\text{PbO}_2(\text{RX}_x)$  is less stable than  $\text{PbO}(\text{RX}_x)$  (Group IV.). Sometimes these 'typical group oxides' are scarcely known to exist; e.g. no oxide of the form  $\text{RX}_x$  has certainly been obtained where R is an element of Group VII.; but the composition of the highest, and speaking broadly the most stable, acids (? acids with largest affinities) of this group of acid-forming elements is represented by the symbol  $\text{HMO}_4$  (where  $\text{M} = \text{Cl, I, or Mn}$ ), and the hypothetical anhydrides of these acids have the composition  $\text{M}_2\text{O}_7$ , that is, are represented by the symbol  $\text{RX}_x$ . Of the 11 elements which ought to find places in Group VII., only 5 are actually known; when the remaining 6 have been prepared and their compounds examined some of them may be found to form oxides belonging to

the form  $\text{RX}_x$ . Concerning Group VIII., it is difficult to say which oxides of the members of this group are to be taken as the typical group oxides; for Ni, Co, and Cu, one would be inclined to adopt the oxides  $\text{MO}(\text{RX}_x)$ , for Fe and Au the oxides  $\text{M}_2\text{O}_3(\text{RX}_x)$ , for silver the oxide  $\text{Ag}_2\text{O}(\text{RX}_x)$ , and for Os and Ru the oxides  $\text{MO}_2(\text{RX}_x)$ . The compositions of these vary between the limiting forms  $\text{RX}_x$  and  $\text{RX}$ ; there is probably a sub-oxide of silver ( $\text{Ag}_2\text{O}$ ) belonging to the form  $\text{R}_2\text{X}$ .

When we deal with compounds other than oxides, the application of the limiting forms becomes yet more difficult. If the term salt be taken to mean (1) acids, in the cases of markedly negative elements, or (2) metallic derivatives of acids, in the cases of markedly positive elements, then the characteristic salts of the elements of Group I. are represented by  $\text{Li}_2\text{SO}_4$ , and they belong to the form  $\text{RX}$ ; the characteristic salts of Group II. are represented by  $\text{BeSO}_4$ , and they belong to the form  $\text{RX}_x$ . Tabulating in this way the characteristic salts and their general symbols for the groups, we have the following result:—

Groups	I.	II.	III.	IV.
Salt .	$\text{Li}_2\text{SO}_4$	$\text{BeSO}_4$	$\text{Al}_2\text{SO}_4, \text{B(OH)}_3$	$\text{CCl}_4, \text{Sn(SO}_4)_2$
Form .	$\text{RX}$	$\text{RX}_x$	$\text{RX}_x$	$\text{RX}_x$
Group			V.	
Salt .			$\text{NO}_2(\text{OH}), \text{Bi}_2\text{NO}_3$	
Form .			$\text{RX}_x$	
Group			VI.	
Salt .			$\text{Cr}_2\text{SO}_4$ and $\{\text{UCl}_4, \text{U(SO}_4)_2\}$	
Form .			$\text{RX}_x$	
Group			VII.	
Salt .			$\text{MnSO}_4$ and $\{\text{MnO}_2(\text{OH}), \text{ClO}_2(\text{OH})\}$	
Form .			$\text{RX}_x$	
Group			VIII.	
Salt .	$\text{FeSO}_4$		$\{\text{Fe}_2\text{SO}_4, \text{AuO(OK)}\}$ and $\{\text{PtCl}_4, \text{PtCl}_2\}$	
Form .	$\text{RX}_x$		$\text{RX}_x$	
			and $\{\text{PtClSO}_4(\text{OH}), \text{PtCl}_2, \text{PtO}_2\cdot 2\text{H(OH)}\}$	
			$\text{RX}_x$	
				$\{\text{OsO(OK)H(OH)}\}$
				$\text{RX}_x$

If the term salt is used to include all compounds of a given element, whether these be classed as double salts, basic salts, hydroxides, &c., &c., then it is easy to find representatives of most forms, intermediate between the limiting group forms, for the members of any group. For instance, salts higher than  $RX$  add up to  $RX$ , belonging to Group I. are represented by  $KI$ ,  $(RX)_3$ ,  $KAuCl_4$  and  $KAuBr_4$ ,  $(RX)_3$ , and  $Na(OH).3H(OH)(RX)_3$ ; salts of the form  $RX$ , belonging to Group III. are represented by  $BOCl_3$ ,  $AlKCl_4$ , and  $AlKI_4$ ; salts belonging to Group II., of the form  $RX$ , are represented by  $MgNaF_2$  and  $BeKF_2$ , and of the form  $RX$ , by  $BeK_2F_4$ ,  $ZnK_2F_6$ , and  $BaO.H(OH)$ . It has been sought to trace special relations between the forms of hydrides and hydrated oxides in each group; thus, Mendeleeff gives the following symbols:—

Groups	I.	II.	III.
<i>Hydride form</i> . . . .	$RH$	$RH_2$	$RH_3$
<i>Example</i> . . . .	—	—	—
<i>Hydrated oxide form</i> . . . .	$RH_2O$	$RH_2O_2$	$RH_2O_3$
<i>Example</i> . . . .	$NaOH.3HOH$	$Ca(OH)_2HOH$	$\frac{Al_2O_3.5H_2O}{2}$

Groups	IV.	V.	VI.	VII.
<i>Hydride form</i> . . . .	$RH$	$RH_2$	$RH_3$	$RH$
<i>Example</i> . . . .	$CH_4$	$PH_3$	$OH_2$	$ClH$
<i>Hydrated oxide form</i> . . . .	$RH_2O$	$RH_2O_2$	$RH_2O_3$	$RHO$
<i>Example</i> . . . .	$Si(OH)_4$	$PO(OH)_3$	$SO_2(OH)_2$	$ClO_2(OH)$

The limiting forms of compounds which the periodic law supplies as an aid in classifying elements and compounds are undoubtedly useful if employed with caution. The search for such limiting forms has always been carried on in chemistry. Dalton and Berzelius made it the main business of their lives, as chemists, to seek for formulæ which should express the maximum numbers of atoms of each element capable of combining together. Berzelius developed his all-embracing system of dualism on the conception that every compound is built up of two parts, themselves either simple or complex, one of which is electrically positive towards the other (p. DUALISM). This conception at once led to that of radicles, or groups of atoms which remain so closely united throughout various chemical changes that the functions performed by them in these changes are, to all intents, the functions of single atoms. The conception of the radicle brought with it into chemistry a mode of reasoning which has been of much importance in the advances made within recent years. The group of atoms named a radicle was not known, as a rule, except as it manifested itself in the reactions of compounds supposed to be formed by the union of the radicle with other radicles or with elements. The arguments for or against an explanation of a chemical occurrence wherein radicles were regarded as taking part were necessarily based on experimental evidence which failed to bring into court the actual complex of atoms asserted to be an essential part of the mechanism of the change. Chemists became accustomed to think of certain collocations of atoms as necessary factors in this or that operation; but they attributed actual existence to these atomic groups only when mutual action and reaction was occurring between

them and other groups, or single atoms. The way was thus prepared for regarding all chemical phenomena as essentially the results of mutual actions and reactions between elements or compounds, and for the conception of chemistry as the study, not so much of this kind of homogeneous matter, or that, as of the connections between the changes of composition and the changes of properties which these kinds of matters exhibit when they mutually act and react under defined conditions. The conception of radicles went hand in hand with that of types. The meaning of a typical classification of elements and compounds has been illustrated in the present article (v. also RADICLES AND TYPES). The most complete outcome of this method is the classification based upon the periodic law; and the use of typical forms to express the com-

positions of oxides, and other compounds, of each group of elements, is one of the points wherein the periodic law emphasises the continuity of chemical science.

The great objection to the use of these typical or limiting forms seems to be that they are based too exclusively on the notion of showing the composition of compounds, and that their employment tends to hide the importance of combining the study of composition with that of properties. The purely empirical compositions of the salts  $KAuCl_4$  and  $NaOH.3H_2O$  are certainly represented by the symbols  $RX_4$  and  $RX_3$ , as illustrations of the existence of which forms in Group I. the salts in question are brought forward; but a comparison of the properties of these salts with those of such compounds as  $Au_2O_3$  and  $Na_2O$  at once shows that there is a great difference between the two classes of compounds. The mere fact that platinum forms a compound which, by the dexterous use of symbols, may be represented as belonging to the type  $RX_4$ , can be of little assistance in developing a rational scheme of classification. One of the platinum compounds of this type is  $PtClSO_4(OH)$ ; why should not this compound be used to prove that sulphur forms compounds of the type  $RX_4$ , or that chlorine forms compounds of the type  $RX_3$ ? Why is the compound  $BeK_2F_4$ , (i.e.  $BeF_2.2KF$ ) to be adduced as an example of the existence of compounds of the form  $RX_4$  in Group II., and not as an example of the existence of compounds of the form  $RX_3$  in Group I., or of the form  $RX$  in Group VII.? If empirical composition is everything, it is only necessary to write this double fluoride as  $K_2BeF_4$ , to prove that it belongs to the  $(R_2X_2X_2)$ , that is  $RX_4$ , form of Group I.; or as  $F_2BeK_2$ , to prove that it is an example of the  $(R_2X_2X_2)$ , that is  $RX$  form in Group VII.

The history of the classifications which at different times have been founded on the notion of types conclusively proves that unless attention is constantly paid to the functions, as well as to the compositions, of the bodies classified, the systems do little to further chemical advance, and the conception on which they are founded is shorn of most of its value as a science-producing idea. It is most certainly true that the classification presented by the periodic law is based on the study at once of the compositions and the functions of the bodies classified; it is this, indeed, which gives the method so marked an advantage over all others; but just because of this fact should we be ever on our guard against placing too much trust in any single part of the method, unless that part is used in conjunction with the other parts, all of which together constitute the complete method.

The forms assigned to many salts, especially to the double and basic salts, almost wholly depend on the valence given to the different elementary atoms. Why do we begin by asserting that  $X = \text{F}, \text{Cl}, \text{Br}, \text{I}, \text{NO}_2, \text{ClO}_2, \frac{\text{SO}_4}{2}, \frac{\text{PO}_4}{3}, \frac{\text{O}}{2}$ , &c.? How is the equivalency assumed to exist between these atoms and groups of atoms actually proved to exist? In writing the equations

$\text{F} = \text{Cl} = \text{Br} = \text{NO}_2 = \frac{\text{O}}{2} = \frac{\text{SO}_4}{2}$ , and in applying

these to the study of typical forms of salts, we are making many far-reaching assumptions. The chief assumptions are two. In the first place, the molecular theory is carried over from gases and applied without modification to liquids and solids. In the second place the tentative hypotheses which chemists have framed to help them to group together what they have learned from the study of gaseous compounds regarding the equivalency of atoms are applied to solid and liquid compounds. Both assumptions are made without acknowledging the great differences between the phenomena on which a theory of the structure of liquids and solids must rest, and the phenomena from which the prevailing theory of the structure of gases has been developed. The very word molecule is defined only in terms of gaseous phenomena. It is the study of gaseous phenomena that has obliged chemists to recognise two orders of small particles, the molecule and the atom; and it is from the study of the mutual actions of gases that a working hypothesis of the structure of molecules has been developed. In the article *Atomic and Molecular Weights* (vol. i. p. 349), an attempt has been made to show that the reacting chemical unit of a compound should at present be regarded as a collocation of atoms, which, under definite conditions, takes part in chemical changes as an individual existence. Admitting the existence of such collocations of atoms, it follows almost necessarily from every-day chemical facts that the groups have definite configurations, which remain unchanged throughout considerable changes of conditions; for all the facts of chemical change force us to regard most chemical properties as dependent on the relative arrangement, as well as on the nature and number, of the atoms which form the reacting units of compounds. There are few, if any, properties of bodies which, like

weight, are the sums of the properties of the atoms, and, like the volumes occupied by gaseous compounds on the other hand, are dependent only on the state of combination of the atoms. But while we admit that the chemical properties of liquid and solid compounds are partly conditioned by the configuration of the atoms which constitute their reacting units, we cannot admit, on present evidence, that these configurations do not undergo considerable changes under the influence of other kinds of matter, or of physical agencies. We rather assert that what we know of these collocations of atoms (and what we know is as nothing compared with what we do not know) favours the view that their structure is easily changed, and that in this respect they present gradations from those which are so chemically mobile as scarcely to be recognised as definite chemical individuals, to those which are so chemically stable as almost to merit the name of molecules. If then we refuse to speculate regarding the structure of the atomic groups which seem to form the reacting units of liquid and solid compounds; and if, as a consequence of this, we also refuse to admit the validity of any arrangement of the atoms of solid and liquid compounds in order of strict equivalency—for equivalency means equal value in exchange, and the chemical equivalency of atoms can only be known when we know the functions performed by the various atoms in molecules of similar structure—can we hope to learn anything definite regarding the equivalencies of the atoms which constitute the molecules of gaseous compounds?

The subject of the equivalency of atoms goes hand in hand with that of the structure of molecules. The subject is too large to be discussed in an article on classification; but it is necessary to sketch the outlines of it as sharply as possible. All gaseous molecules formed by the union of atoms of *hydrogen, fluorine, chlorine, bromine, and iodine* are formed of two atoms; the molecules in question are these:  $\text{H}_2, \text{Cl}_2, \text{Br}_2, \text{I}_2, \text{HF}, \text{HCl}, \text{HBr}, \text{HI}$  (at very high temperatures the molecule of iodine is monatomic).

Those atoms which combine each with a single other atom to form a gaseous molecule are called *monovalent atoms*; the standard monovalent atoms are  $\text{H}, \text{F}, \text{Cl}, \text{Br}, \text{and I}$ . If the gaseous molecules formed by the union of atoms of  $\text{H}, \text{F}, \text{Cl}, \text{Br}, \text{or I}$ , with other atoms are tabulated, and the other atoms are then arranged in classes according as they are each found to combine with one, two, &c. atoms of  $\text{H}, \text{F}, \text{Cl}, \text{Br}, \text{or I}$ , the following arrangement results (v. next page). The atoms in column I. are monovalent; the atoms in column II. are called *divalent*, those in column III. *trivalent*, and so on. Atoms whose valencies are greater than one may be classed together as *polyvalent*. Of the 89 elements (exclusive of the 5 standard monovalent atoms) in these six columns, at least five occur each in two columns, viz.  $\text{Hg}, \text{In}, \text{P}, \text{Sn}, \text{W}$  (In probably occurs in three columns); the atoms of  $\text{Ga}, \text{Cr}, \text{and Fe}$  are probably also both divalent and trivalent.

The valency or equivalency (or quantivalence) of an elementary atom may be defined as the number which expresses the maximum number of

## Monovalent atoms—H, F, Cl, Br, I.

Atoms which produce compound gaseous molecules by union each with

I. one monovalent atom	II. two monovalent atoms	III. three monovalent atoms	IV. four monovalent atoms	V. five monovalent atoms	VI. six monovalent atoms
K, Rb, Cs, Hg, Ag, Tl, (?In).	O, S, Se, Te, Be, Cd, Zn, Hg, Sn, Pb, Mn, In, (?Ga, Cr, Fe).	B, N, P, As, Sb, Bi, In, Cr, Fe, Al, Ga.	C, Si, Ti, Ge, Zr, V, Sn, Th, U.	P, Nb, Ta, Mo, W.	W.

monovalent atoms (i.e. atoms of H, F, Cl, Br, or I) with which the given atom is found to combine to form a gaseous molecule. When bismuth combines with chlorine to form bismuthous chloride, one atom of the metal combines with three atoms of the halogen, and the molecule  $\text{BiCl}_3$  is produced. When hydrogen combines with chlorine to form hydrochloric acid, one atom of hydrogen combines with one atom of the halogen and the molecule  $\text{HCl}$  is produced. As a single atom of Bi combines with three times as many atoms of chlorine as an atom of hydrogen combines with, an atom of bismuth is said to be equivalent to three atoms of hydrogen. In the molecule formed by the union of atoms of H and Cl, viz.  $\text{HCl}$ , there must be direct mutual action and reaction between the two atoms; in the molecule formed by the union of atoms of Bi and Cl, viz.  $\text{BiCl}_3$ , there may or may not be direct mutual action between the Bi atom and each of the Cl atoms. But the atom of chlorine is monovalent (i.e. combines with a single other atom to form a molecule), by definition, and by reason of the facts on which the definition is based; the hypothesis most in keeping with the monovalency of the chlorine atom is that each atom of chlorine in the molecule  $\text{BiCl}_3$  directly acts on, and is acted on by, the atom of bismuth. Similarly, because of the existence of the molecule  $\text{SbCl}_3$ , the atom of Sb is said to be equivalent to three atoms of hydrogen; and, further, one atom of Sb is said to be equivalent to one atom of Bi. The conception of equivalency is here evidently that of equal value in exchange. One atom of Bi can be exchanged for one atom of Sb; one atom of O can be exchanged for one atom of Se; one atom of O can be exchanged for one atom of Si; one atom of Mo can be exchanged for one atom of W; and in each case the other parts of the molecules between which the exchange is effected remain unchanged. (The molecules in question are:  $\text{BiCl}_3$  and  $\text{SbCl}_3$ ;  $\text{OH}_2$  and  $\text{SeH}_2$ ;  $\text{CCl}_4$  and  $\text{SiCl}_4$ ;  $\text{MoCl}_6$  and  $\text{WCl}_6$ .) The molecules concerned in the various transactions may be said, without putting too great a strain on the words, to have similar structures. But the notion of equivalency is carried further; an atom of N cannot be exchanged for an atom of In, but the molecules  $\text{NH}_3$  and  $\text{InCl}_3$  exist; assuming that 3 atoms of Cl are strictly equivalent to 3 atoms of H, it follows that an atom of N is equivalent to an atom of In. An atom of S cannot be exchanged for an atom of O in the molecule  $\text{OCl}_2$ ; but the molecule  $\text{SH}_2$  exists, therefore, on the assumption that  $\text{H}_2$  is strictly equivalent to  $\text{Cl}_2$ ; it follows that S is equivalent to O. This conclusion is upheld by the direct exchange of S for O in the molecules  $\text{SiH}_4$  and  $\text{OH}_4$ . The conception of

equivalency is evidently stretched a little beyond its strict meaning when we say for instance that, because of the existence of the molecules  $\text{OH}_2$  and  $\text{TiCl}_4$ , an atom of Ti is equivalent to two atoms of O. But notwithstanding this, the definition of the valency of an atom which has been given may be applied to considerations regarding the structure of molecules. So far as data go, we seem justified in widening the definition of the valency of an atom, and in asserting that this number expresses the maximum number of other atoms, be they monovalent or polyvalent, with which the given atom combines to form a gaseous molecule. Underlying the word *combines* is the conception of *direct* interaction in the molecule. It is not necessary to venture on any hypothesis as to the states of motion of the atoms which form the molecule, or as to the nature of the mutual actions which occur between them; it is only necessary to distinguish direct from indirect action.

The prevailing notions regarding the structure of molecules are based on that of the valencies of atoms; and this carries with it the conception of each atom being able to act on, and be acted on by, a limited number of other atoms. These conceptions are indicated more or less clearly in the ordinary notation. Thus the so-called

structural formulae (1)  $\begin{array}{c} \text{H}_2=\text{C}=\text{C}=\text{H}_2 \\ | \\ \text{OH} \end{array}$  and

(2)  $\text{H}_2=\text{C}-\text{O}-\text{C}=\text{H}_2$  imply, that each carbon atom in either molecule acts directly on, and is directly acted upon by, 4 other atoms (the C atom is tetravalent), that each oxygen atom acts directly on, and is directly acted on by, 2 other atoms (the O atom is divalent), and that each hydrogen atom acts directly on, and is directly acted on by, a single other atom (the H atom is monovalent). But the distribution of the interatomic reactions is represented as being different in each molecule. In the first, 5 atoms of H are represented as in direct union with (i.e. as directly interacting with) atoms of carbon; the sixth atom of H is represented as in indirect union (through an atom of O) with a carbon atom; the atom of O is represented as in direct union with one carbon and one hydrogen atom. In the second molecule, all the H atoms are represented as in direct union with C atoms, and there is also direct action and reaction between the atom of O and each C atom. These formulae are arrived at after a careful study of the reactions of the compounds; they summarise these properties in the language of a special outcome of the molecular and atomic theory. It would be out of place to pursue the subject of structural formulae here (*v. FORMULAE*); these formulae are supposed to rest on the fundamental

conception of the valency of the atom of each element. This conception at once limits the number of atoms with which any specified atom can be directly combined in gaseous molecules; and it enables us to bring together under certain fairly definite expressions (which are, however, very easily misunderstood) regarding the composition of compounds, as composition is viewed by the molecular theory, many facts regarding the functions of compounds gained by the careful study of the behaviour of these compounds under different conditions (*v. EQUIVALENCY*).

We have already somewhat fully discussed the meaning to be given to the term acid; we have learnt that those compounds which contain replaceable hydrogen also contain negative elements. Many gaseous acids are known; the application to these of the conception of structure which springs from that of the equivalency of atoms leads to the view that in the molecule of an acid there is always direct mutual action between those atoms of hydrogen whose function is shortly expressed by the qualifying term *replaceable*, and one or more negative atoms or groups of atoms. Thus, in the molecules HCl, HBr, HI, HF, H(CN), there must be mutual action and reaction between the positive H atom and the negative Cl, Br, I, or F atom, or the negative group of atoms (CN). Again, the reactions of the molecule  $C_2H_2O_2$  oblige us to admit that direct mutual action occurs between the atom of replaceable hydrogen and an atom of the negative element oxygen, and that the three atoms of hydrogen which do not act as acidic hydrogen are in direct union with carbon atoms only:  $(H_3 \equiv C - C \begin{smallmatrix} \nearrow O \\ \searrow O \end{smallmatrix})$ .

A system of classification of compounds may be developed on the lines of the structure of the molecules of these compounds. If this classification is to be of much permanent value it must be limited to compounds to which the fundamental conceptions of the system can be applied. We have tried to show that this is equivalent to saying that the system must at present be limited to gaseous compounds. But the vast majority of chemical compounds, other than those of carbon, have not been gasified, and most of them appear to be incapable of existing in the gaseous state. Hence a system founded on the conception of molecular structure cannot be strictly applied at present to the bodies which come within the province of inorganic chemistry. Some of the subsidiary conceptions gained as the applications of the system to carbon compounds are developed may, however, be used as aids in classifying non-gasifiable bodies, provided always care be taken not to overstep the limits imposed by the conditions of the inquiry. Thus, arguing from the similarities of properties exhibited by acids as a class, and from what the hypothesis of molecular structure helps us to understand of the connections between the functions of particular atoms and the arrangement of all the atoms in the molecules of gaseous acids, we may conclude that, in the collocations of atoms which (by hypothesis) form the reacting units of non-gasifiable acids, there is more direct mutual action between the atoms of replaceable hydrogen and some negative atoms or groups of atoms, than between those

atoms of replaceable hydrogen and the more positive atoms of the reacting atomic complexes. Again, when we have learned from the study of the gaseous compounds of phosphorus that an atom of this element appears to be capable of directly acting on, and being acted on by, not more than five other atoms in a molecule, we may conclude that in the collocations of atoms which (by hypothesis) form the reacting units of the non-gasifiable compounds of phosphorus, each atom of this element is probably in direct union with not more than five other atoms. This tentative conclusion may then be applied to the development of limiting forms for phosphorus compounds; the compositions of these compounds may be represented so that they shall all come under the limiting form  $RX_5$ . But it is easy to forget the limits within which such a method as this is of any real help. It is easy to forget that the notion of the equivalency of atoms, on which such a conclusion as that just reached regarding the limiting forms of phosphorus compounds is really based, is a notion which, somewhat vague in itself, becomes vaguer the moment an attempt is made to apply it to discussions about solid and liquid bodies, for which only the outlines of a molecular theory have yet been drawn.

A system of classification, even of gaseous compounds, cannot be reared on the conception of atomic valency pure and simple. If one atom can directly interact with, say, four other atoms, the existence of a vast number of molecules built up by the union of this atom with those of two or three other elements becomes possible. Why do not all these molecules exist? Because, replies the hypothesis of molecular structure, the properties, and hence the possible existence, of a molecule, depend not only on the nature, number, and actual valencies, of the constituent atoms, but also on the manner in which the mutual interatomic reactions are distributed in the molecule. Besides the valencies of the atoms, it is necessary to consider the distributions of the interactions of these atoms. But how can we frame a working hypothesis regarding the distributions of the interatomic reactions which shall help us to understand the structure of the collocations of atoms with which it seems we have to deal in liquid and solid compounds? These interatomic actions may be distributed now in this way, now in that; the effect of this or that reagent may be to cause changes in the distribution of these reactions. We have as yet no solid basis of facts, or even of intelligible hypothesis on which to build. Compounds of about fifty-six elements (excluding carbon) have been gasified; as a rule, not more than six or eight compounds of each element are known in the gaseous state; about sixty of these compounds are available as data on which to base arguments regarding the valencies of perhaps forty-five elementary atoms. Supposing, then, that a system of classification of compounds is to be based strictly on the valencies of the atoms in the molecules of these compounds, the system must be restricted to 200 or 300 compounds, formed by the combinations of about fifty-six elements.

As regards the connections between atomic valencies and atomic weights, it appears that the valencies of the elementary atoms in certain

series of elements vary from a minimum value for the first member of the series to a maximum for the middle member, and back again to the minimum value for the last member of the series. Thus take series 2—Li, Be, B, C, N, O, F—the following are the valencies of the atoms of the members of this series so far as these valencies have been established on reasonably satisfactory data (the valency is in each case represented by a Roman numeral placed above the symbol of the element):—

*Groups.*

I.	II.	III.	IV.	V.	VI.	VII.
Series 2—Li <sup>I</sup>	Be <sup>II</sup>	B <sup>III</sup>	C <sup>IV</sup>	N <sup>V</sup>	O <sup>VI</sup>	F <sup>VII</sup>

It is possible that the valencies of the elementary atoms vary periodically with variations in the atomic weights of the elements. Should it be established that this is so, we shall have another illustration of the wide application and usefulness of the periodic law. But the classification which is founded on the periodic law rests on this generalisation as a whole, and not on any single property of either elements or compounds. The periodic law insists on the paramount importance of the comparative study of all the properties of elements and compounds; element must be compared with element, compound with compound. Thus, and thus alone, can we hope to gain a final system of chemical classification. Thus, and thus alone, can we expect to trace the fundamental relations which undoubtedly exist between the properties and the composition, and between the changes of properties and changes of composition, of homogeneous kinds of matter. On the basis of the periodic law a scheme of classification of the chemical elements and compounds may be raised, which exhibits (1) the composition of the compounds in so far as this can be shown in the present state of chemical knowledge; (2) the functions of the compounds, that is to say the reactions in which they take part; and (3) the connections between the compositions and the functions of the compounds; and in thus classifying the compounds of the different elements the method at the same time classifies the elements themselves. M. M. P. M.

In connection with the subject-matter of this article the following articles should be read:—**ATOMIC AND MOLECULAR WEIGHTS; CHEMICAL CHANGE; EQUILIBRIUM, CHEMICAL; EQUIVALENCY; FORMULÆ; MOLECULAR STRUCTURE OF MATTER, THEORIES REGARDING; PERIODIC LAW; PHYSICAL METHODS OF INQUIRY USED IN CHEMISTRY.** Further details of the properties of the various families of elements and their chief compounds are given in the following articles:—**ALKALINE EARTHS, METALS OF THE (Ca Sr Ba); ALKALIS, METALS OF THE (Li Na K Rb Cs, NH<sub>4</sub>—Ti); BORON; CARBON GROUP OF ELEMENTS (OSi—Ti Zr Sn Ce Pb Th); CHROMIUM GROUP (Cr Mo W U); COPPER GROUP (Cu Ag, Au); IRON, METALS OF THE (Al Ga In, Sn Y La Yb—Ti); HALOGENS, THE (F Cl Br I, CN—Mn); HYDROGEN; IRON GROUP (Fe Ni Co—Mn); LEAD; MAGNESIUM GROUP (Be, Mg Zn Cd, Hg); NITROGEN GROUP (N P As V Nb Sb Bi Er Bi); NOBLE METALS (Au, Hg Ru Pd, Os Ir Pt); OXYGEN GROUP (O S Se Te—Cr Mo W U); TIN GROUP (Sn Ge Pb); TITANIUM GROUP (Ti Zr Ce Th).**

The following memoirs and books may be consulted by those who wish to trace the develop-

ment of the various schemes of chemical classification which have from time to time prevailed in the science:—

OSTWALD, *Lehrbuch der allgemeinen Chemie*. (1885-87).

PATTISON MUIR, *Treatise on the Principles of Chemistry* (1884; 2nd edit. 1889).

THOMSEN, *Thermochemische Untersuchungen* [4 vols. 1882-86]. Condensed accounts of the bearings of thermochemical investigation on chemical classification will be found in Jahn's *Die Grundsätze der Thermochemie* (1882), and in Pattison Muir's *Elements of Thermal Chemistry* (1885).

CLOVES, OIL OF. Contains eugenol  $C_{10}H_{12}O_2$ , and a terpene  $C_{10}H_{16}$  (254° cor.); V.D. 7.7 (Ettling, *A.* 9, 68; Brüning, *A.* 104, 205; Williams, *A.* 107, 242; Church, *C. J.* 28, 113). The terpene is converted by Br into  $C_{10}H_{16}Br_2$  (250°-260°) (Beckett & Wright, *C. J.* 29, 1).

CNICIN  $C_{15}H_{15}O_3$  (?). Occurs in the leaves of *Centaurea benedicta* or *Onicis benedictus* and bitter plants of the order *Compositae* sub-order *Cynarocephala* (Morin, *J. Chim. Méd.* 3, 105; Scribe, *C. R.* 15, 803). Silky needles, with bitter taste; v. sol. alcohol, v. sl. sol. ether; sl. sol. hot water. Dextro-rotatory,  $[\alpha] = 181^\circ$  (Bouchardat). Its solution is rendered turbid by long boiling.  $H_2SO_4$  forms a blood-red solution. Conc.  $HCl$  becomes green, and deposits a resin on warming.

COAL TAR. The oily product of the distillation of coal contains benzene, toluene, *o*-, *m*-, and *p*-, xylene, naphthalene, anthracene, phenol, *o*-, *m*-, and *p*-, cresol, and ammonia. The minor constituents are water, hydrogen, nitrogen, carbonic oxide,  $CO_2$ , cyanogen,  $OS_2$ ,  $H_2S$ ,  $HCN$ ,  $CO$ , methane, ethylene, acetylene, propylene, allylene, butylene, crotonylene, amylene, hexyl-

ene, hexinene, ennane, decane, styrene, mesitylene,  $\psi$ -cumene, terpenes, naphthalene dihydride, methyl-naphthalene, di-methyl-naphthalene, diphenyl, acenaphthene, fluorene, phenanthrene, fluoranthene,  $\psi$ -phenanthrene, methyl-anthracene, pyrene, chrysene, piceone, acetic acid, acetonitrile, thiophene, methyl-thiophene, di-methyl-thiophene, phenyl thiocarbimide, pyrocresols, carbazole, phenyl-naphthyl-carbazole (phenylene-naphthylene-imide), xylenol, benzoic acid, ( $\alpha$ )- and ( $\beta$ )-naphthol, pyridine, pyrrole, methyl-pyridine, di-methyl-pyridine, tri-methyl-pyridine, aniline, quinoline, methyl-quinoline, parvoline, coridine, rubidine, viridine, lepidine, cryptidine, and acridine (cf. Schultz, *Die Chemie des Steinkohlentheers*). Many of the hydrocarbons present in coal tar are probably formed from phenols by splitting off water, and reduction (Schulze, *A.* 227, 152). Others are formed by the action of heat on simpler hydrocarbons. Thus marsh gas is converted by passage through a red-hot tube into benzene, propylene, and naphthalene; ethane gives  $C_2H_4$  and hydrogen; ethylene gives ethane and acetylene; acetylene gives hydrogen, ethane, ethylene, benzene, styrene, and naphthalene; benzene gives diphenyl and hydrogen; while a mixture of benzene and ethylene gives anthracene (Berthelot, *A.* 142, 254; Schultz, *A.* 174, 203; 203, 118). Most of the bases are probably formed either by the action of ammonia on the phenols, or by the condensation of bases so formed with themselves, with other bases, with phenols, or with unsaturated hydrocarbons.

COBALT Co. At. w. 58.8. Mol. w. unknown as element has not been gasified. [ $c. 1500^\circ$ ] (Pictet, *C. R.* 88, 1317). S.G. 8.5-8.7 (v. Playfair & Joule, *C. S. Mem.* 3, 57). S.G. 8.96 (Rammelsberg, *P.* 78, 93). S.H. 107 (Regnault, *A. Ch.* [3] 63, 5).  $V_1 = V_0 (1 + 3 \times 0.0001236t)$ ,  $t = 40^\circ$  (Fizeau, *C. R.* 68, 1125). E.C. at  $0^\circ$  (Hg at  $0^\circ = 1$ ) 9.685 (Matthiesen & Vogt, *P. M.* [4] 26, 242). T.C. ( $Ag = 100$ ) 17.2 (Barrett, *J.* 1873, 181). S.V.S. c. 6.84. H.C. [ $Co_2O_3 \cdot 3H_2O$ ] = 149,380 (*Th.* 3, 306).

Occurrence.—The metal is found in small quantities (1 p.c.) in some meteorites. Chiefly as *smaltine*,  $CoAs$ , in which Co is more or less replaced by Ni and Fe; and *cobalt-glance*,  $CoAsS$  with Co partially replaced by Fe and Ni, Co compounds also occur as oxide, sulphate, arsenate, &c., chiefly with compounds of Ni, Fe, and Mn. Compounds of Co were used for producing blue glasses in ancient times. 'Smalt' was prepared in Saxony in the 16th century. Cobalt was first recognised as an element by Brandt in 1735. The name is said to be derived from 'Kobold' (= sprite or goblin) a term applied by miners in the middle ages to minerals which were employed in the arts, but from which no useful metal could be extracted.

Formation.—The ore is roasted to partly remove arsenic and sulphur; the residue is dissolved in  $HCl$  with a little  $HNO_3$ ; Fe is ppt. by  $CaO$ ,  $H_2$ , Cu, Bi, &c. are ppt. by  $H_2S$ ; addition of bleaching powder then pps.  $Co_2O_3 \cdot xH_2O$ ; this is heated, and the  $Co_2O_3$  formed is reduced by heating with charcoal.

Preparation.—1. The chief impurities to be removed are As and other metals ppt. by  $H_2S$ , Fe, and Ni. The roasted ore freed from

gangue may be fused with nitre, treated with water to dissolve K arsenate, the residue dissolved in *aqua regia*, evaporated, diluted, saturated with  $H_2S$ , and filtered; the filtrate may then be mixed with so much of a ferric salt that a brown pp. (ferric arsenite and  $Fe_2O_3 \cdot H_2O$ ) forms on partial neutralisation,  $K_2CO_3$  aq. is then added so long as the pp. is brown, and until a few drops of the filtrate give a reddish pp. (showing ppn. of Ni) with alkali; almost every trace of As is thus removed; the filtrate may be acidulated with HCl and reppd. by  $H_2S$ . To the filtrate (which should be only slightly acid) solution of bleaching powder or NaClO is added, so long as the pp. is black ( $Co_3O_4$ ), a reddish-brown colour indicates ppn. of Ni oxides; the pp. is washed, and dissolved in nitric acid, the liquid is concentrated and neutralised by KOH, mixed with  $KNO_3$  aq., strongly acidified by acetic acid, and allowed to stand for a few days; the pp. of K-Co nitrite is washed, dried, and strongly heated; K is removed by washing with water; the residual Co oxide is dissolved in oxalic acid, and the Co oxalate is reduced by strongly heating in a closed crucible (Hermstädt, *J. pr.* 31, 105; Patera, *J. pr.* 67, 14).—2. The oxide, prepared as described in 1, is reduced in a stream of H at temp. above  $320^\circ$  (Müller, *P.* 136, 51).—3. The oxide is dissolved in HCl aq. and the solution is evaporated to crystallisation, the crystals of  $CoCl_2 \cdot 6H_2O$  are dried and heated in a stream of Cl; and the  $CoCl_2$  thus obtained is reduced by heating in H (Peligot, *C. R.* 19, 670).—4. A solution of the oxide is saturated with  $NH_4$  oxalate, and the liquid is warmed, a little solid  $NH_4$  oxalate is dissolved in the hot liquid which is then electrolysed, using a Pt basin as negative, and a piece of Pt foil as positive, electrode (Classen & Von Reis, *B.* 14, 1622).

**Properties.**—Steel-grey, lustrous, crystalline plates; nearly white when polished; hard; somewhat malleable; very ductile at red heat and upwards; slightly magnetic, even at full red heat (Pouillet). The compact metal does not oxidise in air at ordinary temperatures, but when heated it forms  $Co_3O_4$ ; the finely divided metal obtained by reducing the oxide or chloride in H at moderate temperatures is pyrophoric. Combines directly with Cl. Oxidised superficially by  $H_2O_2$  aq. Decomposes steam at red heat, and  $NH_3$  to N and H. Dissolves in mineral acids forming cobaltous salts. Cobalt wire heated till superficially oxidised, and at once plunged into fuming nitric acid, does not dissolve; it shows 'passivity' (Nickles, *C. R.* 38, 284) due either to the formation of a protecting layer of N oxides, or to a layer of cobalt oxide (*cf. passivity of iron, under Iron*). Co in thin leaves is said to absorb H much as Pd does (Böttcher, *J.* 1874. 295).

Cobalt is distinctly metallic in its chemical behaviour;  $CoO$  forms a series of well-marked normal salts, many basic salts are also known;  $Co_2O_3$  dissolves in acids probably forming salts, but these are very soon decomposed to cobaltous salts; double cobaltic salts are, however, stable, e.g.  $Co(NO_3)_2 \cdot 6KNO_3$  (*v. also COBALTIMINES*). When  $CoO$  is added to molten KOH, the compound  $(CoO)_2 \cdot K_2O$  is said to be produced, in which Co forms part of the acid radicle (*v. COBALTTATES*). The sulphides of Co show no acidic character.

The atomic weight of Co has been determined (1) from analyses of the sulphate and chloride (Mariñac, *Ar. Sc.* 1, 373); (2) by reduction of  $CoO$  in H (Russell, *C. J.* (2) 1, 51); (3) by reduction of  $NH_4$ -Co cyanide and phenylammonium cobalt cyanide (Weselsky, *B.* 2, 592); (4) by reduction (by heat) of strychnine- and brucine-cobalt cyanide (Lee, *C. N.* 24, 234); (5) by reducing  $CoO$  in H (Zimmermann, *A.* 232, 824). Determinations of the S.H. have shown that 58.8 and not a multiple of this number is to be adopted. This result has been confirmed by the isomorphism of several Co salts with the corresponding salts of Ni and Fe.

Cobalt is very closely related in its chemical properties to Ni; it is classed with this metal and Fe, and it also shows analogies with Mn; *v. IRON GROUP OF ELEMENTS*.

**Reactions and Combinations.**—1. With steam at red heat forms  $CoO$  and  $H_2$ .—2. Strongly heated in air burns to  $Co_3O_4$ .—3. Decomposes ammonia at red heat to N and  $H_2$ .—4. Dissolves in mineral acids with formation of salts; with  $H_2SO_4$  evolves  $SO_2$ , and with  $HNO_3$  gives N oxides. Thomsen (*Th.* 3, 306) gives these thermal data;  $[Co, H^2SO_4 \text{ aq.}] = 19,710$  giving  $CoSO_4 + H_2$ ;  $[Co, H^2Cl \text{ aq.}] = 16,190$ .—5. Combines with chlorine, bromine, and iodine, by heating in contact with these elements, forming  $CoCl_2$ ,  $CoBr_2$ , and  $CoI_2$ , respectively.  $[Co, Cl^2] = 76,480$ ;  $[Co, Cl^2 \text{ aq.}] = 94,820$ ;  $[Co, Br^2 \text{ aq.}] = 72,940$ ;  $[Co, I^2 \text{ aq.}] = 42,520$  (*Th.* 3, 306).—6. Heated with sulphur forms  $CoS$  and  $Co_3S_2$ .—7. Combines with selenium to form  $CoSe$ , by heating the two elements together (*v. COBALZ, SELENIDE OR*).—8. Combines with arsenic (*v. COBALZ, ARSENIDES OR*).—9. Absorbs (? combines with) small quantities of carbon when strongly heated with it, forming a hard grey mass resembling steel.—10. Forms alloys with several metals, especially Sb, Bi, Au, Fe, Pb, Pt, Ag, Sn, and Zn; little is known of these bodies.

**Detection and estimation.**—Co compounds give a clear blue colour with a bead of borax or microcosmic salt in both blowpipe flames. Black  $CoS$  is ppd. by alkaline sulphides, but not by  $H_2S$  in acid solutions. Ammonia pps. blue basic salts, soluble in excess to a reddish liquid which absorbs O from the air and becomes brownish; KOHAq pps. part of the Co as hydrated oxide from this solution. Traces of Co are detected by adding excess of  $NH_4$  aq. and then  $K_2FeC_4$  aq. when a dark yellowish red colour is produced (Skey, *C. N.* 15, 111); or by adding excess of KCNAq followed by  $NH_4$  sulphide, when a blood-red colour is formed which slowly disappears (Tattersall, *C. N.* 39, 66; Papasogli, *B.* 12, 297). Co may be estimated by ppn. as oxalate, which is then decomposed by heat to metal. The Co may be separated from Ni by evaporating an acid solution to a small bulk, adding slight excess of KOHAq, acidifying with acetic acid, adding excess of a conc. solution of  $KNO_3$ , strongly acidified by acetic acid, allowing to stand for 24 hours in a warm place, and washing the ppd.  $Co(NO_3)_2 \cdot 6KNO_3$  with solution of 1 part K acetate in 9 parts  $H_2O$ . The pp. is dissolved in HCl aq.; liquid is evaporated until very conc. and all free acid is removed,  $K_2CO_3$  aq. is added drop by drop until the pp. which forms is dissolved, a little water is added, the liquid is

heated to boiling, and rather more than an equal volume of 80 p.c. acetic acid is added *very slowly*; after standing 6 hours at about 50° the ppd. Co oxalate is filtered off, washed with a mixture of equal volumes of conc. acetic acid, alcohol, and water, and dried; it is heated in a closed crucible, then strongly in the air (to oxidise C), and the oxide is reduced by strongly heating in H. After weighing, the Co should be washed in hot water and again heated in H (Classen, *Fr.* 18, 189). Classen recommends the electrolytic estimation of Co by depositing the metal from a solution in excess of warm  $K_2C_2O_4$  Aq (v. Classen's *Quantitative Analyse durch Electrolyse*, Berlin, 1886. A description of the apparatus will be found in Dittmar's *Exercises in Quantitative Chemical Analysis*, Glasgow, 1887). Wolff (*Fr.* 18, 38) proposes to determine minute quantities of Co by a spectroscopic method based on the absorption-spectrum of very dilute solutions of Co to which excess of  $NH_4Aq$  and a little  $NH_4SCy$  have been added.

**Technical applications.**—By adding a fraction of a per cent. of Mg to Co an easily worked metal is obtained, which is very compact and lustrous, and resists the action of the air (Fleitmann, *B.* 12, 454; *Biedermann's Chem.-techn. Jahrb.* 1884-5, 25). Many metals may be covered with a thin deposit of Co by electrolysing a fairly conc. solution of  $CoCl_2 \cdot NH_4Cl$  (Böttcher, *W. J.* 1878, 219; Gaiße, *C. R.* 87, 100) (v. COBALT COLOURING MATTERS, p. 229).

**References.**—Besides those in the text the following are of importance: (1) Regarding the metallurgy and preparation of Co; Manhès (*B.* 17, 622), Wöhler (*P.* 6, 227), Liebig (*P.* 18, 164), Langier (*A. Ch.* 9, 267), Stromeyer (*A.* 96, 218). (2) Regarding the properties of Co; Deville (*D. P.* 140, 428), Barrett (*J.* 1873, 131). (3) Regarding technical applications of Co; Wiggin (*W. J.* 1881, 69; v. also *W. J.* 1883, 149). **Cobalt, arsenides of.** Co and As are said to form a grey-black, porous, mass, when heated together in the ratio of 2 parts Co to 3 parts As. The mineral *smaltine* is more or less pure Co arsenide,  $CoAs_2$ ; and *skutterudite* is nearly pure  $CoAs_3$ .

**Cobalt, arsenite of.**  $Co_2H_2(AsO_3)_2 \cdot H_2O$ ; v. vol. i. p. 806.

**Cobalt, borate of.** Probably  $2CoB_2O_7 \cdot CoO \cdot H_2O \cdot 3H_2O$  (H. Rose, *P.* 88, 299).

**Cobalt, bromide of.**  $CoBr_2$ . Mol. w. unknown.  $[Co, Br^2, Aq] = 72,940$  (*Th.* 8, 306). A green, deliquescent, lustrous solid; prepared either by heating Co in Br vapour (Rammelsberg, *P.* 56, 244); or by warming Co in contact with Br and  $H_2O$ , evaporating over  $H_2SO_4$ , drying the crystals

of  $CoBr_2 \cdot 6H_2O$ , and heating to c. 180° (Hartley, *C. J.* [2] 12, 214). The crystals of  $CoBr_2 \cdot 6H_2O$  melt at 100°, giving the purple-grey hydrate  $CoBr_2 \cdot 2H_2O$  (Hartley).  $CoBr_2$  absorbs  $NH_3$ , forming  $CoBr_2 \cdot 6NH_3$ , from which all  $NH_3$  can be removed by heat (v. COBALTAMINES).  $CoBr_2Aq$  and  $PtBr_2Aq$  evaporated yield carmine, rhombohedral, very deliquescent, crystals of  $CoBr_2 \cdot PtBr_2 \cdot 12H_2O$ ; S.G. 2.763 (Topsøe, *J.* 1868, 275).

**Cobalt bromide, hydrated; v. COBALT, BROMIDE or.**

**Cobalt, carbides of.** Co absorbs C when heated with charcoal, forming a hard, grey, steel-like solid. It is not known whether definite carbides are formed or not.

**Cobalt, chloride of.**  $CoCl_2$ . Mol. w. unknown.  $[Co, Cl^2] = 76,480$ ;  $[CoCl^2, Aq] = 18,340$  (*Th.* 3, 306). Absorption-spectrum, v. Russell, *Pr.* 32, 258.

**Preparation.**—1.  $CoO$ , or  $CoCO_3$ , is dissolved in dilute  $HClAq$ , the solution is evaporated until a blue-green solid separates, which is sublimed in a stream of dry Cl or dry  $HCl$ .—2. Finely divided Co or  $CoS$  is heated in a stream of  $Cl$ .—3.  $CoCl_2 \cdot 6H_2O$ , obtained by crystallising solution of  $CoO$  in  $HClAq$ , is heated to 120°; traces of oxychloride are always formed thus (Potilitzin, *B.* 17, 276).

**Properties and Reactions.**—Blue crystalline scales: easily soluble in water forming reddish liquid, also in absolute alcohol.  $CoCl_2Aq$  of different S.G. contains as follows (Franz, *J. pr.* [2] 5, 274):—

S.G.	$CoCl_2$ p.c.	S.G.	$CoCl_2$ p.c.
1.0496	5	1.2245	20
1.0997	10	1.3002	35
1.1579	15	1.3613	saturated at 17.5°.

A saturated alcoholic solution contains 23.6 p.c.  $CoCl_2$ , appears blue by reflected light and almost black by transmitted light, becomes colourless when diluted so that one part  $CoCl_2$  is contained in 10,000 parts of solution, but blue colour returns on warming; S.G. of this solution is 1.0107. Addition of water to the blue alcoholic solution produces violet and then red colour; a method of determining water in alcohol or in organic compounds miscible with alcohol has been founded on this reaction (Winkler, *J. pr.* 91, 209). An aqueous solution of  $CoCl_2$  becomes blue on addition of conc.  $HClAq$ ,  $H_2SO_4$ , or other dehydrating agent; also on heating, the temperature of change being the lower the more conc. is the solution, thus a 50 p.c. solution changes colour at 60°–100°, a 25 p.c. solution at 85°–135°, and a 10 p.c. solution at 180°–207° (Tichborne, *J.* 1872, 27). Addition of  $HCl$  to conc.  $CoCl_2Aq$  pps. crystals containing from 1 to  $1\frac{1}{2}$   $H_2O$  (Ditte, *A. Ch.* [5] 22, 551). The change of colour of solution of  $CoCl_2$  from blue to red is accompanied by hydration (Potilitzin, *B.* 17, 276); it is not an isomeric change as supposed by Bensch (*W. A. B.* 56, 724).

**Combinations.**—1. With water to form various hydrates (v. Potilitzin, *B.* 17, 276). The hexahydrate,  $CoCl_2 \cdot 6H_2O$ , separates by carefully evaporating a red solution of  $CoO$  or  $CoCO_3$  in  $HClAq$ ; dark red monoclinic crystals; S.G. = 1.84; lose water at 30°–35°, and at 45°–50° form the dihydrate; slowly lose water over  $H_2SO_4$ , forming the dihydrate;  $[CoCl^2, 6H_2O] = 31,190$ ;

[ $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ , Aq] = -2850 (Th. 3, 806). The dihydrate,  $\text{CoCl}_2 \cdot 2\text{H}_2\text{O}$ , forms a rose-red finely crystalline powder; prepared as described above; absorbs water from the air forming the hexahydrate. The monohydrate,  $\text{CoCl}_2 \cdot \text{H}_2\text{O}$ , is obtained by heating the dihydrate to c.  $100^\circ$ , or by slowly evaporating a solution in absolute alcohol of the hexa- or di-hydrate, the temperature being gradually raised to  $95^\circ$ . Lustrous, violet-blue, crystalline needles: dehydrated at  $110^\circ$ - $120^\circ$ .—2. With ammonia to form the compounds  $\text{M} \cdot 6\text{NH}_3$ ,  $\text{M} \cdot 4\text{NH}_3$ , and  $\text{M} \cdot 2\text{NH}_3$ , where  $\text{M} = \text{CoCl}_2$  (v. COBALTIMINES).—8. With ammonium chloride to form  $\text{CoCl}_2 \cdot \text{NH}_4\text{Cl} \cdot 6\text{H}_2\text{O}$ ; prepared by evaporating a mixture of solution of  $\text{CoO}$  in 2 parts  $\text{HClAq}$  and  $\text{NH}_3$  in 1 part  $\text{HClAq}$  (Hantz, A. 66, 284); not obtained from mixed solutions of  $\text{CoCl}_2$  and  $\text{NH}_4\text{Cl}$  (Merriek, J. 1876. 251); forms ruby-red, deliquescent crystals.—4. With aniline, paratoluidine, and xylidine. The aniline compounds are  $\text{CoCl}_2(\text{C}_6\text{H}_5\text{NH}_2)_2$  and  $\text{CoCl}_2(\text{C}_6\text{H}_4\text{NH}_2)_2 \cdot 2\text{C}_6\text{H}_5\text{O}$ ; the former, lustrous blue crystals, is obtained by dissolving  $\text{CoCl}_2$  in hot aniline and crystallising from absolute alcohol; the latter, rose-red leaflets, by adding aniline to an alcoholic solution of  $\text{CoCl}_2$ ; at  $100^\circ$  alcohol is completely removed. The toluidine and xylidine compounds, obtained similarly to the aniline compound, are blue needles:  $\text{CoCl}_2(\text{C}_6\text{H}_4\text{OH}_2\text{NH}_2)_2$  and  $\text{CoCl}_2(\text{C}_6\text{H}_3(\text{CH}_3)_2\text{NH}_2)_2$  (Lippmann, A. 11, 1069; 12, 79).—5. With cadmium chloride, gold chloride, and zinc chloride to form  $\text{CoCl}_2 \cdot 3\text{CdCl}_2 \cdot 12\text{H}_2\text{O}$ ,  $\text{CoCl}_2 \cdot 2\text{AuCl}_3 \cdot 8\text{H}_2\text{O}$ , and  $\text{CoCl}_2 \cdot \text{ZnCl}_2 \cdot 6\text{H}_2\text{O}$ , respectively; by evaporating mixed solutions of the constituent chlorides.—6. With cobaltous oxide; when dilute  $\text{NH}_4\text{Aq}$  is added drop by drop to boiling  $\text{CoCl}_2\text{Aq}$  a blue pp. is formed, which turns peach-red; this pp. when dried probably has the composition  $2\text{CoCl}_2 \cdot 6\text{CoO} \cdot 7\text{H}_2\text{O}$  (Habermann, M. 5, 442).

Cobalt chloride, hydrated; v. COBALT, CHLORIDE OF; Combinations, No. 1.

Cobalt, chromates of; v. CHROMATES.

Cobalt, cyanides of, also Cobalto- and Cobalticyanides; v. CYANIDES.

Cobalt, fluoride of,  $\text{CoF}_2 \cdot 2\text{H}_2\text{O}$ . Mol. w. unknown. Rose-red crystals; by dissolving  $\text{CoO}$  in excess of  $\text{HFAq}$ ; soluble in Aq containing  $\text{HF}$ , or in a little cold water; decomposed by much hot water to oxyfluoride  $\text{Co}_2\text{OF}_2 \cdot \text{H}_2\text{O}$  (Berzelius). Combines with potassium fluoride, sodium fluoride, and ammonium fluoride, to form double salts;  $\text{CoF}_2 \cdot \text{KF} \cdot \text{H}_2\text{O}$ ,  $\text{CoF}_2 \cdot \text{NaF} \cdot \text{H}_2\text{O}$ , and  $\text{CoF}_2 \cdot 2\text{NH}_4\text{F} \cdot 2\text{H}_2\text{O}$  (Berzelius; Wagner, B. 19, 897).

Cobalt, haloid compounds of.—These compounds all belong to the form  $\text{CoX}_2$ ;  $\text{X} = \text{F}$ ,  $\text{Cl}$ ,  $\text{Br}$ , or  $\text{I}$ . None has been gasified, and therefore the molecular weight of none is known with certainty. These compounds are greenish-blue solids; all form hydrates, which are reddish. All are soluble in water, and all seem to form double compounds with alkali haloid compounds. A very few oxyhaloid compounds have been prepared.

Cobalt, hydrated oxides of; v. COBALT, OXIDES AND HYDROXIDES OF.

Cobalt, hydroxides of; v. COBALT, OXIDES AND HYDROXIDES OF.

Cobalt, iodide of,  $\text{CoI}_2$ . Mol. w. unknown. A black, graphite-like, solid; obtained by digesting  $\text{Co}$  with water and iodine, filtering, evaporating the red liquid till it gets thickish, cooling over  $\text{H}_2\text{SO}_4$ , and heating the crystals to  $180^\circ$  (Hartley, C. J. [2] 12, 502). The liquid prepared as described yields green crystals of  $\text{CoI}_2 \cdot 2\text{H}_2\text{O}$ ; these are exceedingly deliquescent. When the same solution is kept at  $16^\circ$  or so for some days red crystals of  $\text{CoI}_2 \cdot 6\text{H}_2\text{O}$  separate (Hartley; Erdmann, J. pr. 7, 354; Rammelsberg, P. 48, 155).  $\text{CoI}_2$  combines with  $\text{NH}_3$  to form  $\text{CoI}_2 \cdot 4\text{NH}_3$  (Rammelsberg, P. 55, 245).

Cobalt, oxides and hydroxides of.—Cobalt forms three well-marked oxides:  $\text{CoO}$ ,  $\text{Co}_2\text{O}_3$ , and  $\text{Co}_3\text{O}_4$ ; four other oxides are known, which are usually regarded as compounds of the first and third of these, viz.  $\text{Co}_2\text{O}_3 \cdot 2\text{CoO}$ ,  $\text{Co}_2\text{O}_3 \cdot 3\text{CoO}$ ,  $\text{Co}_2\text{O}_3 \cdot 4\text{CoO}$ , and  $\text{Co}_2\text{O}_3 \cdot 6\text{CoO}$ . The monoxide  $\text{CoO}$  is distinctly basic; the sesquioxide  $\text{Co}_2\text{O}_3$  dissolves in acids, probably with formation of salts, but very few salts corresponding to this oxide have been obtained as they are very easily reduced to salts of  $\text{CoO}$ ; the other oxides do not form corresponding salts. The monoxide is stable when heated to a moderate temperature, but at full redness it is oxidised to  $\text{Co}_2\text{O}_3$ ;  $\text{Co}_2\text{O}_3$  is deoxidised by heating strongly with formation of  $\text{Co}_3\text{O}_4$ . Several hydrates of the various oxides are known.

I. COBALTOUS OXIDE  $\text{CoO}$ . (Cobalt monoxide, cobalt oxide.) Mol. w. unknown. A greenish-brown powder, slightly hygroscopic. S.G. 5.59 to 5.75 (Playfair, A. Joule, C. S. Mem. 3, 57). Prepared by heating  $\text{CoCO}_3$  or  $\text{Co(OH)}_2$  (q. v.) in complete absence of air (Beetz, P. 61, 478); or by heating  $\text{CoCl}_2$  in steam (Schwarzenberg, A. 97, 211); or by heating  $\text{Co}_2\text{O}_3$  in a stream of  $\text{CO}$  (Russell, C. J. 16, 51).  $\text{CoO}$  is unchanged in air, but when strongly heated it is oxidised to  $\text{Co}_2\text{O}_3$ ; it is reduced to  $\text{Co}$  by heating in  $\text{H}$  or  $\text{CO}$ , or with  $\text{C}$ ; it is quickly changed to  $\text{CoS}$  by heating in  $\text{H}_2\text{S}$ .

COBALTOUS HYDROXIDE  $\text{Co(OH)}_2$ . (Cobalt hydrate. Hydrated cobaltous oxide.) [ $\text{Co}_2\text{O}_3 \cdot \text{H}_2\text{O}$ ] = 63,400 (Th. 3, 806). Obtained by adding potash to solution of a cobaltous salt in absence of air; the pp. is a blue basic salt, which slowly changes to the rose-red hydrate; the change is quickened by heating (Winkelblech, A. 13, 148, 258; Beetz, P. 61, 478). If potash is added to a boiling solution the pp. contains alkali and some basic salt (Fremy, A. 80, 277; 83, 227, 289). A rose-red powder; absorbs  $\text{O}$  from air turning brown; heated in absence of air gives  $\text{CoO}$ . Cobaltous oxide and hydroxide dissolve in acids forming stable cobaltous salts (v. COBALT, SALTS OF, p. 221). [ $\text{CoO} \cdot \text{H}^2 \cdot \text{H}^2\text{SO}_4\text{Aq}$ ] = 24,670; [ $\text{CoO} \cdot \text{H}^2 \cdot \text{H}^2\text{Cl}_2\text{Aq}$ ] = 21,140 (Th. 3, 807).

II. COBALTIC OXIDE  $\text{Co}_2\text{O}_3$ . (Cobalt sesquioxide. Cobalt peroxide.) Mol. w. unknown. A steel-grey, lustrous solid. Heated in air gives  $\text{Co}_3\text{O}_4$ . Dissolves in conc. acids, but very few salts have been obtained corresponding to the oxide; solution in conc. cold acetic acid gives brown pp. of  $\text{Co}_2\text{O}_3 \cdot 8\text{H}_2\text{O}$  with an alkali; some double salts are known, e.g.  $\text{Co}_2(\text{NO}_3)_6 \cdot 6\text{KNO}_3$  (v. COBALT, SALTS OF, p. 221). Prepared by gently-heated  $\text{Co}_2\text{NO}_3$ , so long as reddish vapours are evolved, powdering finely and again gently heating; or by heating  $\text{Co}_2\text{O}_3 \cdot 8\text{H}_2\text{O}$  to  $600^\circ$ - $700^\circ$ .

**COBALTIC HYDROXIDES.** The compound  $\text{Co}_2(\text{OH})_2$  or  $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  is obtained by exposing a solution of a cobaltous salt, with excess of  $\text{NH}_4\text{Aq}$  added, to the air until brown, and ppg. by  $\text{KOH Aq}$ ; or by ppg. a cobaltous salt solution by a hypochlorite in presence of alkali; or by passing  $\text{Cl}$  into, or adding  $\text{Br Aq}$  to,  $\text{Co}(\text{OH})_2$  or  $\text{CoCO}_3$  suspended in water; the pp. is dried by pressing between paper. A dark-brown powder  $[\text{Co}^2+\text{O}^2+3\text{H}^+\text{O}] = 149,380$ ;  $[2\text{Co}^2+\text{H}^+\text{O}, \text{H}^+\text{O}] = 22,580$  (*Th.* 3, 306). By drying at  $100^\circ$ , or by prolonged exposure over  $\text{H}_2\text{SO}_4$ , the hydrate  $\text{Co}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$  [ $? \text{Co}_2\text{O}(\text{OH})_2$ ] is obtained. The same hydrate is formed as a black lustrous deposit on the positive pole, when a slightly alkaline solution of cobaltous-potassium tartrate is electrolysed, using Pt electrodes (Wernicke, *P.* 141, 119); S.G. as thus obtained = 2.483. The hydrate  $3\text{Co}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$  is obtained by heating  $\text{CoCl}_2$  and  $\text{Co}_2(\text{NH}_4)_2\text{Cl}_2$  in the ratio 2:1 mols., with water in a open vessel (Mills, *P.M.* [4] 35, 257).

The cobaltic hydrates lose water when gently heated, giving  $\text{Co}_2\text{O}_3$ ; when strongly heated they yield  $\text{Co}_2\text{O}_3$ . They dissolve in cold conc. acids, forming brown solutions; these solutions are decomposed on warming and thus give cobaltous salts; the solution in conc. acetic acid is fairly stable; potash pps.  $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  from this solution. Freshly ppg.  $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  dissolves in neutral  $(\text{NH}_4)_2\text{SO}_4\text{Aq}$  forming a solution of  $\text{Co}_2\text{O}_3 \cdot 10\text{NH}_4 \cdot 6\text{SO}_4$  (Geuther, *A.* 123, 157).

**III. COBALT-COBALTIC OXIDE  $\text{Co}_2\text{O}_3$ .** (*Black oxide of Cobalt*.) Mol. w. unknown. Obtained by strongly heating in air, or in  $\text{O}$ ,  $\text{CoO}$ ,  $\text{Co}(\text{OH})_2$ ,  $\text{Co}_2\text{O}_3$ , or any of its hydrates,  $\text{CoCO}_3$ ,  $\text{Co}(\text{NO}_3)_2$ , or  $\text{CoC}_2\text{O}_4$ . A black amorphous powder which slowly absorbs water from the air. S.G. 5.833-6.296 (Rammelsberg, *J.* 2, 282). Obtained as lustrous, metal-like, greyish-black microscopic octahedra, by strongly heating a mixture of  $\text{CoCl}_2$  and  $\text{NH}_4\text{Cl}$  in a stream of air or  $\text{O}$ , or a mixture of  $\text{CoC}_2\text{O}_4$  and  $\text{NH}_4\text{Cl}$  in  $\text{O}$ , and treating the residuum with hot conc.  $\text{HCl Aq}$ . The crystals are unacted on by many conc. acids, but dissolve slowly in conc.  $\text{H}_2\text{SO}_4$  (Schwarzenberg, *A.* 97, 211); they are non-magnetic.

**HYDRATES OF COBALT-COBALTIC OXIDE.** Three have been described.  $\text{Co}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , obtained by exposing to ordinary air  $\text{Co}_2\text{O}_3$ , prepared by heating  $\text{CoCO}_3$ ;  $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ , obtained by boiling a solution of roseo-cobaltic sulphate (Genth & Gibbs, *Am. S.* 23, 257);  $\text{Co}_2\text{O}_3 \cdot 7\text{H}_2\text{O}$ , obtained by allowing  $\text{Co}(\text{OH})_2$  ppg. by adding excess of alkali to a cobaltous solution to stand in the air (Fremy).

**IV. OTHER COBALT-COBALTIC OXIDES.** (i.)  $\text{Co}_2\text{O}_3 \cdot 2\text{CoO}$ ; a black powder, obtained by heating dried  $\text{CoCO}_3$  to  $100^\circ$ - $150^\circ$  in a closed crucible, or by heating luteo- or purpureo-cobalt chloride with 80-40 parts water to  $70^\circ$ - $100^\circ$  in a sealed tube (Mills, *P.M.* [4] 35, 257). (ii.)  $\text{Co}_2\text{O}_3 \cdot 3\text{CoO}$ ; obtained by heating purpureo-cobalt chloride with 2 mols.  $\text{CoCl}_2$  and some water to  $100^\circ$  in a sealed tube (Mills, *Id.*). (iii.)  $\text{Co}_2\text{O}_3 \cdot 4\text{CoO}$ ; a black powder, unchanged by boiling with  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$ , obtained by strongly heating cobaltous salts in air. (iv.)  $\text{Co}_2\text{O}_3 \cdot 6\text{CoO}$ ; obtained with  $6\text{H}_2\text{O}$  by adding  $\text{NH}_4\text{Aq}$  to  $\text{Co}(\text{NO}_3)_2\text{Aq}$  and allowing to stand in air till pp. is yellow.

**Cobalt, oxyhaloid compounds of.** Very few of these compounds have been prepared.  $2\text{CoCl}_2 \cdot 6\text{CoO} \cdot 7\text{H}_2\text{O}$ , v. COBALT, CHLORIDE OF; *Combinations*, No. 6.  $\text{CoF}_2 \cdot \text{CoO} \cdot \text{H}_2\text{O}$ , v. COBALT, FLUORIDE OF.

**Cobalt, oxysulphide of,  $\text{Co}_2\text{OS}$ .** (=  $\text{CoO} \cdot \text{CoS}$ .) Dark-grey powder; by heating  $\text{CoSO}_4$  in  $\text{H}$ . Dilute acids dissolve  $\text{CoO}$ ; conc. acids also evolve  $\text{H}_2\text{S}$ ; heated, gives  $\text{CoO}$  and  $\text{SO}_2$ .

**Cobalt, phosphide of,  $\text{Co}_2\text{P}_2$ .** Black powder; obtained by ppg.  $\text{CoCl}_2\text{Aq}$  by  $\text{Na}_2\text{HPO}_4\text{Aq}$  and heating the ppg. phosphate in a stream of  $\text{H}$ ; also by heating  $\text{CoCl}_2$  in  $\text{PH}_3$ . Insoluble in conc.  $\text{HCl Aq}$ ; easily soluble in  $\text{HNO}_3\text{Aq}$ .  $\text{Co}$  and  $\text{P}$  combine, by heating  $\text{Co}$  with a mixture of  $\text{P}_2\text{O}_5$  and charcoal.

**Cobalt, salts of. Compounds obtained by replacing the H of acids by Co.** Many of these salts are known; most of them belong to the class of cobaltous salts  $\text{CoX}$ , where  $\text{X} = \text{Cl}$ ,  $\text{NO}_3$ ,  $\text{SO}_4$ ,  $\frac{2}{3}\text{PO}_4$ , &c.; a few double cobaltic salts  $\text{CoX}_2$

are known. The  $\text{Co}$  salts are generally obtained by dissolving  $\text{CoO}$  or  $\text{CoO} \cdot \text{H}_2\text{O}$  in acids, or by double decomposition from other  $\text{Co}$  salts. Cobaltous haloid salts, sulphate, nitrate, and some others, are soluble in water; the carbonate and phosphate, &c., are insoluble.  $\text{Co}$  forms many basic salts. Aqueous solutions of cobaltous salts are generally pink; when very conc. they usually become blue to blue-green; this colour-change is accompanied by dehydration and rehydration (cf. COBALT, CHLORIDE OF; *Properties and Reactions*). For some account of the resemblances between  $\text{Fe}$ ,  $\text{Ni}$ , and  $\text{Co}$  v. *IRON GROUP OF METALS*. Cobaltous salts closely resemble  $\text{Ni}$  salts; many of them are also very similar to, and isomorphous with, ferrous salts. Cobaltic hydrate  $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  dissolves in conc. cold acids probably forming cobaltic salts; on warming, these solutions are generally quickly decomposed with production of cobaltous salts; a solution in acetic acid is fairly stable. When  $\text{KNO}_3$  is added to an acetic acid solution of a cobaltous salt a pp. of the double cobaltic salt  $\text{Co}(\text{NO}_3)_2 \cdot 3\text{KNO}_3$  is obtained. As no compound of  $\text{Co}$  has been gasified the formulae of the  $\text{Co}$  salts are not necessarily molecular. The chief salts of oxyacids are the carbonates, nitrates, phosphates, and sulphates; chlorates, bromates, iodates, nitrites, phosphites, sulphite, and a few others, are also known (v. CARBONATES, NITRATES, &c.). A great many double compounds of  $\text{Co}$  salts with ammonia are known (v. COBALTAMINES, p. 222).

**Cobalt, selenide of,  $\text{CoSe}$ .**  $\text{Co}$  and  $\text{Se}$  combine when heated together, forming a metal-like, lustrous, greyish mass, which is fusible at red heat (Berzelius). The compound  $\text{CoSe}$  is obtained by passing vapour of  $\text{Se}$  over hot  $\text{Co}$  in an atmosphere of  $\text{H}$ ; S.G. 7.66; when melted under borax it forms a yellow, crystalline, metal-like solid (Little, *A.* 112, 211).

**Cobalt, sulphides of.  $\text{Co}$  and  $\text{S}$  combine directly in different proportions.** Sulphides are also formed by adding alkali sulphides to cobaltous salts, and by passing  $\text{H}_2\text{S}$  into an acetic acid solution of  $\text{Co}_2\text{O}_3$  or  $\text{CoO}$ , and in various other ways. The following sulphides are known:  $\text{Co}_2\text{S}_3$ ,  $\text{CoS}$ ,  $\text{Co}_2\text{S}_4$ ,  $\text{Co}_3\text{S}_4$ ,  $\text{CoS}_2$ ; these are the

simplest formulae that can be given, but they are not necessarily molecular. The sulphides of Co are basic; CoS combines with  $\text{As}_2\text{S}_3$  and  $\text{Sb}_2\text{S}_3$ .

I. COBALTOUS SULPHIDE  $\text{CoS}$ . (*Cobalt monosulphide*.) Occurs native as *Syppoorite*. Prepared by heating Co with S, or CoO with S, or  $\text{CoSO}_4$  with BaS and excess of NaCl; forms bronze-coloured, lustrous needles, soluble in acids. Also obtained as a black amorphous powder by adding  $\text{NH}_3$  sulphide to an aqueous solution of a cobaltous salt, or by passing  $\text{H}_2\text{S}$  into a dilute acetic acid solution of CoO, or into water holding  $\text{Co(OH)}_2$  in suspension; the black pp. is soluble in dilute mineral acids, but not in acetic acid; insoluble in alkali sulphides; when moist it oxidises rapidly in air to  $\text{CoSO}_4$ . Non-magnetic (Hjortdahl, C. R. 65, 75). Compounds of CoS with As and Sb sulphides,  $\text{M}_2\text{S}_3 \cdot 2\text{CoS}$ , are obtained by adding Co solutions to Na thio-arsenite, &c.

II. COBALTIC SULPHIDE  $\text{Co}_2\text{S}_3$ . (*Cobalt sesquisulphide*.) Occurs native as *Cobalt-pyrites* in octahedra. Prepared by heating CoS or  $\text{Co(OH)}_2$  in a stream of  $\text{H}_2\text{S}$ , or by strongly heating a mixture of CoO, S, and KOH, and washing with water; forms a graphite-like crystalline powder. Also obtained as an amorphous black pp. by passing  $\text{H}_2\text{S}$  into a solution of  $\text{Co}_2\text{O}_3$  in acetic acid, or by adding  $\text{NH}_3$  sulphide to the solution of a roseo- or purpureo-cobalt salt. Insoluble in  $\text{KONaO}$ , thus differing from  $\text{NiS}$ .

III. COBALT DISULPHIDE  $\text{CoS}_2$ . (*Cobalt persulphide*.) *Cobalt-glance* is approximately pure  $\text{CoS}_2 \cdot \text{CoAs}_2$ . Obtained by moderately heating a mixture of 1 part dry CoO with 3 parts S, or of 1 part  $\text{CoCO}_3$  with  $1\frac{1}{2}$  parts S, until excess of S has been removed (Setterberg, P. 7, 40). A black lustrous powder; heated in absence of air to redness forms CoS; unacted on by acids except conc.  $\text{HNO}_3$  and *aqua regia*.

IV. COBALTO-COBALTIC SULPHIDE  $\text{Co}_3\text{S}_4$ . Occurs native as *Linneite*. Formed, as a greenish-black powder, by heating  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$  with K polysulphide solution to  $160^\circ$  (Sénarmont, A. Ch. [3] 80, 137).

V. The sulphide  $\text{Co}_2\text{S}_3$  is said to be obtained by heating  $\text{CoSO}_4$  to whiteness in a carbon crucible, or by strongly heating Co with S, or CoO with  $\text{H}_2\text{S}$  (Hjortdahl, G. R. 65, 75). A grey metal-like, lustrous mass, soluble in hot  $\text{HCl}$  with evolution of  $\text{H}_2\text{S}$ .

Cobalt, sulphocyanide of,  $\text{Co(SCy)}_2$ ; v. SULPHOCYANIDES, under CYANIDES.

Cobalt, borotungstate of; v. BOROTUNGSTATES, under TUNGSTEN. M. M. P. M.

COBALTAMINES. (*Cobaltammonium compounds*. *Cobalt-ammonia compounds*. *Ammonio-cobalt salts*. *Ammoniacal cobalt bases*.) Compounds of ammonia, cobalt, and negative radicals, formed either by combination of  $\text{NH}_3$  with cobaltous salts in absence of air, or by reactions between cobaltous salts and ammonia in presence of air.

Bergmann noticed the solubility of cobalt salts in ammonia. Tassart (A. Ch. [1] 28, 95, [1799]) noted that colour-changes occur when these solutions stand in the air. Thénard (A. Ch. [1] 42, 211 [1808]) and Proust (A. Ch. [1] 60, 264 [1806]) explained these changes as caused by absorption of oxygen from the air. Quantitative

measurements of the changes in question were made by L. Gmelin (S. 86, 286; Pfaff (S. 35, 486), Dingler (B. J. 10, 189), Hess (P. 26, 547), and Winkelblech (A. 13, 259). Beetz (P. 61, 489; B. J. 25, 169) and H. Rose (P. 20, 147) carried further the investigation of the compounds produced. In 1850-60 Gibbs (P. Am. A.; v. post) began his investigations of the compounds formed when ammoniacal solutions of cobalt salts are exposed to air; these researches form the basis of our knowledge of the subject. The chemists who have chiefly contributed to the elucidation of the subject of ammonio-cobalt salts, besides Gibbs, are Freymy, Claudet, Gentz, Braun, Mills, Vortmann, F. Rose, and Jørgensen (references will be given to original memoirs by these and other chemists under the individual compounds).

Some cobaltous salts combine with ammonia in absence of air, forming salts which crystallise from ammoniacal solutions but are decomposed by water; these *ammonio-cobaltous salts*, or *cobalto-amines*, generally belong to the form  $\text{M} \cdot 6\text{NH}_3$ , where M = a cobaltous compound, e.g.  $\text{CoCl}_2$  or  $\text{CoSO}_4$ . Many cobaltous salts in solution react with ammonia in presence of air to form compounds of the type  $\text{Co}_x\text{X}_y \cdot x\text{NH}_3$ , where X = an acidic radicle. These *ammonio-cobaltic salts*, or *cobalti-amines*, may be classified, primarily, according to the value of x in the general formula  $\text{Co}_x\text{X}_y \cdot x\text{NH}_3$ , and secondarily according to the nature and relation to the rest of the salt of the acidic radicle X.

Recent researches have shown that when ammonia is added to a cobaltous salt solution in presence of air, the cobaltous compound probably oxidises, and at the same time combines with ammonia, and that the various ammonio-cobaltic compounds subsequently produced are derived from these oxidised compounds by removal of oxygen and ammonia, followed in some cases by recombination with more ammonia. The final production of this or that ammonio-compound seems to depend chiefly on the relative masses of the cobaltous salt and ammonia or ammonium compound originally present.

The cobaltamines form compounds with many acids and with metallic salts. The mutual relations of the various classes of cobaltamines, and the constitution of each class, are not yet thoroughly elucidated. The following classification is a fairly satisfactory scheme of arrangement, and is generally adopted:—

I. COBALTO-AMINES or AMMONIO-COBALTOUS SALTS. Formed by the reaction of cobaltous salts in solution with ammonia in absence of air. These compounds belong to the form  $\text{M} \cdot x\text{NH}_3$ , where M = a cobaltous compound and x is generally = 6.

II. OXY-COBALTAMINES or AMMONIO-OXYCOBALTIC SALTS. Formed by prolonged oxidation of ammoniacal solutions of cobalt salts by a stream of air. Most of these compounds may be represented as belonging to one or other of the series  $\text{Co}_x(\text{NH}_3)_y \cdot \text{R}_z \cdot \text{O} \cdot \text{H} \cdot \text{O} \cdot \text{OH}$  and  $\text{Co}_x(\text{NH}_3)_y \cdot \text{R}_z \cdot \text{O} \cdot \text{OH}$ , where R = an acidic radicle

Cl, Br, I,  $\frac{\text{SO}_4}{2}$ ,  $\text{PO}_4$ , &c.

III. COBALTI-AMINES or AMMONIO-COBALTIC SALTS. Formed by exposing ammo

miscellaneous solutions of cobaltous salts to the air, and adding an acid or a salt. These compounds may be divided into four main series:—

(i.) **HEXAMINES or HEXAMMONIO-COBALTIC SALTS;**  $\text{Co}_2(\text{NH}_3)_6\text{R}_2$ , e.g.  $\text{Co}_2(\text{NH}_3)_6(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$ . These salts are also called *dichroco-baltic salts*.

(ii.) **OCTAMINES or OCTAMMONIO-COBALTIC SALTS;**  $\text{Co}_2(\text{NH}_3)_8\text{R}_2$ , e.g.  $\text{Co}_2(\text{NH}_3)_8\text{Cl}_2 \cdot 2\text{H}_2\text{O}$ .

(iii.) **DECAMINES or DECAMMONIO - COBALTIC SALTS;**  $\text{Co}_2(\text{NH}_3)_{10}\text{R}_2$ , e.g.  $\text{Co}_2(\text{NH}_3)_{10}(\text{OH})_2$ .

(iv.) **DODECAMINES or DODECAMMONIO-COBALTIC SALTS;**  $\text{Co}_2(\text{NH}_3)_{12}\text{R}_2$ , e.g.  $\text{Co}_2(\text{NH}_3)_{12}(\text{CO}_3)_2 \cdot 7\text{H}_2\text{O}$ . The fourth series is also called the series of *luteo-cobaltamines* or *luteo-ammonio-cobaltic salts*.

The octamines and decamines are generally divided each into three divisions:—

#### OCTAMINES.

(a) *Praseo-cobaltic salts*; normal salts, e.g.  $\text{Co}_2(\text{NH}_3)_8(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ .

(b) *Fusco-cobaltic salts*; basic salts, e.g.  $\text{Co}_2(\text{NH}_3)_8\text{Cl}_2(\text{OH})_2 \cdot 2\text{H}_2\text{O}$ .

(c) *Croceo-cobaltic salts*, also called *nitramines of the octamine series*; derived from praseo-salts by replacing  $\frac{2}{3}$  of R by  $\text{NO}_2$ , e.g.  $\text{Co}_2(\text{NH}_3)_8\text{SO}_4(\text{NO}_2)_2$ .

#### DECAMINES.

(a) *Roseo-cobaltic salts*; } differ in  
 $\text{Co}_2(\text{NH}_3)_{10}\text{Cl}_2 \cdot 2\text{H}_2\text{O}$  } quantity  
 } of  $\text{H}_2\text{O}$

(b) *Purpureo-cobaltic salts*; } they  
 $\text{Co}_2(\text{NH}_3)_{10}\text{Cl}_2$  } contain.

(c) *Xantho-cobaltic salts*, also called *nitramines of the decamine series*; derived from purpureo- or roseo-salts by replacing  $\frac{2}{3}$  of R by  $\text{NO}_2$ , e.g.  $\text{Co}_2(\text{NH}_3)_{10}\text{Cl}_2(\text{NO}_2)_2 \cdot 2\text{H}_2\text{O}$ .

Many cobaltamines of different classes combine with acids and with metallic salts to form double compounds.

The empirical formulæ given to the cobaltamines do not sufficiently represent the properties of these compounds. It is sometimes necessary to distinguish between the functions of different radicles in the same compound; and isomerism is exhibited by some of these bodies. Thus, in the octamine series, two octamine chlorides exist,  $\text{Co}_2(\text{NH}_3)_8\text{Cl}_2 \cdot 2\text{H}_2\text{O}$ ; one is green, it loses all its water at  $100^\circ$ , its aqueous solution is easily decomposed giving a pp. of  $\text{Co}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ ; when the solution of this salt is treated with fairly conc.  $\text{HCl}$  a violet salt crystallises out, having the same composition as the green salt; this violet salt does not begin to lose water at  $120^\circ$ , it is considerably more stable than the green salt. These two salts are representatives of two subdivisions of the division *praseo-salts*; the subdivisions are known as *octamine-praseo-salts* and *octamine-purpureo-salts* respectively. Again, in the decamine series; the chloride  $\text{Co}_2(\text{NH}_3)_{10}\text{Cl}_2$  is a violet-red solid which dissolves in water, and when digested with dilute  $\text{HCl}$  yields a red dichroic powder having the composition  $\text{Co}_2(\text{NH}_3)_{10}\text{Cl}_2 \cdot 2\text{H}_2\text{O}$ ; this salt is very unstable, it is changed to the violet-red compound on warming or on solution in water; a solution of this salt is not pptd. by  $\text{Na}_2\text{P}_2\text{O}_7$ , while a solution of the violet-red salt is pptd. by this reagent. These two salts are representatives of two divisions of the decamine series, viz. the *purpureo-*

and *roseo-decamines*. Some of the purpureo-salts crystallise with  $x\text{H}_2\text{O}$ , e.g.

$\text{Co}_2(\text{NH}_3)_{10}(\text{SO}_4)_2 \cdot \text{H}_2\text{O}$ ; but such salts lose water without undergoing essential change, hence the water is water of crystallisation, whereas in the roseo-salts the water seems to be rather water of constitution. Again, there is a compound of the purpureo-division of the decamine series,  $\text{Co}_2(\text{NH}_3)_{10}(\text{SO}_4)_2(\text{NO}_3)_2$ , which is isomeric with another compound of the same division, and both are isomeric with a roseo-salt of the decamine series. So also in one of the series of *oxy-cobaltamines*, viz. the series  $\text{Co}_2(\text{NH}_3)_8\text{R}_2\text{O.OH}$ ,  $\frac{2}{3}$  of the radicle R are more firmly held to the rest of the salt than the remaining one-fifth.

It is generally possible to give formulæ to each series, or division, which shall more or less satisfactorily represent the typical reactions of the compounds, as connected with the arrangement of the different radicles, and ammonia, relatively to the cobalt atoms; but, considering the present state of knowledge of the constitution of complex mineral compounds, such formulæ have little permanent value.

In this article accounts will be given of the leading properties of each class, series, and division, of the ammonio-cobalt compounds, and descriptions will be added of the methods of preparation of one or two of the best-known members of each group; the less-known compounds will merely be recorded. For details concerning individual compounds other than those described, reference must be made to the original memoirs. (A good account of the cobaltamines will be found in the article 'Kobalt' in Ladenburg's *Handwörterbuch der Chemie*, 5, 601 et seq.)

**Class I.—COBALTO-AMINES or AMMONIO-COBALTOUS SALTS,  $\text{M} \cdot x\text{NH}_3$ ;** M = cobaltous salt, x generally = 6. These salts were first examined by H. Rose (P. 20, 147). They are produced by combination of  $\text{NH}_3$  with dry cobaltous salts, or adding conc.  $\text{NH}_3$  to conc. solutions of cobaltous salts in absence of air; they are decomposed by heat with loss of  $\text{NH}_3$ ; their aqueous solutions also undergo decomposition, especially on warming.

**Ammonio-cobaltous chloride  $\text{CoCl}_2 \cdot 6\text{NH}_3$ ;** obtained by adding conc.  $\text{NH}_3$  to conc.  $\text{CoCl}_2$  until the blue pp. which forms is dissolved, in absence of air, and allowing to crystallise. Red octahedra; unchanged in a closed vessel; in the air, or over  $\text{H}_2\text{SO}_4$ , or by warming with  $\text{H}_2\text{O}$ ,  $\text{NH}_3$  is separated. Soluble, without change, in dilute  $\text{NH}_3$ , scarcely sol. in conc.  $\text{NH}_3$ , insol. in alcohol. The compound  $\text{CoCl}_2 \cdot 4\text{NH}_3$  is formed when  $\text{NH}_3$  is absorbed by dry  $\text{CoCl}_2$ ; and  $\text{CoCl}_2 \cdot 2\text{NH}_3$  is produced by heating  $\text{CoCl}_2 \cdot 6\text{NH}_3$  to  $120^\circ$  (H. Rose, P. 20, 147).

**Ammonio-cobaltous nitrate  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{NH}_3 \cdot 2\text{H}_2\text{O}$ ;** obtained similarly to the chloride. Red crystals, which quickly turn brown; decomposed by water with removal of  $\text{NH}_3$  (Fremy, A. Ch. [8] 85, 257).

**Ammonio-cobaltous sulphate  $\text{CoSO}_4 \cdot 6\text{NH}_3$ ;** obtained by adding alcohol to an ammoniacal solution of  $\text{CoSO}_4$  (Fremy), or by combination of dry  $\text{CoSO}_4$  with  $\text{NH}_3$  (Rose).

The compounds  $\text{CoBr}_2 \cdot 6\text{NH}_3$ ,  $\text{CoI}_2 \cdot 6\text{NH}_3$ , and  $\text{CoI}_2 \cdot 4\text{NH}_3$  are also known (Rammelsberg, P. 55, 245; 48, 155).

**Class II.—OXY-COBALTAMINES or AMMONIO-OXYCOBALTIC SALTS, or OXYCOBALTIC SALTS,  $\text{Co}_2(\text{NH}_3)_6\text{R}'_2\text{O.H.O.OH}$ , and  $\text{Co}_2(\text{NH}_3)_6\text{R}'_2\text{O.OH}$ , where  $\text{R}' = \text{monovalent acid radicle}$ . These salts are obtained by the combined action of  $\text{NH}_3$  and air on cobaltous salts; when a stream of air is passed into an ammoniacal solution of a cobaltous salt, the colour of the liquid changes to brown, and if the solution is sufficiently conc. the oxycobaltamine frequently separates; in some cases the salt is obtained by adding a salt or an acid to the solution obtained as described. The oxycobaltamines generally partially decompose when heated alone or in  $\text{NH}_3\text{Aq}$ , giving off oxygen and forming salts of the octamine (*fusco-*) series, which, by combination with  $\text{NH}_3$ , form salts of decamine and dodecamine series. The oxycobaltamines are decomposed by warm water with ppn. of  $\text{Co}_2\text{O}_3.3\text{H}_2\text{O}$  or a basic cobaltous salt and evolution of oxygen. Dilute acids partially decompose the oxycobaltamines of the form  $\text{Co}_2(\text{NH}_3)_6\text{R}'_2\text{O.H.O.OH}$  with production of green salts and separation of water.\* The green salts thus formed are regarded by Vortmann (*M.* 6, 404) as *anhydro-oxycobaltamines*; e.g. oxycobaltamine chloride  $\text{Co}_2(\text{NH}_3)_6\text{Cl}_2\text{O.H.O.OH}$  with conc.  $\text{HClAq}$  gives anhydro-oxycobaltamine chloride  $\text{Co}_2(\text{NH}_3)_6\text{Cl}_2\text{O.OH}$ , thus**

$\text{Co}_2(\text{NH}_3)_6\text{Cl}_2\text{O.H.O.OH} + \text{HCl}$   
 $= \text{Co}_2(\text{NH}_3)_6\text{Cl}_2\text{O.OH} + \text{H}_2\text{O}$ . The oxycobaltamines were formerly represented as containing the group  $\text{Co}_2\text{O}_3$ ; and the anhydro-oxycobaltamines were regarded as acid salts derived from the oxycobaltamines (Maquenne, *C. R.* 96, 344): the change from the chloride to the anhydrochloride, for instance, was formulated thus:—

$\text{Co}_2\text{O}_3(\text{NH}_3)_6\text{Cl}_2\text{H}_2\text{O} + \text{HCl}$   
 $= \text{Co}_2\text{O}_3(\text{NH}_3)_6\text{Cl}_2\text{OH} + \text{H}_2\text{O}$ . But Vortmann's observation that solutions of the oxycobaltamines reduce  $\text{KMnO}_4\text{Aq}$  and  $\text{K}_2\text{Cr}_2\text{O}_7\text{Aq}$  points to the presence of the group  $\text{O.OH}$ ; and the formation of octamine salts with evolution of ammonia and oxygen by heating ammoniacal solutions of oxycobaltamines confirms this supposition; thus

Whether the green salts obtained by the reaction of acids with the oxycobaltamines are regarded as acid salts of the oxycobaltamines (Maquenne), or as anhydro-oxycobaltamines (Vortmann), in either case  $\frac{1}{2}$  of the acid radicle is represented as related to the rest of the salt differently from the other four-fifths; thus the nitrate is either  $\text{Co}_2(\text{NH}_3)_6(\text{NO}_3)_2\text{O.OH}$  or  $\text{Co}_2\text{O}_3(\text{NH}_3)_6(\text{NO}_3)_2\text{H}$ . If Vortmann's formula for the oxycobaltamines is adopted, it is better to regard the green salts as anhydro-oxycobaltamines. One-fifth of the acid radicle is regarded by Vortmann as directly associated with the Co atom. The existence of acid salts of the oxycobaltamines, differing in properties from the anhydro-oxycobaltamines, and very probably belonging to the same type as the oxycobaltamines (e.g.  $\text{Co}_2(\text{NH}_3)_6(\text{NO}_3)_2\text{O.H.O.OH.HNO}_3$ ), tends to show that the green salts are better regarded as anhydro-oxycobaltamines than as acid salts of oxycobaltamines.

**Series I. OXY-COBALTIC SALTS, or AMMONIO-OXYCOBALTIC SALTS,  $\text{Co}_2(\text{NH}_3)_6\text{R}'_2\text{O.H.O.OH}$ .**

#### Oxy-cobaltamine iodide

$\text{Co}_2(\text{NH}_3)_6\text{I}_2\text{O.H.O.OH}$  (Vortmann, *M.* 6, 404); obtained by adding cold conc.  $\text{KI Aq}$  to an oxidised ammoniacal solution of  $\text{CoCl}_2$ . Green needles; unchanged in air; decomposed by much  $\text{H}_2\text{O}$  with evolution of O. Dilute acids separate I and evolve O; hot conc.  $\text{HNO}_3$  forms luteo-cobalt nitrate  $\text{Co}_2(\text{NH}_3)_6(\text{NO}_3)_2$ .

#### Oxy-cobaltamine chloride

$\text{Co}_2(\text{NH}_3)_6\text{Cl}_2\text{O.H.O.OH}$  (Vortmann, *M.* 6, 404); obtained by dissolving crystals of  $\text{CoCl}_2$  in 2½ parts  $\text{NH}_3\text{Aq}$  "S.G. '912, with gentle warming, passing air into the cold solution until the pp. of  $\text{CoCl}_2.x\text{NH}_3$ , which forms, redissolves, saturating with  $\text{NH}_3\text{Cl}$ , and adding alcohol; ppn. is aided by rubbing with a glass rod. Greenish-brown powder; very unstable, easily giving off O, and then passing into fusco-cobalt chloride  $\text{Co}_2(\text{NH}_3)_6\text{Cl}_2(\text{OH})_2$  (cf. Frey, *A. Ch.* [3] 35, 257).

#### Oxy-cobaltamine nitrate

$\text{Co}_2(\text{NH}_3)_6(\text{NO}_3)_2\text{O.H.O.OH}$  (Frey, *l.c.*; Vortmann, *l.c.*; Gibbs, *P. Am. A.* 10 [1875] 1; 11, 1); obtained by leading air into saturated  $\text{Co}_2\text{NO}_3\text{Aq}$ , to which saturated  $\text{NH}_3\text{NO}_3\text{Aq}$ , and 5 parts of  $\text{NH}_3\text{Aq}$  S.G. '938, have been added. Dark brown prismatic crystals. Very unstable; loses water and a little  $\text{NH}_3$  in dry air; when heated appears to form fusco-cobalt nitrate  $\text{Co}_2(\text{NH}_3)_6(\text{NO}_3)_2(\text{OH})_2$ .

#### Oxy-cobaltamine sulphate

$\text{Co}_2(\text{NH}_3)_6(\text{SO}_4)_2\text{O.H.O.OH}$  (Frey; Vortmann); obtained similarly to, but more easily than, the nitrate. Dark brown crystals; more stable than the nitrate; heated to  $110^\circ\text{--}120^\circ$  it loses  $\text{H}_2\text{O}$ ,  $\text{NH}_3$ , and O, and forms fusco-cobalt sulphate  $\text{Co}_2(\text{NH}_3)_6(\text{SO}_4)_2(\text{OH})_2$ .

**Oxy-cobaltamine acid nitrate, sulphate, sulphato-chloride, &c.** These salts are obtained by dissolving the nitrate or sulphate in conc.  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$  respectively, or by dissolving the sulphate or nitrate in conc.  $\text{HClAq}$ . Their compositions are expressed by the formulæ

$\text{Co}_2(\text{NH}_3)_6(\text{NO}_3)_2\text{O.H.O.OH.HNO}_3$ ,  
 $\text{Co}_2(\text{NH}_3)_6(\text{SO}_4)_2\text{O.H.O.OH.2H}_2\text{SO}_4$ ,  
 $\text{Co}_2(\text{NH}_3)_6(\text{SO}_4)_2\text{Cl}_2\text{O.H.O.OH.4HCl}$ ,  
 $\text{Co}_2(\text{NH}_3)_6(\text{NO}_3)_2\text{Cl}_2\text{O.H.O.OH.4HCl}$ ,  
 and  $\text{Co}_2(\text{NH}_3)_6(\text{SO}_4)_2(\text{NO}_3)_2\text{O.H.O.OH.4HNO}_3$ . These salts are all very easily decomposed by heat, giving green salts, the change probably consisting in removal of the excess of acid.

#### Series II. ANHYDRO-OXYCOBALTIC SALTS, or ANHYDRO-OXY-COBALTAMINES,

$\text{Co}_2(\text{NH}_3)_6\text{R}'_2\text{O.OH}$  (Vortmann, *M.* 6, 404).

#### Anhydro-oxy-cobaltamine chloride

$\text{Co}_2(\text{NH}_3)_6\text{Cl}_2\text{O.OH.H}_2\text{O}$ ; obtained by digesting freshly prepared oxy-cobaltamine chloride in cold conc.  $\text{HClAq}$  until the colour is green, and crystallising from warm dilute  $\text{HClAq}$ . Small green needles; stable in air; loses  $\text{NH}_3$  and  $\text{H}_2\text{O}$  on warming; e. sol. water, the solution rapidly decomposes; when a solution in  $\text{HClAq}$  is boiled, purpureo-chloride,  $\text{Co}_2(\text{NH}_3)_6\text{Cl}_2$ , is formed; heated with  $\text{NH}_3\text{Aq}$ , purpureo-chloride is formed, along with luteo-chloride  $\text{Co}_2(\text{NH}_3)_6\text{Cl}_2$ . Forms double salts with  $2\text{Picl}_2.5\text{H}_2\text{O}$ , and  $8\text{HgCl}_2$ .

#### Anhydro-oxy-cobaltamine nitrate

$\text{Co}_2(\text{NH}_3)_6(\text{NO}_3)_2\text{O.OH.H}_2\text{O}$ ; obtained by adding oxy-cobaltamine nitrate to a mixture of equal vols. conc.  $\text{HNO}_3$  and  $\text{H}_2\text{O}$ , digesting in the

cold and then warming until all is dissolved; on cooling a blue-green finely crystalline pp. forms. Sl. sol. water, solution rapidly decomposes; solution in dilute acids may be boiled without change.

The other important salts of the *anhydro-oxy-cobaltamine* series are the following:—

Sulphate  $(\text{Co}_2(\text{NH}_3)_{10} \cdot \text{O.OH})_2(\text{SO}_4)_2 \cdot 8\text{H}_2\text{O}$ .

Dichromate  $(\text{Co}_2(\text{NH}_3)_{10} \cdot \text{O.OH})_2(\text{Cr}_2\text{O}_7)_2 \cdot 8\text{H}_2\text{O}$ .

Chloronitrates

$\text{Co}_2(\text{NH}_3)_{10}(\text{NO}_2)_2\text{Cl}_2 \cdot \text{Cl}_2 \cdot \text{O.OH} \cdot \text{H}_2\text{O}$ , and

$\text{Co}_2(\text{NH}_3)_{10}(\text{NO}_2)_2\text{Cl}_2 \cdot \text{O.OH} \cdot \text{H}_2\text{O}$ .

Acid sulphates

$(\text{Co}_2(\text{NH}_3)_{10} \cdot \text{O.OH})_2(\text{SO}_4)_x \cdot x\text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}$ ;  $x=1$  and 2, and  $n=2$  and 3.

Acid nitrate-sulphate

$\text{Co}_2(\text{NH}_3)_{10}(\text{SO}_4)_x(\text{NO}_3)_{2-x} \cdot \text{O.OH} \cdot \text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$ .

Class III.—COBALTI-AMINES, or AMMONIO-COBALTIC SALTS  $\text{Co}_2(\text{NH}_3)_x\text{R}_4$ ;  $x=6, 8, 10, 12$ . This class comprises by far the greater number of the ammonio-cobalt salts. It is divided into four series, and some of these are again subdivided. The series are:

(i.) *Hexamines*  $\text{Co}_2(\text{NH}_3)_6\text{R}_4$ .

(ii.) *Octamines*  $\text{Co}_2(\text{NH}_3)_8\text{R}_4$ .

(iii.) *Decamines*  $\text{Co}_2(\text{NH}_3)_{10}\text{R}_4$ .

(iv.) *Dodecamines*  $\text{Co}_2(\text{NH}_3)_{12}\text{R}_4$ .

**Series I. HEXAMINES, or HEXAMMONIO-COBALTIC SALTS**  $\text{Co}_2(\text{NH}_3)_6\text{R}_4$ . Also called *dichro-cobaltic salts*. These salts are very unstable; they are readily decomposed by potash.

Hexamine chloride  $\text{Co}_2(\text{NH}_3)_6\text{Cl}_4 \cdot \text{H}_2\text{O}$  (*Dichro-cobaltic-chloride*). Octamine cobalt carbonate,  $\text{Co}_2(\text{NH}_3)_8(\text{CO}_3)_2$ , is obtained by dissolving  $\text{CoCO}_3$  in  $\text{NH}_4\text{Aq}$  in presence of  $(\text{NH}_4)_2\text{CO}_3$ , exposing to air for some time, evaporating on water-bath to a small volume, adding  $(\text{NH}_4)_2\text{CO}_3$ , and evaporating again; this salt is dissolved in  $\text{NH}_4\text{Aq}$ ,  $(\text{NH}_4)_2\text{CO}_3$  is added, and the solution is evaporated to dryness on the water-bath; evaporation after addition of a little water and  $(\text{NH}_4)_2\text{CO}_3$  is repeated two or three times; the crude carbonate thus obtained is treated with dilute  $\text{HClAq}$ ; the turbid liquid is heated nearly to boiling, and then quickly cooled, when the hexamine chloride separates as small green crystals (Vortmann, B. 10, 1451; 15, 1890). Crystallises from neutral solution in green crystals, appearing almost black when large; crystallises from acidified solution in red-brown tables. Dichroism is best seen by evaporating a drop of solution of salt on an object-glass, and examining under microscope. Water is not completely removed at  $120^\circ$ . Fairly soluble in water; on warming solution becomes violet, and contains octamine purpureo-chloride  $\text{Co}_2(\text{NH}_3)_8\text{Cl}_2 \cdot 2\text{H}_2\text{O}$  which may be ppd. by  $\text{HCl}$ ; solution in  $\text{HClAq}$  on warming gives pp. of decamine purpureo-chloride  $\text{Co}_2(\text{NH}_3)_{10}\text{Cl}_2$ . Forms a double salt with  $\text{HgCl}_2$ .

The chief salts of the *hexamine series*, besides the chloride, are the following:—  
 $\text{M} = \text{Co}_2(\text{NH}_3)_6$ .

Basic carbonate  $\text{M}(\text{OH})_2(\text{CO}_3)_2 \cdot 3\text{H}_2\text{O}$ .

Nitrates  $\text{M}(\text{NO}_3)_2 \cdot 8\text{H}_2\text{O}$ ; and

$\text{M}(\text{NO}_3)_2(\text{OH})_2 \cdot 2\text{H}_2\text{O}$ .

Sulphate  $\text{M}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$ .

Nitrate  $\text{M}(\text{NO}_3)_2$  (Erdmann, J. pr. 97, 405).

**Series II. OCTAMINES, or OCTAMMONIO-COBALTIC SALTS**  $\text{Co}_2(\text{NH}_3)_8\text{R}_4$ . The salts of this

series are arranged in three divisions, the *praseo*-, the *rusco*-, and the *roseo-cobaltic salts*.

**Division I. Praseo-cobaltic salts.**

Praseo-cobaltic chloride  $\text{Co}_2(\text{NH}_3)_8\text{Cl}_2 \cdot 2\text{H}_2\text{O}$  (Vortmann, B. 10, 1451; 15, 1890; F. Rose, *Untersuchungen über ammoniakalische Kobaltverbindungen* [Heidelberg, 1871]). This salt exists in two modifications generally known as *praseo-cobaltic chloride* and *octamine-purpureo-cobalt chloride*, respectively. Praseo-chloride forms green lustrous crystals; a. sol. water, the solution readily decomposes, turning violet, and  $\text{HCl}$  then pp. decamine-purpureo-chloride  $\text{Co}_2(\text{NH}_3)_{10}\text{Cl}_2 \cdot 2\text{H}_2\text{O}$ ; dried at  $100^\circ$  this salt becomes anhydrous. Octamine-purpureo-chloride forms deep violet octahedra; does not lose any  $\text{H}_2\text{O}$  at  $120^\circ$ .

The praseo-salt is generally found in the mother-liquor when any cobalt salt is exposed to air in presence of ammonia, and the solution is ppd. by  $\text{HCl}$ ; it is separated from such liquid by addition of  $\text{NH}_4\text{Cl}$ . The pp. is separated from admixed decamine-purpureo-chloride by washing with alcohol, drying, dissolving in conc.  $\text{H}_2\text{SO}_4$ , and carefully ppd. by  $\text{HClAq}$  added drop by drop; it is then dissolved in ice-cold water, and at once ppd. by a little  $\text{HClAq}$ .

The purpureo-salt is obtained by oxidising an ammoniacal cobalt chloride solution in the air, evaporating to a small bulk after addition of  $(\text{NH}_4)_2\text{CO}_3$ , filtering from ppd. luteo-chloride  $(\text{Co}_2(\text{NH}_3)_{12}\text{Cl}_2)$  and allowing to stand.

When a praseo-chloride solution is warmed with fairly dilute  $\text{HClAq}$ , a violet liquid is obtained, from which octamine-purpureo-chloride separates on cooling. When conc.  $\text{H}_2\text{SO}_4$  is added to an aqueous solution of the purpureo-chloride crystals of the praseo-salt gradually separate.

Praseo-chloride forms two double salts with  $\text{HgCl}_2$ , viz.,  $\text{M.HgCl}_2$  and  $\text{M.2HgCl}_2$ . Purpureo-chloride forms the double salts  $\text{M.6HgCl}_2 \cdot 2\text{H}_2\text{O}$  and  $\text{M.3HgCl}_2 \cdot \text{H}_2\text{O}$ ; where  $\text{M} = \text{Co}_2(\text{NH}_3)_8\text{Cl}_2$ . When a solution of octamine carbonate, formed as described under *hexamine chloride* (*v. supra*), is ppd. by cold  $\text{HClAq}$ , small red crystals are obtained; these have the composition  $\text{Co}_2(\text{NH}_3)_8\text{Cl}_2 \cdot 2\text{H}_2\text{O} \cdot 2\text{H}_2\text{O}$ ; at  $120^\circ$  the crystals lose  $2\text{H}_2\text{O}$ , becoming octamine purpureo-chloride. This salt is usually known as octamine roseo-cobalt chloride; it forms a double salt  $\text{Co}_2(\text{NH}_3)_8\text{Cl}_2 \cdot 2\text{H}_2\text{O} \cdot 6\text{HgCl}_2 \cdot 3\text{H}_2\text{O}$ .

The two salts, praseo-cobalt chloride and octamine-purpureo-chloride, are isomeric; in the second the two molecules of water are more firmly held to the rest of the salt than in the praseo-compound. The roseo-chloride differs from the two others by containing two molecules of water loosely held to the rest of the salt. Each of these salts is the representative of a subdivision of praseo-cobaltic salts; the *praseo-salts proper*, the *octamine purpureo-salts*, and the *octamine roseo-salts*. The chief salts in these subdivisions are the following:—  
 $\text{M} = \text{Co}_2(\text{NH}_3)_8$ .

Praseo-cobalt chromate-chloride

$\text{M.Cl}_2 \cdot \text{Cr}_2\text{O}_7 \cdot \text{H}_2\text{O}$ .

Praseo-cobalt nitrate-chloride

$\text{M.Cl}_2(\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$ .

Octamine purpureo-cobalt chromate

$\text{M}(\text{CrO}_4)_2 \cdot 2\text{H}_2\text{O} \cdot 2\text{H}_2\text{O}$ .

Octamine-purpureo-cobalt sulphate  
 $M.(SO_4)_2.2H_2O.2H_2O$ .  
 Octamine roseo-cobalt sulphate  
 $M.(SO_4)_2.2H_2O.4H_2O$ .  
 Octamine cobalt carbonates  $M.(CO_3)_2.3H_2O$ ;  
 and  $M.(CO_3)_2.H_2CO_3.2H_2O$ .  
 Octamine cobalt sulphate-carbonate  
 $M.(CO_3)_2.SO_4.3H_2O$ .  
 Octamine cobalt nitrate  $M.(NO_3)_2.2H_2O$ .

Division II. *Fusco-cobaltic salts*  
 (Fremy, *A. Ch.* [3] 85, 257). These compounds, which are basic salts of the octamine series, are obtained from the brown liquids formed by allowing ammoniacal cobalt solutions to stand for a long time in air; they are also formed by decomposing oxy-cobaltamines by water. They are non-crystallisable; alcohol, or passage of an ammonia-stream, pps. them from their solutions. Boiled with water, especially if alkali is present, they are decomposed with separation of  $Co_2O_3.3H_2O$ . The chief salts are the following:  
 $M = Co_2(NH_3)_4(OH)_2$ .

Fusco-cobalt chloride  $M.Cl_2.2H_2O$ .  
 Fusco-cobalt nitrate  $M.(NO_3)_2.2H_2O$ .  
 Fusco-cobalt sulphate  $M.(SO_4)_2.2H_2O$ .

Division III. *Croceo-cobaltic salts*.  
 These compounds, which are tetra-nitro-derivatives of the praseo-salts, are produced by the action of ammonia and nitrous acid (or ammonium or potassium nitrite) on solution of  $Co_2NO_3$  or  $CoSO_4$ ; dark-coloured solutions are thus formed, from which the croceo-salts separate in yellow crystals mixed with  $Co(OH)_2$ .

Croceo-cobaltic sulphate  
 $Co_2(NH_3)_4(NO_3)_2SO_4$ . Prepared by adding  $NH_4$ Aq and  $(NH_4)_2NO_3$  to  $CoSO_4$ Aq, and recrystallising from hot dilute  $H_2SO_4$ Aq. Yellow lustrous tables; large wine-red crystals from dilute solutions. Sl. sol. hot or cold water. The other important croceo-salts are represented by the following formulae, where  $M = Co_2(NH_3)_4(NO_3)_2$ : Chloride  $M.Cl_2$ ; forms double salts  $M.Cl_2.PtCl_4$  and  $M.Cl_2.2AuCl_3$ ; Bromide  $M.Br_2$ ; Chromate  $M.CrO_4$ ; Dichromate  $M.Cr_2O_7$ ; Nitrate  $M.(NO_3)_2$ ; Periodide  $M.I_2$ .

Series III. DECAMINES, or DECAMMONIO-COBALTIC SALTS,  $Co_2(NH_3)_{10}R_4$ . This series contains very many compounds; these com-

With  $PtCl_4$ , roseo-chloride gives  $M.Cl_2.2PtCl_4.5H_2O$ ; and purpureo-chloride gives  $M.Cl_2.2PtCl_4$ .  
 "  $AnCl_3$  " "  $M.Cl_2.2AnCl_3.2H_2O$ ; " "  $M.Cl_2.2AuCl_3$ .  
 "  $(NH_4)_2C_2O_4$  " "  $M.(C_2O_4)_2.6H_2O$ ; " "  $M.Cl_2(C_2O_4)_2$ .  
 $M = Co_2(NH_3)_{10}$ .

pounds are well-marked and stable bodies, frequently obtained from cobaltamines by decomposing these by acids. The series is arranged in three divisions: the roseo-, the purpureo-, and the xantho-salts. The following are typical representatives of these divisions: roseo-cobaltic chloride  $Co_2(NH_3)_{10}Cl_2(H_2O)_2$ ; purpureo-cobaltic chloride  $Co_2(NH_3)_{10}Cl_2$ ; xantho-cobaltic chloride  $Co_2(NH_3)_{10}(NO_3)_2Cl_2$ . The roseo- and purpureo-salts differ in the quantities of water they contain, the purpureo-salts are generally anhydrous, the roseo-salts usually contain  $2H_2O$ ; inasmuch as these salts form very distinct compounds with different properties, it seems necessary to conclude that the  $2H_2O$  of the roseo-salts is not water of crystallisation, but forms an integral part of the molecule of each of these salts. The purpureo-salts are less soluble in water than

the roseo-salts; they are changed to the latter by long-continued warming in presence of water, by long-continued digestion with dilute acids at the ordinary temperature, or generally by processes which result in hydration, but not merely by solution in water and crystallisation. The xantho-salts bear a somewhat similar relation to the purpureo-salts that the croceo-compounds of the same series; the xantho-salts are dinitro-derivatives of the purpureo-salts, the croceo-salts are tetra-nitro-derivatives of the praseo-salts.

Division I. *Roseo-cobaltic salts*. These salts are obtained as products of the decomposition of the oxy-cobaltamines, from aqueous solutions of which they are ppd. by acids in the cold. They are obtained from purpureo-salts by long-continued digestion with dilute acids, or, more readily, by treating these salts with alkalis, e.g. dilute solution of  $NH_3$ , or  $NaOH$ ,  $Ag_2O$  and water, or  $BaCO_3$ —and subsequent saturation with acids. The roseo-salts form red to peach-coloured crystals, which exhibit dichroism; they are fairly easily soluble in water; their ammoniacal solutions are decomposed on boiling with ppn. of  $Co_2O_3.3H_2O$ . These salts lose water by treatment with conc. acids, and form purpureo-salts. Roseo-salts in solution give a pp. of roseo-pyrophosphate on addition of sodium pyrophosphate; potassium ferrocyanide also gives a pp. with these salts; these reactions serve to distinguish roseo- from purpureo-salts (Jørgensen, *J. pr.* [2] 81, 49). The roseo-salts show many analogies—e.g. in crystalline form, methods of formation, and general reactions—with the dodecammonio- (o-luteo-) salts  $Co_2(NH_3)_{12}R_4$ . Jørgensen (*J. pr.* [2] 81, 49) regards the roseo-decamines as luteo salts in which  $2NH_3$  is replaced by  $2H_2O$ . Roseo chloride, nitrate, oxalate, &c., in aqueous solution react with  $BaCl_2$ Aq and  $Ba(NO_3)_2$ Aq to give only roseo-salts. Roseo-chloride is soluble in 4.8 pt water at  $10^\circ$ , while purpureo-chloride requires 287 pts. water for solution at  $10^\circ$ . Aqueous solutions of the two chlorides often give different compounds by reacting with the same reagent e.g.:

Roseo-cobaltic chloride  $Co_2(NH_3)_{10}(H_2O)_2$  (Jørgensen, *J. pr.* [2] 18, 209; 31, 49; Gibbs, *Genth, Researches on the Ammonia-cobalt bas* [Washington, 1856]; Mills, *P. M.* [4] 85, 24; Geuther, *Lehrbuch der Chemie*, 442). Obtain from an ammoniacal solution of  $CoCl_2$  by oxidising in air, or by  $KMnO_4$ Aq (Mills), and p. by  $HCl$ , avoiding rise of temperature; also digesting purpureo-chloride (*q. v.*) with dil.  $HCl$ Aq, or by dissolving the same salt in  $NH_3$  and ppg. by  $HCl$  in the cold (Jørgensen, *l. c.*; Geuther, *l. c.*). A red, dichroic powder, appears crystalline under the microscope. Loses  $2H_2O$  at  $100^\circ$ , giving purpureo-chloride. Soluble 4.8 pts. water at  $10^\circ$ . Very unstable, easily goes to purpureo-chloride. Forms a gold salt,  $M.2Au$  by reaction with  $AnCl_3$ ,  $NaCl$ : forms three  $Pt$  sal  $M.PtCl_4.2H_2O$ ,  $M.2PtCl_4.H_2O$ , and  $M.3PtCl_4.6H_2O$ .

(Jørgensen, *l.c.*): forms two Hg salts;  $M.2HgCl_2$  and  $M.6HgCl_2.2H_2O$  (Jørgensen, *l.c.*).  
 $[M = Co_2(NH_3)_{10}(OH)_2]Cl_2$

Gibbs (*l.c.*) describes a yellow form of roseo-chloride obtained by decomposing the yellow form of roseo-sulphate (*q. v.*) by  $BaCl_2$  aq; this form does not yield purpureo-chloride by reaction with  $HCl$  aq.

#### Roseo-cobaltic sulphate

$Co_2(NH_3)_{10}(H_2O)_2(SO_4)_2.3H_2O$  (Fremy, *A. Ch.* [3] 35, 257; Gibbs a. Genth, *Researches on the Ammonia-cobalt bases*, [Washington, 1856]; Gibbs, *P. Am. A.* 10, 1; 11, 1; Braun, *A.* 138, 109; 142, 50; Jørgensen, *J. pr.* [2] 31, 49; 35, 417). Obtained by adding the proper quantity of  $H_2SO_4$  aq to a solution of roseo-carbonate, and evaporating over  $H_2SO_4$  or ppg. by alcohol; the roseo-carbonate solution is prepared by decomposing purpureo-chloride or bromide by  $Ag_2CO_3$  (Genth, *A.* 80, 275; Claudet, *P. M.* [4] 2, 253; Jørgensen, *J. pr.* [2] 18, 209; 19, 49). Roseo-sulphate forms reddish crystals; soluble in 916 pts. water at  $17^\circ$ , and in 58 pts. water at  $27^\circ$ . Two other forms of the sulphate are described by Gibbs a. Genth (*P. Am. A.* 10, 1; 11, 1); they differ chiefly in solubility from the ordinary form. An acid roseo-sulphate  $Co_2(NH_3)_{10}(OH)_2(SO_4)_2.2H_2SO_4.H_2O$  is described by Fremy (*l.c.*) (v. also Jørgensen, *l.c.*). The normal sulphate forms a gold and also a Pt salt:  $M.(SO_4)_2.2AuCl_3$  and  $M.(SO_4)_2.Cl_2.PtCl_3$  (Jørgensen, *l.c.*) [ $M = Co_2(NH_3)_{10}(OH)_2$ ].

The chief salts of the roseo- division besides the chloride and sulphate are represented by the following formulae, where  $M = Co_2(NH_3)_{10}(H_2O)_2$ :—  
*Dichromate*,  $M.(Cr_2O_7)_2.8H_2O$  (Gibbs). *Bromide*,  $M.Br_2$ , forming Pt salts with  $2PtBr_2.2H_2O$ , and  $3PtBr_2.4H_2O$  (Jørgensen). *Iodide*,  $M.I_2$  (Jørgensen). *Nitrate*,  $M.(NO_3)_2$  (Gibbs; Jørgensen); forming a Pt salt,  $M.(NO_3)_2.Cl_2.2PtCl_2.2H_2O$ . *Nitrate-sulphate*,  $M.(NO_3)_2(SO_4)_2$  (J.). *Oxalate*,  $M.(C_2O_4)_2.4H_2O$ . *Sulphato-oxalate*,  $M.(C_2O_4)_2(SO_4)_2.2H_2O$  (Gibbs a. Genth). *Orthophosphates*,  $M.(PO_4)_2.H_2PO_4.4H_2O$ ;  $M.(OH)_2(PO_4)_2.2H_2O$  (J.). *Pyrophosphates*,  $M_2.(P_2O_5)_2.12H_2O$ ;  $M.(P_2O_5)_2$  (J.); also  $M_2.(P_2O_5)_2.28H_2O$  (Gibbs, Braun, Porumbaru, *C. R.* 91, 933; 93, 342). *Bromo-sulphate*,  $M.Br_2(SO_4)_2$ ; forms a gold salt  $M.Br_2(SO_4)_2.2AuBr_3$  (J.). *Iodosulphate*,  $M.I_2(SO_4)_2$  (Krok, *Acta Univers. Lund.* 1870). *Sulphite*,  $M.(SO_3)_2.3H_2O$  (Gibbs); forming a double salt  $M.(SO_3)_2.Co_2(SO_3)_2.9H_2O$  (Künzel, *J. pr.* 72, 209; Geuther, *l.c.*).

**Division II. Purpureo-cobaltic salts.**  $Co_2(NH_3)_{10}R_2$ . These salts are the most stable of all the cobaltamines. They are formed from the roseo-salts by heating with conc. acids, or sometimes by continued digestion with conc. acids in the cold; also by the action of acids on fusco- and xantho-cobaltic salts. The purpureo-salts are generally anhydrous; they are less soluble in water than the roseo-salts, into which salts they are changed by prolonged digestion with dilute acids. Solutions of purpureo-salts are decomposed by boiling with alkalis, giving pps. of  $Co_2O_3.3H_2O$ . These salts probably contain two acidic radicles more closely associated with the rest of the salt than the other four radicles; e.g. they form xantho-salts  $Co_2(NH_3)_{10}(NO_3)_2.R_2$ ; again, chloro-purpureo-sulphate  $Co_2(NH_3)_{10}Cl_2(SO_4)_2$ , does not give  $HCl$

with conc.  $H_2SO_4$ , nor is it pptd. by  $AgNO_3$  aq even on warming (Jørgensen). It is convenient to consider the purpureo-salts in four main sections: the chloro-purpureo-salts  $Co_2(NH_3)_{10}Cl_2.R_2$ , the bromo-purpureo-salts  $Co_2(NH_3)_{10}Br_2.R_2$ , the nitrate-purpureo-salts  $Co_2(NH_3)_{10}(NO_3)_2.R_2$ , and the sulphato-purpureo-salts  $Co_2(NH_3)_{10}(SO_4)_2.R_2$ .

#### Chloro-purpureo-cobaltic chloride

$Co_2(NH_3)_{10}Cl_2.Cl_2$  (Mills, *P. M.* [4] 35, 245; Porumbaru, *C. R.* 91, 933; 93, 342; Genth, *A.* 80, 275; Claudet, *P. M.* [4] 2, 253; Terrell, *C. R.* 62, 139; Braun, *A.* 138, 109; 142, 50). This salt is formed when an ammoniacal solution of  $CoCl_2$  is allowed to oxidise in the air; boiling with excess of  $HCl$  aq pps. the salt as a carmine-red powder. The reaction of  $HCl$  aq or  $NH_4Cl$  aq with very many cobaltamines produces this salt. Instead of oxidising  $CoCl_2$  in  $NH_4$  aq in air, which process takes a long time to accomplish, it is advisable to use  $KMnO_4$  aq (Terrell), bleaching powder (Mills), or ozonised turpentine or indigo-blue (Braun). Chloro-purpureo-chloride is a carmine-red crystalline powder; in larger crystals it appears carmine-red to black; these crystals are tetragonal pyramids, isomorphous with roseo-chloride; they are dichroic; S.G.  $2.3$  1.802; sol. 287 pts. water at  $10^\circ$ , 255 pts. at  $11^\circ$ , and 244 pts. at  $15^\circ$  (F. Rose); insol. alcohol according to Fremy (*A. Ch.* [3] 35, 257). An aqueous or alkaline, but not an acid, solution, pps.  $Co_2O_3.3H_2O$  on boiling. Heated in air  $CoCl_2$  and  $Co$  are obtained; at a higher temperature with free access of air  $Co_3O_4$  is produced. Many double salts of chloro-purpureo-chloride are known, e.g.  $M.Cl_2.2PtCl_2$ ;  $M.Cl_2.2AuCl_3$ ;  $M.Cl_2.6HgCl_2$ ;  $M(SiF_6)_2$  [ $M = Co_2(NH_3)_{10}Cl_2$ ].

The other chief salts of the chloro-purpureo-section of purpureo-cobaltic salts are the following:—

*Bromide*,  $M.Br_2$ ; double salts,  $M.Br_2.2PtBr_2$ , ( $M.Br_2$ ),  $9HgBr_2$ .

*Iodide*,  $M.I_2$ ; double salts,  $M.I_2.4HgI_2$ ,  $M.I_2.2HgI_2$ .

*Carbonates*,  $M.(CO_3)_2.9H_2O$ ;  $M.(CO_3)_2.H_2O$ .

*Chromate*,  $M.(CrO_4)_2$  (Jørgensen, *J. pr.* [2] 18, 209).

*Dichromate*,  $M.(Cr_2O_7)_2$  (Jørgensen).

*Nitrate*,  $M.(NO_3)_2$  (J.).

*Oxalate*,  $M.(C_2O_4)_2$  (J.).

*Pyrophosphates*,  $M.(P_2O_5)_2.xH_2O$ ;

$M.(P_2O_5)_2.H_2P_2O_7$  (J.); double salts,

$M.(2PO_4.H_5MoO_4)_2$ ,  $M.(2PO_4.H_5MoO_4)_2$  (J.).

*Sulphates*,  $M.(SO_4)_2.4H_2O$ ;  $M.(SO_4)_2$ ;

$M_r.(SO_4)_2.(HSO_4)_2$  (J.).

*Dithionate*,  $M.(S_2O_6)_2$  (J.).

*Thiosulphate*,  $M.(S_2O_3)_2$  (J.).

*Tartrate*,  $M.(C_4H_4O_6)_2.5H_2O$  (J.).

#### Bromo-purpureo-cobaltic bromide

$Co_2(NH_3)_{10}Br_2.Br_2$  (Jørgensen, *J. pr.* [2] 19, 49). Obtained by oxidising ammoniacal  $CoBr_2$  aq and heating with  $HBr$  aq; or by heating roseo-sulphate with conc.  $HBr$  aq, and in other ways. Blue-violet, dichroic, microscopic octahedra; from solutions in very dilute  $HBr$  aq separates as large black octahedra. S.G.  $\bar{V} = 2.488$ . Less sol. water than the chloride; 1 pt. dissolves in 530 water at  $16^\circ$ ; insol.  $HBr$  aq,  $KBr$  aq, and alcohol, but al. sol. in warm water acidulated with  $HBr$ , long digestion with this liquid pro-

duces roseo-bromide; decomposed to bromo-purpureo-chloride by digestion with excess of  $\text{AgCl}$ ;  $\text{Ag}_2\text{O}$  or  $\text{Ag}_2\text{CO}_3$  produces solutions of roseo-hydroxide and carbonate respectively. Forms double salts, e.g.  $\text{M.Br.}6\text{HgBr}_2$ ;  $\text{M.}(\text{SiF}_6)_2$ ;  $\text{M.Br.}2\text{PtBr}$ , ( $\text{M} = \text{Co}_2(\text{NH}_3)_{10}\text{Br}_2$ ).

The following are the chief salts of the bromo-purpureo- section of purpureo-cobaltic compounds:

*Chloride*,  $\text{M.Cl.}$ ; double salts,  $\text{M.Cl.}2\text{PtCl.}$ ,  $\text{M.Cl.}6\text{HgCl}_2$  (J.).

*Chromate*,  $\text{M.}(\text{CrO}_4)_2$  (J.).

*Nitrate*,  $\text{M.}(\text{NO}_3)_4$  (J.).

*Oxalate*,  $\text{M.}(\text{C}_2\text{O}_4)_2$  (J.).

*Sulphate*,  $\text{M.}(\text{SO}_4)_2$  (J.).

*Dithionate*,  $\text{M.}(\text{S}_2\text{O}_6)_2$  (J.).

*Nitrate-purpureo-cobaltic nitrate*

$\text{Co}_2(\text{NH}_3)_{10}(\text{NO}_3)_2(\text{NO}_3)_2$  (Genth, A. 80, 275; Frey, A. Ch. [3] 35, 267; Gibbs, *Researches*, &c.; also P. Am. A. 10, 1; 11, 1). Obtained by dissolving  $\text{CoCO}_3$  in the minimum of warm dilute  $\text{HNO}_3\text{Aq}$ , adding twice the volume of conc.  $\text{NH}_3\text{Aq}$ , boiling with addition of 127 pts. I for every 59 pts. Co used, filtering after I is all dissolved (from ppd. luteo-salt), and warming the filtrate with  $\text{HNO}_3\text{Aq}$ , whereby I is changed to  $\text{HIO}$ , and the nitrate-salt separates out (Jørgensen, J. pr. [2] 23, 227). Red powder with shade of violet; 1 pt. dissolves in 273 pts. water at  $16^\circ$ ; decomposed by boiling with water, giving  $\text{Co}_2\text{O}_3.3\text{H}_2\text{O}$ . The nitrate-salts are more easily changed by hot water to roseo-salts than are the chloro- and bromo-purpureo salts. *Basic nitrates* are known;  $\text{Co}_2(\text{NH}_3)_{10}(\text{OH})_2(\text{NO}_3)_2.6\text{H}_2\text{O}$  (Gibbs); and  $\text{Co}_2(\text{NH}_3)_{10}(\text{OH})(\text{NO}_3)_2$  (Künzel, J. pr. 72, 209).

The following nitrate-compounds form the more important members of the section:

*Chloride*,  $\text{M.Cl.}$ ; double salts,  $\text{M.Cl.}2\text{PtCl.}$ ,  $\text{M.Cl.}2\text{HgCl}_2$  (J.).

*Bromide*,  $\text{M.Br.}$  (J.).

*Chromate*,  $\text{M.}(\text{CrO}_4)_2$ .

*Dichromate*,  $\text{M.}(\text{Cr}_2\text{O}_7)_2.2\text{H}_2\text{O}$  (J.).

*Oxalate*,  $\text{M.}(\text{C}_2\text{O}_4)_2$  (J.).

*Sulphate*,  $\text{M.}(\text{SO}_4)_2.2\text{H}_2\text{O}$  (J.).

*Dithionate*,  $\text{M.}(\text{S}_2\text{O}_6)_2.2\text{H}_2\text{O}$  (J.).

*Diamine-cobalt nitrite*  $\text{M.}2[\text{Co}_2(\text{NH}_3)_4(\text{NO}_2)_2]$  (J.).

*Sulphato-purpureo-cobaltic sulphate*

$\text{Co}_2(\text{NH}_3)_{10}(\text{SO}_4)_2(\text{SO}_4)_2.2\text{H}_2\text{O}$  (Gibbs, P. Am. A. 10, 1; 11, 1; Jørgensen, J. pr. [2] 31, 262). Obtained by adding alcohol to an oxidised ammoniacal solution of  $\text{CoSO}_4$  (Gibbs), or to a  $2\frac{1}{2}$  p.c. aqueous solution of the acid sulphate  $\text{Co}_2(\text{NH}_3)_{10}(\text{SO}_4)_2(\text{SO}_4)_2.4\text{H}_2\text{O}$  (J.). Violet-red, microscopic, dichroic needles; v. sol. water, from which solution roseo-sulphate separates on evaporation. Forms a Pt salt,  $\text{Co}_2(\text{NH}_3)_{10}(\text{SO}_4)_2\text{SO}_4\text{PtCl}_2.2\text{H}_2\text{O}$ . The chief sulphato-salts are the following:

*Bromide*,  $\text{M.}(\text{SO}_4)_2\text{Br}_2$  (J.).

*Nitrate*,  $\text{M.}(\text{SO}_4)_2(\text{NO}_3)_2$  (J.).

A few other purpureo-cobaltic salts are known besides those belonging to the four sections already described; the chief are

*Purpureo-cobaltic iodide*,

$\text{Co}_2(\text{NH}_3)_{10}\text{I}_2$  (J., J. pr. [3] 31, 262).

*Purpureo-cobaltic chromate* and di-

*chromate*,  $\text{Co}_2(\text{NH}_3)_{10}(\text{OH})_2(\text{CrO}_4)_2$ ,  $\text{Co}_2(\text{NH}_3)_{10}(\text{Cr}_2\text{O}_7)_2.2\text{H}_2\text{O}$  (Gibbs).

#### Division III. Xantho-cobaltic salts.

These salts are derived from the purpureo-compounds by replacing one-third of the acidic radicals by the group  $\text{NO}_2$ ; they may be called *nitro-purpureo-salts*,  $\text{Co}_2(\text{NH}_3)_{10}\text{R}_2(\text{NO}_2)_2$ . These salts are produced by the action of nitrous acid or nitrites on ammoniacal solutions of cobaltous salts, or on neutral or acid solutions of purpureo- or roseo-cobaltic salts. The xantho-salts are yellow or brownish yellow; they are more soluble in water, and more easily decomposed by water, than the other salts of the decamine series. By reacting with mineral acids they form purpureo-salts. The following are the chief xantho-salts:—

(Gibbs & Genth, *Researches on the Ammonia-cobalt bases* (Washington, 1856)).

*Chloride*,  $\text{M.Cl.}$ ; double salts,

$\text{M.Cl.}2\text{AuCl.}2\text{H}_2\text{O}$ ;  $\text{M.Cl.}2\text{PtCl.}2\text{H}_2\text{O}$ ;

$\text{M.Cl.}4\text{HgCl.}2\text{H}_2\text{O}$ .

*Iodide*,  $\text{M.I.}$ .

*Chromate*,  $\text{M.}(\text{CrO}_4)_2.2\text{H}_2\text{O}$ .

*Dichromate*,  $\text{M.}(\text{Cr}_2\text{O}_7)_2$ .

*Oxalate*,  $\text{M.}(\text{C}_2\text{O}_4)_2$ .

*Sulphate*,  $\text{M.}(\text{SO}_4)_2$ .

*Iodo-sulphate*,  $\text{M.I.}(\text{SO}_4)_2$ .

*Nitrate*,  $\text{M.}(\text{NO}_3)_2$ .

*Chloro-nitrate*,  $\text{M.Cl.}(\text{NO}_3)_2$ ; double salts,  $\text{M.Cl.}(\text{NO}_3)_2.2\text{AuCl.}$ ;  $\text{M.Cl.}(\text{NO}_3)_2.\text{PtCl.}$

*Bromo-nitrate*,  $\text{M.Br.}(\text{NO}_3)_2$ .

*Nitrite*,  $\text{M.}(\text{NO}_2)_2.4\text{H}_2\text{O}$ ; double salt,  $\text{M.}(\text{NO}_2)_2.2(\text{Co.}(\text{NO}_2)_2)$ .

#### Series IV. DODECAMINES, or DODECAMONTO-COBALTIC SALTS, or LUTEO-COBALTIC SALTS,

$\text{Co}_2(\text{NH}_3)_{12}\text{R}_2$ . These salts are formed, along with other cobaltamines, by the oxidation of ammoniacal solutions of cobaltous compounds, especially in presence of much salammmoniac; they are also produced by treating fusco-cobaltic salts with dilute acids, and by boiling roseo- or purpureo-cobaltic salts with ammonia. The luteo-salts are yellow to bronze-yellow in colour; easily crystallisable; generally more soluble in water than the corresponding roseo-salts. Acid solutions of these salts are stable; aqueous and alkaline solutions are decomposed on boiling with ppn. of  $\text{Co}_2\text{O}_3.3\text{H}_2\text{O}$ . Those luteo-salts which contain water of crystallisation effloresce in air or over  $\text{H}_2\text{SO}_4$  in *vacuo*. The luteo-salts are closely analogous to the roseo-salts of the decamine series,  $\text{Co}_2(\text{NH}_3)_{10}(\text{OH})_2\text{R}_2$ ; the crystalline forms of many luteo- and roseo-salts are the same; the solubilities are similar; both series of salts give similar pps. with  $\text{K.Fe}(\text{CN})_6\text{Aq}$  and  $\text{Na}_2\text{P}_2\text{O}_7\text{Aq}$ ; haloid salts of both series are decomposed by Ag salts giving up the whole of their halogen. Ammonia reacts differently with the two series; the roseo-salts are dissolved with formation of basic compounds, while the luteo-salts are unchanged. Jørgensen (J. pr. [2] 31, 49) regards the luteo-salts as roseo-compounds in which  $2\text{H}_2\text{O}$  has been replaced by  $2\text{NH}_3$ .

Luteo-cobaltic chloride  $\text{Co}_2(\text{NH}_3)_{12}\text{Cl}_2$  (Mills, P. M. [4] 35, 245; Genth, A. 80, 275; Braun, A. 138, 109; 142, 50; Jørgensen, J. pr. [2] 35, 417). Obtained by heating an ammoniacal solution of  $\text{CoCl}_2$  in presence of  $\text{NH}_4\text{Cl}$  and an

oxidiser such as  $\text{PbO}_2$ ,  $\text{MnO}_2$ , or  $\text{KMnO}_4$ ; also by digesting purpureo-chloride with  $\text{NH}_4\text{Aq}$  to  $50^\circ\text{--}60^\circ$  in a closed tube, and in other ways. Red-yellow, dichroic, monoclinic crystals; S.G. 1.7016 at  $20^\circ$ ; when dry it is unchanged in air at  $180^\circ$ ; soluble in 16.8 parts water at  $11.4^\circ$  (F. Rose); crystallises from hot water on cooling; aqueous solution is ppd. by alkali chlorides, mineral acids and alcohol; unchanged by heating with conc.  $\text{HClAq}$  at  $100^\circ$  in a closed tube; slowly decomposed by heating with  $\text{NH}_4\text{Aq}$ , more rapidly by  $\text{KOH Aq}$ . Forms various double salts of which the chief are:— $\text{M.2AuCl}_3$  (Jørgensen),  $\text{M.2PtCl}_2 \cdot \text{H}_2\text{O}$ ,  $\text{M.PtCl}_2 \cdot 2\text{H}_2\text{O}$ ,  $\text{M.3PtCl}_2 \cdot 6\text{H}_2\text{O}$ ,  $\text{M.3PtCl}_2 \cdot 4\text{H}_2\text{O}$ ,  $\text{M.2HgCl}_2$ ,  $\text{M.6HgCl}_2 \cdot 2\text{H}_2\text{O}$ ,  $\text{M.3SnCl}_2 \cdot 10\text{H}_2\text{O}$  (J.; also Braun) [ $\text{M} = \text{Co}_2(\text{NH}_4)_2\text{Cl}_2$ ].

#### Luteo-cobaltic sulphate

$\text{Co}_2(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$ . Obtained by passing air for some days into an ammoniacal solution of  $\text{CoSO}_4$  and  $\text{CoCl}_2$  mixed with  $\text{NH}_4\text{Cl}$ , treating the yellow pp. of luteo-chloride and sulphate which forms with hot water, adding  $\text{Ag}_2\text{SO}_4$  and a few drops of  $\text{H}_2\text{SO}_4\text{Aq}$  to the solution, and crystallising by evaporation (Gibbs a. Genth, *Researches*, &c.). Also by rubbing together luteo-chloride and  $\text{Ag}_2\text{O}$  with water, filtering, acidulating the filtrate with  $\text{H}_2\text{SO}_4$ , and evaporating (Jørgensen, *J. pr.* [2] 35, 417). Yellow, rhombic, dichroic, crystals; slightly soluble in cold, more soluble in hot water; loses  $4\text{H}_2\text{O}$  over  $\text{H}_2\text{SO}_4$ ; aqueous solution is only slowly decomposed on boiling; not ppd. by acids from aqueous solution. Forms double salts with sulphates of Co and La;  $\text{M.3LaSO}_4 \cdot \text{H}_2\text{O}$ ,  $\text{M.3CeSO}_4 \cdot \text{H}_2\text{O}$ ,  $\text{M.Ce}(\text{SO}_4)_2 \cdot \text{H}_2\text{O}$  (Wing, *Am. S.* 49, 363). [ $\text{M} = \text{Co}_2(\text{NH}_4)_2(\text{SO}_4)_2$ ].

The chief luteo-salts besides the chloride and sulphate are the following:— $\text{M} = \text{Co}_2(\text{NH}_4)_2$ .

Carbonate,  $\text{M.}(\text{CO}_3)_2 \cdot 7\text{H}_2\text{O}$  (Gibbs a. Genth, *Researches*, &c.).

Chromate,  $\text{M.}(\text{CrO}_4)_2 \cdot 5\text{H}_2\text{O}$  (G. a. G.).

Dichromate,  $\text{M.}(\text{Cr}_2\text{O}_7)_2 \cdot x\text{H}_2\text{O}$ .

Bromide,  $\text{M.Br}_2$ ; double salt,

$\text{M.Br}_2 \cdot 2\text{PtBr}_2 \cdot 2\text{H}_2\text{O}$  (Jørgensen).

Iodide,  $\text{M.I}_2$  (J.; G. a. G.).

Nitrate,  $\text{M.}(\text{NO}_3)_2$ ; double salt,

$\text{M.}(\text{NO}_3)_2 \cdot \text{Cl}_2 \cdot 2\text{PtCl}_2 \cdot 2\text{H}_2\text{O}$  (J.; also Fremy, *A. Ch.* [3] 85, 257).

Nitrato-sulphate,  $\text{M.}(\text{NO}_3)_2(\text{SO}_4)_2$  (J.).

Oxalate,  $\text{M.}(\text{C}_2\text{O}_4)_2 \cdot 4\text{H}_2\text{O}$ ; double salt,  $\text{M.}(\text{C}_2\text{O}_4)_2 \cdot \text{Cl}_2 \cdot 2\text{AuCl}_3 \cdot 4\text{H}_2\text{O}$  (G. a. G.).

Phosphates,  $\text{M.}(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$  (J.);  $\text{M.}(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$  (J.);  $\text{M.}(\text{P}_2\text{O}_7)_2 \cdot 23\text{H}_2\text{O}$  (J.);  $\text{M.}(\text{P}_2\text{O}_7)_2 \cdot 20\text{H}_2\text{O}$ ;  $\text{M.}(\text{P}_2\text{O}_7)_2 \cdot 2\text{H}_2\text{O}$  (J.).

Chloro-sulphate,  $\text{M.}(\text{SO}_4)_2 \cdot \text{Cl}_2$ ; double salts,  $\text{M.}(\text{SO}_4)_2 \cdot \text{Cl}_2 \cdot 2\text{AuCl}_3$ ,  $\text{M.}(\text{SO}_4)_2 \cdot \text{Cl}_2 \cdot 2\text{HgCl}_2$  (J.; G. a. G. & Schiff, *A.* 123, 1; 121, 124; Krok, *Acta Univ. Lund*, 1870).

Bromo-sulphate,  $\text{M.}(\text{SO}_4)_2 \cdot \text{Br}_2$  (J.); double salt,  $\text{M.}(\text{SO}_4)_2 \cdot \text{Br}_2 \cdot 2\text{AuCl}_3$ .

Iodo-sulphate,  $\text{M.}(\text{SO}_4)_2 \cdot \text{I}_2$  (Krok).

Double salts of nitrate, sulphite, and dithionate,  $\text{M.}(\text{NO}_3)_2 \cdot \text{Co}_2(\text{NO}_3)_2$  (Sadler, *Am. S.* 49, 198);  $\text{M.}(\text{SO}_3)_2 \cdot \text{Co}_2(\text{SO}_3)_2 \cdot 2\text{H}_2\text{O}$  (Geuther, *A.* 128, 155; Künzel, *J. pr.* 72, 209);  $\text{M.}(\text{SO}_3)_2 \cdot 2\text{Co}_2(\text{SO}_3)_2 \cdot 16\text{H}_2\text{O}$  (Geuther, Künzel);  $2[\text{M.}(\text{S}_2\text{O}_8)_2 \cdot (\text{OH})_2] \cdot \text{Co}_2(\text{S}_2\text{O}_8)_2 \cdot (\text{OH})_2$  (G.; also K.).

#### COBALTAMINES NOT INCLUDED IN ANY OF THE FOREGOING CLASSES.

Erdmann's salt  $\text{Co}_2(\text{NH}_4)_2(\text{NO}_3)_2 \cdot \text{K}_2$  (Erdmann, *J. pr.* 97, 405). Brown, lustrous, prisms, separating from a solution of  $\text{CoCl}_2$  in presence of much  $\text{NH}_4\text{Cl}$  on addition of  $\text{KNO}_3$ . Solutions of this salt give pps. of analogous compositions with solutions of many metallic salts, e.g. of Pb, Hg, Ag, Ti (Gibbs, *P. Am. A.* 10, 1; 11, 1).

#### Melano-cobaltic chloride

$\text{Co}_2(\text{NH}_4)_2 \cdot \text{NH}_4\text{Cl} \cdot \text{Cl}_2$  (F. Rose; Vortmann, *B.* 10, 1451; 15, 1890). Greyish violet, very hygroscopic, crystals; obtained by oxidising an ammoniacal solution of a cobaltous salt, adding  $\text{HClAq}$ , filtering after an hour or so from purpureo-chloride, and dropping the filtrate into an equal volume of ice-cold fuming  $\text{HClAq}$ . This compound forms double salts, and derivatives, especially  $\text{M.Cl}_2 \cdot \text{PtCl}_2$ ,  $\text{M.}(\text{OH})_2 \cdot \text{Cl}_2 \cdot \text{PtCl}_2$ ,  $\text{M.}(\text{OH})_2 \cdot \text{Cl}_2 \cdot 3\text{HgCl}_2 \cdot \text{H}_2\text{O}$  (Vortmann). [ $\text{M} = \text{Co}_2(\text{NH}_4)_2 \cdot \text{NH}_4\text{Cl}_2$ ].

#### Ammonio-cobaltic oxychloride

$\text{Co}_2(\text{NH}_4)_2 \cdot \text{O} \cdot \text{Cl}_2 \cdot 5\text{H}_2\text{O}$  (Fremy, *A. Ch.* [3] 85, 257). Black crystals; obtained by exposing ammoniacal  $\text{CoCl}_2\text{Aq}$  to the air for some months, boiling with  $\text{NH}_4\text{Aq}$ , filtering from purpureo-chloride, and boiling again. M. M. P. M.

COBALTATES. When  $\text{CoO}$ ,  $\text{Co}(\text{OH})_2$ , or  $\text{CoCO}_3$  is dropped into 6–8 parts molten potash, a blue colour is formed which after a time changes to brown; if fusion is continued until dark-coloured crystals begin to form, the mass is then allowed to cool and treated with water, thin, black, lustrous, six-sided tablets remain. These crystals have the composition  $(\text{Co}_2\text{O}_3)_x \cdot \text{K}_2\text{O} \cdot x\text{H}_2\text{O}$ ; according to Schwarzenberg  $x=3$ , or if the crystals are dried at  $200^\circ$   $x=1$  (*A.* 97, 212; also Mayer, *A.* 101, 268). Von Pebal (*A.* 100, 257) says that all water is removed at  $100^\circ$ . The crystals of potassium cobaltate are insoluble in water; they are decomposed at a little over  $200^\circ$ ; water then dissolves out  $\text{K}_2\text{O}$  and  $\text{Co}_2\text{O}_3$  remains. Mayer (*L.c.*) says that long-continued washing or boiling with water removes potash from the original crystals, and that dilute  $\text{HClAq}$  removes Co (cf. also Russell, *Pr.* 32, 258). M. M. P. M.

#### COBALTI-CYANIDES and COBALTO-CYANIDES v. CYANIDES.

COBALT COLOURING MATTERS. Addition of a Co salt to potash glass produces a deep blue colour. Roasted Co ore is fused with pearl-ash and quartz-sand, the molten mass is poured into water, and then finely powdered; it is used as a colouring matter under the name of *Smalt*. Smalt is essentially a double silicate of Co and K approaching the composition  $\text{CoO} \cdot \text{K}_2\text{O} \cdot (\text{SiO}_2)_2$ . Cobalt-ultramarine or Thénard's blue, and *Cæruleum*, are essentially salts of Co chiefly phosphates and arsenates. Cobalt-green or *Rivian's green* contains Co and Zn oxides, and sometimes a little  $\text{As}_2\text{O}_3$ ; it is prepared by evaporating mixed solutions of Co and Zn salts and strongly heating the residue. (For details of these colouring matters v. *DICTIONARY OF TECHNICAL CHEMISTRY.*) M. M. P. M.

COBRA POISON (*A. Pedler, Pr.* 27, 17; Blyth, *Analyst*, i. 204; Warden, *C. N.* 54, 197). Two-thirds of the organic matter in the poison of *Naja tripudians* is of albuminous character,

being ppd. by alcohol, the poisonous substance is soluble in alcohol.  $\text{NH}_3$  is not an antidote, but  $\text{HCl}$  retards the physiological action, while  $\text{HCl}$  and platinum chloride form a salt,  $(\text{C}_{17}\text{H}_{21}\text{N}_2\text{O}_7\text{HCl})_2\text{PtCl}_4(?)$ , which is not poisonous.  $\text{AuCl}_3$  and  $\text{KMnO}_4$  mixed with the poison before injection prevent death; but after the poison has been injected, the subsequent injection of these liquids will not prevent death (T. L. Brunton & Sir J. Payrer, *Pr.* 27, 465). A poisonous crystalline substance may be obtained by dialysing the poison.

**COCAINE**  $\text{C}_{17}\text{H}_{21}\text{NO}_4$ . Benzoyl-methyl-ecgonine. [98°]. S. 14 at 12°.

**Occurrence.**—In the leaves of *Erythroxylon Coca* of South America (Niemann, *Ar. Ph.* [2] 103, 120, 291; A. 114, 213). These leaves are chewed by the inhabitants.

**Formation.**—In small quantity by heating together ecgonine, benzoic anhydride and methyl-iodide at 100° for 10 hours (Merck, B. 18, 2952).

**Preparations.**—1. Coca leaves are digested with ether; the ether is evaporated and the residue extracted with boiling water; the solution is mixed with magnesia and evaporated and the cocaine extracted by amyl alcohol (Trupheme, *C. C.* 1881, 447).—2. The leaves are extracted with alcohol, colouring matter is ppd. by lime, and the filtrate evaporated to a small bulk and mixed with water. The alkaloid is then ppd. by  $\text{K}_2\text{CO}_3$  and dissolved in ether and decolorised by animal charcoal (Schull, *Ph.* [3] 10, 408).

**Properties.**—Small monoclinic prisms;  $a:b:c = 1.186:1.1:223$ ;  $\beta = 73^\circ 50'$  (Tscherniak, *Sitz.* W. 48, i. 34); v. sl. sol. water, v. sol. hot alcohol and ether. Conc.  $\text{H}_2\text{SO}_4$  dissolves it without colour. It produces insensibility to pain in the tongue, eye, or other part touched by it. Taken internally it acts somewhat like opium (Kennedy, *Ph.* [8] 10, 65; J. Grasset, *C. R.* 99, 983, 1122; 100, 364; Richard, *C. R.* 100, 1409; Lafont, *C. R.* 105, 1278; Sighicelli, *C. C.* 1887, 1150). An injection of cocaine acts as a cerebro-spinal stimulant or anti-narcotic (Mosso, *Ar. Ph.* [3] 26, 179). Solutions of salts of cocaine are ppd. by  $\text{KOH}$ ,  $\text{NH}_3$ , and  $\text{Na}_2\text{CO}_3$ ; the pp. is soluble only in a large excess of  $\text{KOH}$ , but insol.  $\text{NH}_3$ . Ammonium carbonate gives a pp. sol. excess. Picric acid, tannin and  $\text{HCl}$ , potassium-mercuric iodide, iodine solution,  $\text{SnCl}_4$ ,  $\text{AuCl}_3$ , and  $\text{PtCl}_4$  also give pps. By heating with conc.  $\text{HCl}$  cocaine is split up into ecgonine  $\text{C}_{15}\text{H}_{19}\text{NO}_3$ , methyl alcohol, and benzoic acid (Lossen, *A.* 133, 351). Cocaine, freshly ppd. by  $\text{NH}_3$  and left under water, slowly decomposes forming  $\text{MeOH}$  and benzoyl-ecgonine (Paul, *Ph.* [8] 18, 783). The specific rotation in chloroform solution at 20° is given by the formula:  $[\alpha]_D = -(15.827 + 0.0585 q)$ , where  $q$  = weight of chloroform in 100 pts. by weight of the solution, and the tube is 100 mm. long. If  $q = 0$  then  $[\alpha]_D = -15.827$ .

**Salts.**— $\text{B}^+\text{HCl}^-$ : the melting-point varies in different preparations between [181°] and [185°]. For its medicinal employment its absolute purity is essential, and this is best determined by taking its specific rotation. In dilute alcoholic solution at 20°, with a tube 100 mm. long, the specific rotation is given by the formula:  $[\alpha]_D = -(52.18 + 1.688 q)$ , and

$[\alpha]_D = -(67.982 - 1.5827 q)$ , where  $q$  = weight of dilute alcohol of S.G.  $\frac{2}{3}$  9558 (mixture of 6 pts. by weight of absol. alcohol to 9 pts. by weight of water) in 100 pts. by weight of the solution, and  $q$  = weight of cocaine hydrochloride in 100 pts. by vol. of the solution. When  $q = 0$ , then  $[\alpha]_D = 52.2$ ; when  $q = 100$ , then  $[\alpha]_D = 68.0$  (Antrick, *B.* 20, 310).— $\text{B}^+\text{H}_2\text{PtCl}_6^-$ — $\text{B}^+\text{H}_2\text{AuCl}_6^-$ — $\text{B}^+\text{H}_2\text{C}_6\text{O}_4^-$ : feathery crystals.

**Amorphous cocaine.** An amorphous alkaloid accompanies cocaine in coca-leaves. It is v. sol. alcohol and ether. Its hydrochloride is amorphous, and its solution partially decomposes on evaporation, becoming acid (Paul, *Ph.* [3] 18, 784). According to Hesse (*Ph.* [3] 18, 71) this base is isomeric with cocaine (cf. Stockman, *Ph.* [3] 17, 861; Howard, *Ph.* [3] 18, 71; Bender, *C. C.* 1885, 490. *V. also* ECAGONINE).

**COCATANNIC ACID**  $\text{C}_{17}\text{H}_{19}\text{O}_6$ . [189°]. Occurs in coca leaves (Warden, *Ph.* [3] 18, 985). Gives a red colour with  $\text{KOH}$ .  $\text{FeSO}_4$  and  $\text{FeCl}_3$  give a dark-green colour.  $\text{Pb}(\text{OAc})_2$  gives a rose-red pp. It reduces alkaline silver solution, but not Fehling's solution. Potash-fusion gives butyric and traces of benzoic acids.

**COCCERIC ACID**  $\text{C}_{20}\text{H}_{30}\text{O}_8$ . [93°]. Formed, together with cocceryl alcohol, by saponification of coccerin, the wax of cochineal. White crystalline powder. Sol. hot alcohol, ether, benzene, &c., sl. sol. the cold solvents. On oxidation with  $\text{CrO}_3$  and acetic acid it gives pentadecic acid, the same product as from cocceryl alcohol (Liebermann & Bergami, *B.* 20, 964).— $\text{A}^+\text{Ca}$  and  $\text{A}^+\text{Ba}$ : flocculent pps.

**Ethyl ether AEt.** [c. 70°] (Liebermann, *B.* 18, 1980).

**COCCEKIN**  $\text{C}_{20}\text{H}_{30}(\text{O} \cdot \text{C}_{10}\text{H}_{19})_2$ . *Cocceryl coccerate*. [106°]. Occurs in cochineal in quantity varying from 1 p.c. to 4 p.c. and is obtained by extraction with benzene. The cocoons of the cochineal insect consist of coccerin to the extent of  $\frac{2}{3}$  of their weight (Liebermann, *B.* 19, 323). Thin glistening plates. Sl. sol. all cold solvents, nearly insol. alcohol and ether. On saponification with alcoholic  $\text{KOH}$  it gives cocceryl alcohol  $\text{C}_{20}\text{H}_{30}(\text{OH})_2$  and cocceric acid  $\text{C}_{11}\text{H}_{18}\text{O}_4$  (Liebermann, *B.* 18, 1975).

**COCCEKYL ALCOHOL**  $\text{C}_{20}\text{H}_{30}(\text{OH})_2$ . [101°–104°]. Formed, together with cocceric acid, by saponification of coccerin, the wax of cochineal (Liebermann, *B.* 18, 1975). White crystalline powder. On oxidation with  $\text{CrO}_3$  and acetic acid it gives pentadecic acid  $\text{C}_{11}\text{H}_{18}\text{O}_4$ , and probably also an acid  $\text{C}_{10}\text{H}_{16}\text{O}_3$ .

**Acetyl derivative**  $\text{C}_{20}\text{H}_{30}(\text{OAc})_2$ . [50°]; crystalline solid; v. sol. ether, warm alcohol, and acetic acid; v. sl. spl. acetone.

**Benzoyl derivative**  $\text{C}_{20}\text{H}_{30}(\text{OBz})_2$ . [62°]; crystalline solid; v. sol. ether, warm alcohol, and acetic acid, v. sl. sol. acetone (Liebermann & Bergami, *B.* 20, 959).

**COCCEKININ** v. CARMINO ACID.

**COCCEKGININ**  $\text{C}_{20}\text{H}_{30}\text{O}_4$ . A crystalline substance occurring in the seeds of *Daphne Mezereum*. Sl. sol. water, v. sol. alcohol and ether. May be sublimed, when it emits an odour like coumarin. Boiling dilute  $\text{H}_2\text{SO}_4$  forms no glucose from it (Casselmann, *Z.* [2] 6, 691).

**COCULIN**  $\text{C}_{11}\text{H}_{14}\text{O}_4$ . Occurs in *coccidius indicus*. Found in small quantities in the pre-

paration of picrotoxin (*q. v.*), from which it can be separated by means of absolute alcohol, and recrystallised from hot water acidulated with HCl. Conc.  $\text{H}_2\text{SO}_4$  colours it pale yellow, disappearing on stirring (Löwenhardt, *A.* 222, 353).

**COCETHYLINE**  $\text{C}_{11}\text{H}_{19}\text{NO}_3$ . [109°]. Obtained by heating benzoyl-ecgonine with ethyl iodide for 8 hours at 100°. Splendid glistening prisms. Has an anæsthetic action.  $\text{PtCl}_4$  gives with very dilute solutions of the hydrochloride a yellow pp. of the platino-chloride  $\text{B}'_{12}\text{H}_2\text{Cl}_2\text{PtCl}_4$ , which crystallises from a large quantity of hot water in glittering yellow rhombic plates.  $\text{AuCl}_3$  gives a very sparingly soluble yellow pp.  $\text{HgCl}_2$  forms a white pp., sol. hot water (Merck, *B.* 18, 2954).

**COCHLEARIA OIL.** The essential oil of scurvy-grass (*Cochlearia officinalis*) is isobutyl thiocarbimide (Hofmann, *B.* 7, 508).

**COCOA NUT OIL or cocoa butter.** The following acids have been described as present in the product of saponification of this fatty oil: hexoic, octoic, decaic, lauric  $\text{C}_{12}\text{H}_{25}\text{O}_2$ , an isomeride of lauric [58°], tridecoic  $\text{C}_{13}\text{H}_{27}\text{O}_2$ , myristic, palmitic, stearic, oleic, and arachic acids. Kingzett (*C. J.* 33, 38) also found an acid  $\text{C}_{17}\text{H}_{33}\text{O}_2$  [72°] (Bromeis, *A.* 35, 86; Fehling, *A.* 53, 399; Gorgey, *A.* 66, 290; Oudemans, *J. pr.* 81, 367; Carr Robinson, *Tr. E.* 28, 277; Traub, *Ar. Ph.* [3] 21, 19).

**CODAMINE**  $\text{C}_{20}\text{H}_{39}\text{NO}_3$ . [126°] (from benzene); [121°] (from alcohol or ether). An alkaloid occurring in the aqueous extract of opium (Hesse, *A.* 153, 56; *Suppl.* 8, 280). Six-sided prisms (from ether); m. sol. boiling water, v. sol. benzene, alcohol, chloroform, and ether. Conc.  $\text{HNO}_3$  gives a green solution.  $\text{FeCl}_3$  aq gives a green colour. Conc.  $\text{H}_2\text{SO}_4$  gives a blue colour, changing to green, and to dark violet on warming.  $\text{NH}_3$  and KOH give pps. sol. excess.— $\text{B}'_2\text{H}_2\text{PtCl}_4$  2aq.  $\text{B}'\text{HI}$  1½aq.

**CODEINE**  $\text{C}_{18}\text{H}_{21}\text{NO}_3$ . *Methyl-morphine*. *Codeia*. [150°]. S.G. 1.32. S. 1.26 at 15°, 5.88 at 100°.  $[\alpha]_D = -134^\circ$  (in alcohol). S. (amyl alcohol) 15.68; S. (benzene) 9.60 (Kubly, *J.* 1866, 823).

*Synthesis.*—By gently heating morphine (1 mol.) with NaOH (1 mol.) and MeI (1 mol.) dissolved in alcohol (Grimaux, *C. R.* 92, 1140, 1228; Hesse, *A.* 222, 210). The yield is small, but by doubling the quantity of MeI a good yield of codeine methylo-iodide may be obtained. The codeine so prepared is levorotatory;  $[\alpha]_D = -130^\circ$ .

*Preparation.*—Aqueous extract of opium is freed from meconic acid by ppg. with  $\text{CaCl}_2$ , and the filtrate evaporated to crystallisation. The mixed hydrochlorides of morphine and codeine are dissolved in water and ppd. by ammonia; morphine is ppd. but codeine remains in solution. On evaporating the filtrate codeine hydrochloride crystallises out (Robiquet, *A. Ch.* [2] 51, 259; *A.* 5, 106; Gregory, *A.* 7, 263; Anderson, *A.* 77, 341; *Ed. Phil. Trans.* 20, 57; cf. Couerbe, *A. Ch.* [2], 59, 158; Regnault, *A. Ch.* [2] 68, 186; Gerhardt, *Rev. Scient.* 10, 208; Winckler, *Rep. Pharm.* 44, 459; Merck, *A.* 11, 279; Plugge, *Ar. Ph.* [8] 35, 848).

*Properties.*—Trimetric crystals (containing aq). From  $\text{OS}_2$  it separates in anhydrous trimetric crystals  $\alpha:b\gamma = 980:1:509$  (Arzruni, *Z. K.*

1, 302). Levorotatory;  $[\alpha]_D$  (in alcohol) =  $-136^\circ$ ; (in  $\text{CHCl}_3$ ) =  $-112^\circ$  (Hesse, *A.* 176, 191; cf. Grimbert, *J. Ph.* [5] 16, 295). The rotatory power is much affected by the presence and amount of acid in solution (Hesse; Tykocimer, *R. Z. T. C.* 1, 144). It is a strong base, reddens litmus, and pps. salts of Pb, Fe, Cu, &c. Sol. ether. Codeine is insoluble in aqueous KOH and hardly more soluble in aqueous  $\text{NH}_3$  than in pure water. Its physiological action resembles that of morphine.

*Colour reactions.*—1.  $\text{H}_2\text{SO}_4$  forms a greenish solution which, after a week, becomes indigo blue.—2.  $\text{Fe}_2\text{Cl}_6$  gives no colour.—3.  $\text{H}_2\text{SO}_4$  and  $\text{Fe}_2\text{Cl}_6$  gives an intense blue (Lindo, *C. N.* 37, 158).—4. Chloride of iodine gives a yellowish pp. in solutions of salts of codeine.—5.  $\text{K}_2\text{Cr}_2\text{O}_7$  gives the chromate.—6.  $\text{K}_2\text{FeCy}_4$  gives no pp. (Plugge, *Ar. Ph.* [3] 25, 793).

*Reactions.*—1. Hot  $\text{H}_2\text{SO}_4$  decomposes it, and after diluting,  $\text{Na}_2\text{CO}_3$  pps. 'amorphous codeine' as a grey powder [100°], v. sol. alcohol, but ppd. therefrom by ether.—2. Heating with KOH gives off trimethylamine.—3. Heating with a large excess of conc.  $\text{HCl}$  aq forms 'chlorocodide'  $\text{C}_{18}\text{H}_{25}\text{ClNO}_2$ , apomorphine, and  $\text{MeCl}$ .—4. HBr gives 'bromocodide'  $\text{C}_{18}\text{H}_{25}\text{BrNO}_2$ , 'deoxy-codeine'  $\text{C}_{18}\text{H}_{21}\text{NO}_2$  (sol. ether), and 'bromo-tetra-codeine'  $\text{C}_{18}\text{H}_{25}\text{Br}_2\text{N}_2\text{O}_2$  (insol. ether) (Matthiessen, *A.* Wright, *Pr.* 17, 460; 18, 83; Wright, *Pr.* 19, 371, 604).—5. HI and P at 100° to 130° forms some amorphous substances (Wright, *Pr.* 20, 8).—6. Codeine (1 pt.) evaporated with  $\text{HPO}_3$  (3 pts.) and water (5 pts.) is partly converted into dicodeine  $\text{C}_{36}\text{H}_{42}\text{N}_2\text{O}_4$  and tetracodeine  $\text{C}_{72}\text{H}_{84}\text{N}_4\text{O}_8$  (Matthiessen, *A.* Wright, *Pr.* 18, 87).—7. Alkaline  $\text{KMnO}_4$  expels half the nitrogen as  $\text{NH}_3$  (Wanklyn, *A.* Gamgee, *C. J.* 21, 25).—8.  $\text{PCl}_5$  forms two bases  $\text{C}_{18}\text{H}_{25}\text{ClNO}_2$  and  $\text{C}_{18}\text{H}_{21}\text{Cl}_2\text{NO}_2$  (v. Gerichten, *A.* 210, 107).—9. Cyanogen, passed into a conc. alcoholic solution of codeine, forms crystals of  $\text{C}_{18}\text{H}_{21}\text{NO}_3\text{Cy}$ .

*Salts.*— $\text{B}'\text{HCl}$  2aq; radiate groups of prisms S. 5 at 15.5°  $[\alpha]_D = -103^\circ$ .— $\text{B}'_2\text{H}_2\text{PtCl}_4$  4aq; light yellow powder, gradually becoming crystalline.— $\text{B}'\text{HI}$  aq; long thin needles. S. 1.3.— $\text{B}'\text{HI}$ ; red crystals with violet reflex.— $\text{B}'\text{HI}$ .— $\text{B}'\text{HNO}_3$ ; small prisms, v. sol. hot water.— $\text{B}'_2\text{H}_2\text{C}_2\text{O}_4$  3aq; prisms or scales. S. 3.3 at 15.5°, 200 at 100°.— $\text{B}'\text{H}_2\text{PO}_4$  1½aq; scales or prisms.— $\text{B}'_2\text{H}_2\text{SO}_4$  5aq; trimetric prisms. S. 8.3 in the cold  $[\alpha]_D = -101^\circ$  at 20°.— $\text{B}'\text{H}_2\text{S}_2\text{O}_5$  5aq; prisms S. 5.6.— $\text{B}'\text{HSCy}$  4aq. [100°]. Radiating needles. Chloro-acetate  $\text{B}'\text{C}_2\text{Cl}_2\text{H}_3\text{O}_2$  [154°].—Di-chloro-acetate  $\text{B}'\text{C}_2\text{Cl}_2\text{H}_3\text{O}_2$  [156°].—Tri-chloro-acetate  $\text{B}'\text{C}_3\text{Cl}_3\text{H}_3\text{O}_2$  [138°].—Chloro-crotonate  $\text{B}'\text{C}_2\text{H}_3\text{ClO}_2$  [171°].—Tri-chloro-butyrate  $\text{B}'\text{C}_3\text{H}_3\text{Cl}_3\text{O}_2$  [178°].—Di-bromo-pyruvate  $\text{B}'\text{C}_2\text{H}_3\text{Br}_2\text{O}_2$  [70°] (Dacomo, *J.* 1884, 1885).

*Acetyl derivative*  $\text{C}_{18}\text{H}_{23}\text{AcNO}_3$ . [135°] From codeine and  $\text{Ac}_2\text{O}$  (Wright, *C. J.* 27, 1031; Hesse, *A.* 222, 212).— $\text{B}'\text{HCl}$  2aq.— $\text{B}'_2\text{H}_2\text{PtCl}_4$ .

*Propionyl derivative*  $\text{C}_{18}\text{H}_{23}(\text{C}_2\text{H}_5\text{O})\text{NO}_3$ . From codeine and propionic anhydride. V. sol. alcohol, ether, and benzene. Conc.  $\text{H}_2\text{SO}_4$  gives a blue colour. Forms well-crystallised salts.— $\text{B}'\text{HCl}$  2aq.— $\text{B}'_2\text{H}_2\text{PtCl}_4$ .— $\text{B}'\text{HI}$  aq.— $\text{B}'\text{H}_2\text{C}_2\text{O}_4$  8aq (Hesse, *A.* 222, 212).

*Butyryl derivative*  $\text{C}_{18}\text{H}_{23}(\text{C}_4\text{H}_7\text{O})\text{NO}_3$

Amorphous (Beckett a. Wright, *C. J.* 28, 15).— $B'HCl$  8aq.— $B'H_2PtCl_6$ .

**Benzoyl derivative**  $C_{18}H_{21}(C_6H_5O)NO$ . Crystallises from ether.— $B'HCl$  aq.— $B'H_2PtCl_6$ .

**Succinoyl derivative**  $C_{18}H_{21}NO_3(CO_2CH_2CH_2CO_2H)$  5aq. Formed by heating codeine (1 pt.) with succinic acid (2 pts.) at  $180^\circ$  (Beckett a. Wright, *C. J.* 28, 689). Insol. water, ether, and benzene.— $B'HCl$  aq.— $B'H_2PtCl_6$ .

**Camphoryl derivative**  $C_{18}H_{21}NO_3(C_{10}H_{15}O_3)$ . From codeine and camphoric acid at  $180^\circ$ . Crystalline.— $B'HCl$  3aq.— $B'H_2PtCl_6$ .

**Methyl iodide**  $C_{18}H_{21}NO_3MeI$ . Prepared from codeine and methyl iodide, or from morphine, methyl iodide and sodium in presence of alcohol. Fine needles when hydrated: hard voluminous crystals when anhydrous. With moist silver oxide yields a hydroxyl derivative converted by dehydration into methyl codeine (*q. v.*) (Grimaux, *A. Ch.* [5] 27, 276; *C. R.* 93, 691). By successive treatment with  $Ac_2O$  and  $AgOAc$  it is converted into  $C_{17}H_{19}O_3$  [131°] which crystallises from alcohol in needles (Fischer, *B.* 19, 794).

**Ethyl iodide**  $C_{18}H_{21}NO_3EtI$ . Formed by heating codeine with  $EtI$  and alcohol at  $100^\circ$  (How, *C. J.* 6, 125). Crystalline mass, v. sol. water. Not decomposed by  $KOH$  but converted by  $Ag_2O$  into a very alkaline hydroxide. The hydroxide changes, when its alkaline solution is evaporated, into ethyl-codeine. Acetyl derivative  $C_{18}H_{21}AcNO_3EtI$  3aq: crystals, v. sl. sol. cold alcohol (Beckett a. Wright, *C. J.* 28, 318). Gives rise to  $C_{18}H_{21}AcNO_3EtCl$  and ( $C_{18}H_{21}AcNO_3EtCl$ ) $PtCl_6$ . Butyryl derivative  $C_{18}H_{21}(C_4H_7O)NO_3EtI$  3aq.

**Chloride**  $C_{18}H_{21}ClNO_3$ . *Codeyl chloride*. [147°]. Formed by treating codeine with  $PCl_5$  mixed with  $POCl_3$ . Colourless leaflets; insol. water, sol. alcohol and ether (v. Gerichten, *A.* 210, 105).— $B'H_2PtCl_6$ .

**Chloro-codide**  $C_{18}H_{21}ClNO_3$ . Formed by prolonged heating of codeine (1 pt.) with conc.  $HCl$  (12 pts.) at  $100^\circ$  (Matthiessen a. Wright, *Pr.* 17, 460; 18, 83; *A. Suppl.* 7, 304). Amorphous; v. sol. alcohol and ether. Water at  $140^\circ$  gives  $HCl$  and codeine. Conc.  $HCl$  at  $140^\circ$  gives  $MeCl$  and apomorphine.— $B'HCl$ : amorphous.— $B'H_2PtCl_6$ .

**Bromo-codide**  $C_{18}H_{21}BrNO_3$ . From codeine and  $HBr$  aq. (S.G. 1.5) at  $100^\circ$  (Wright, *Pr.* 19, 371). Unstable.— $B'HBr$ : gummy.

**Chloro-codeine**  $C_{18}H_{21}ClNO_3$  13aq. [170°]. From codeine,  $KClO_4$  and  $HCl$ . Crystalline powder; sl. sol. ether and hot water, v. e. sol.  $NH_4Aq$ .— $B'H_2SO_4$  4aq: prisms.— $B'H_2PtCl_6$ .

**Chloride**  $C_{18}H_{21}ClNO_3$ . *Chloro-codeyl chloride*. [196°]. Formed by heating codeine (1 mol.) with  $PCl_5$  (2½ mols.) and  $POCl_3$  at  $70^\circ$  (v. Gerichten, *A.* 210, 105). Trimetric prisms; insol. water, v. sol. alcohol, ether, and benzene. Its hydrochloride crystallises in grouped needles.— $B'H_2PtCl_6$ .

**Bromo-codeine**  $C_{18}H_{21}BrNO_3$ . [162°]. From codeine and bromine-water. Needles (containing ½ aq. or 1 aq.). V. sl. sol. water, v. e. sol.  $NH_4Aq$ .— $B'H_2PtCl_6$ .— $B'HBr$  aq: prisms.

**Ethyl-hydrate**  $B'EtOH$ . Decomposes

on evaporation of its aqueous solution forming bromo-ethyl-codeine (*B.* 15, 1485).

**Chloride**  $C_{18}H_{21}BrClNO_3$ . [131°]. From bromo-codeine and  $PCl_5$ . Prisms; sol. alcohol and ether.

**Tri-bromo-codeine**  $C_{18}H_{21}Br_3NO_3$ . From bromo-codeine and bromine-water (Anderson). Amorphous powder.— $B'H_3HBr$ .— $B'H_2PtCl_6$ .

**Di-iodo-codeine**  $C_{18}H_{21}I_2NO_3$  (?). From codeine hydrochloride and  $ICl$ . Crystals (from alcohol). Insol. water.— $B'H_2PtCl_6$  aq.

**Nitro-codeine**  $C_{18}H_{21}(NO_2)NO_3$ . From codeine and hot dilute  $HNO_3$  (S.G. 1.06). Silky laminae (from alcohol). Sl. sol. boiling water (Anderson).— $B'H_2PtCl_6$  4aq.— $B'H_2SO_4$  2aq (at  $100^\circ$ ): radiating needles.

**Dicodene** ( $C_{18}H_{21}NO_3$ ), 2aq. Formed by heating codeine with dilute  $H_2SO_4$  with  $P_2O_5$ , or with oxalic acid (Anderson, *Ed. Phil. Trans.* 20 [1] 57; Armstrong, *C. J.* 24, 56; Wright, *C. J.* 25, 506; 28, 312, 696). Amorphous powder. Insol. water, sol. alcohol and ether. Immediately ppd. from its salts by  $Na_2CO_3$  (codeine comes down only after some time).  $FeCl_3$  gives no colour.  $HNO_3$  gives a pale orange tint. Hot conc.  $HCl$  converts it into  $C_{17}H_{19}ClIN_3O_3H_2Cl$ .  $HI$  and phosphorus at  $120^\circ$  form  $C_{18}H_{13}IN_3O_3H_2I_2$  (?).

Salt.— $B'H_2Cl$  6aq.

**Acetyl derivative** ( $C_{18}H_{21}AcNO_3$ ). From dicodene and  $Ac_2O$  (Beckett a. Wright, *C. J.* 28, 15). Amorphous; v. sol. ether.— $B'H_2Cl$  5aq: crystalline.— $B'H_2PtCl_6$ .

**Tricodene** ( $C_{18}H_{21}NO_3$ ). A product of the action of  $H_2SO_4$  or of  $ZnCl_2$  on codeine (Wright, *C. J.* 25, 507; 27, 101; *Pr.* 20, 203). Amorphous. Sol. alcohol and ether. Its hydrochloride is amorphous and extremely deliquescent. Conc.  $HCl$  converts it on heating into apocodene.  $FeCl_3$  gives no colour at first, but afterwards a reddish-purple.  $HNO_3$  gives a blood-red colour.  $Na_2CO_3$  immediately pps. it from solutions of its salts (difference from codeine). Hot concentrated hydrochloric acid forms  $C_{18}H_{11}N_3O_3H_2Cl$ .

**Tetracodene** ( $C_{18}H_{21}NO_3$ ). From codeine and  $P_2O_5$ . Formed also by boiling codeine with benzene and  $NaOEt$  (Wright, *C. J.* 27, 107; 28, 324). Amorphous; sol. alcohol; insol. ether. Its hydrochloride is amorphous and deliquescent.  $FeCl_3$  gives immediately a reddish-purple colour.  $HNO_3$  gives a blood-red colour.  $K_2Cr_2O_7$  and  $H_2SO_4$  gives an evanescent red colour (this reaction is given also by tricodene, but no colour is got with codeine or dicodene).  $Na_2CO_3$  immediately pps. tetracodene from its salts. Boiling aqueous  $HCl$  has no action. Boiling  $HI$  and phosphorus form  $C_{18}H_{13}IN_3O_3H_2I_2$  (?).

**Acetyl derivative** ( $C_{18}H_{21}AcNO_3$ ). From tetracodene and  $Ac_2O$  at  $120^\circ$ . Amorphous.— $B'H_2PtCl_6$ .

**Bromo-tetracodene**  $C_{18}H_{21}BrNO_3$ . From codeine and  $HBr$ .  $HCl$  forms  $C_{17}H_{19}ClIN_3O_3H_2Cl$ . Hydric bromide forms bromo-tetramorphine  $C_{18}H_{21}BrN_3O_3$ .

Salt.— $C_{18}H_{21}BrN_3O_3H_2Br$ .

**Deoxycodene**  $C_{17}H_{19}NO_3$ . From codeine and  $HBr$ . Insol. water, sol. alcohol and ether. Turns brown in air.— $B'HBr$ : small crystals.

**Apocodene**  $C_{17}H_{19}NO_3$ . Formed by heating codeine hydrochloride with a conc. solution of  $ZnCl_2$  for 15 minutes (Matthiessen a. Burnside,

Fr. 19, 71). Gummy mass; insol. water, sol. alcohol and ether. Gives a blood-red colour with  $\text{HNO}_3$ .— $\text{B'HOI}$ : amorphous. Acts as a mild emetic.

**Methyl-codeine**  $\text{C}_{15}\text{H}_{21}\text{NO}_4$ . *Di-methyl-morphine*. [119°]. Prepared by evaporating the product of the action of silver oxide, or of KOH, on codeine methyl-iodide. The substance separates out as an oil, which solidifies on desiccation. Hard, brilliant laminae. It appears to possess all the properties of a tertiary base and to be formed by the dehydration of methyl codeine hydroxide. With sulphuric acid it gives a brown colouration, turning violet on addition of water (Grimaux, *J. Ch.* [5] 27, 283).

**Ethyl-codeine**  $\text{C}_{17}\text{H}_{23}\text{EtNO}_4$ . Formed by evaporation of a solution of codeine ethyl-hydroxide.

**Methylo-iodide**  $\text{C}_{15}\text{H}_{21}\text{EtNO}_4\text{MeI}$ . Readily formed by the union of MeI with ethyl-codeine.

**Methylo-hydroxide**  $\text{B'MeOH}$ . Formed by the action of moist  $\text{Ag}_2\text{O}$  on the methylo-iodide. On heating to 130° it decomposes into methyl-ethyl-propyl-amine and a body  $\text{C}_{15}\text{H}_{21}\text{O}_2$  (Gerichten & Schrötter, *B.* 15, 1486). The compound  $\text{C}_{15}\text{H}_{21}\text{O}_2$  [55°] is converted into phenanthrene by distillation with zinc-dust. According to Grimaux (*C. R.* 93, 591), a crystalline tertiary base (? methyl-ethyl-codeine) [132°] is formed by heating ethyl-codeine methylo-iodide with moist  $\text{Ag}_2\text{O}$  or KOH.

**Bromo-ethyl-codeine**  $\text{C}_{17}\text{H}_{23}\text{EtBrNO}_4$ . Long white needles. Sol. acids and strong  $\text{NH}_3$ . Tertiary base. Formed by evaporation of a solution of the ethyl-hydrate of bromo-codeine.

**Ethyl-hydrate**  $\text{B'MeOH}$ . Formed by the action of moist  $\text{Ag}_2\text{O}$  on the methylo-iodide. On evaporating the solution to dryness it decomposes into methyl-ethyl-propyl-amine and a body  $\text{C}_{15}\text{H}_{21}\text{BrO}_2$  (Gerichten & Schrötter, *B.* 15, 1485). This compound  $\text{C}_{15}\text{H}_{21}\text{BrO}_2$  [122°] is converted by  $\text{CrO}_3$  into a substance which is apparently a quinone.

**DICODETHINE** v. *Ethylene-MORPHINE*.

**CODETHYLENE** v. *Ethyl-MORPHINE*.

**CERULEIN**  $\text{C}_{20}\text{H}_{24}\text{O}_4$  i.e.

**Formation**.—1. By heating gallein with concentrated sulphuric acid at 190°–200°, an olive-brown solution is formed, from which the cerulein is precipitated by water.—2. By oxidation of cerulin.

**Properties**.—Dark-blue, metallic glistening crystals, sl. sol. water, alcohol and ether. When heated with zinc-dust phenyl-anthracene is produced.

**Triacetyl derivative**  $\text{C}_{20}\text{H}_{24}\text{O}_7(\text{OAc})_3$ , red needles, sol. alcohol, acetone and chloroform, readily decomposed with separation of cerulein (Buchka, *A.* 209, 272).

**CERULIN**  $\text{C}_{20}\text{H}_{24}\text{O}_4$  i.e.

$\text{C}_6\text{H}_4 \begin{array}{c} \diagup \quad \diagdown \\ \text{C} \quad \text{C}_6\text{H}_2(\text{OH}) \\ \diagdown \quad \diagup \\ \text{C}(\text{OH}) \quad \text{C}_6\text{H}_2(\text{OH}) \end{array} \gg \text{O}$ . Formed by the action of concentrated sulphuric acid on gallein; formed also by reduction of cerulein with ammonia and zinc-dust (Baeyer, *B.* 4, 555, 553); the solution is acidified and agitated with ether, on

evaporation of which cerulin is left as a red substance, sol. alcohol, ether and acetic acid with golden-green fluorescence. It is readily oxidised to cerulein.

**Tetra-acetyl derivative**

$\text{C}_{20}\text{H}_{24}\text{O}_8(\text{OAc})_4$ . [256°]. Cannot be prepared directly from cerulin, but indirectly from cerulein, acetic anhydride and zinc-dust; yellow needles sol. alcohol, chloroform and benzene, converted on oxidation into tri-acetyl-cerulein.

**Constitution**.—Cerulein bears to gallein (*q. v.*) the same relation that phenol-phthalidin bears to phenol-phthalin, as shown by its analogous method of formation (Buchka, *A.* 209, 274).

**CERULIGNOL**  $\text{C}_{15}\text{H}_{21}\text{O}_2$  i.e.  $\text{C}_6\text{H}_5(\text{OMe})(\text{OH})$ . *Blue-oil*. [241° cor.]. S.G. 1.06. Obtained first by Reichenbach among the higher boiling portions of beech-tar oil, and characterised by giving a blue colouration with baryta water. Is best separated by boiling the oil for some time with acetic acid just strong enough to dissolve it. On pouring the solution into water the compound separates out. Colourless oil, of creosote-like odour, m. sol. hot water, alcohol, ether and acetic acid. From its reaction with nitrobenzene and strong sulphuric acid it appears to be a homologue of pyrocatechin, probably of guaiacol (Pastrovich, *M.* 4, 188). It gives a blue colouration with baryta water or bleaching powder; with ferric chloride in alcoholic solution, a green, but in aqueous solution, a carmine-red colouration. Heated with hydrochloric acid it forms a substance  $\text{C}_{15}\text{H}_{21}\text{O}_2$  i.e.  $\text{C}_6\text{H}_5(\text{OH})$ , crystallising in prisms [55°]. On melting it evolves methyl chloride.

**Acetyl derivative**  $\text{C}_{15}\text{H}_{21}\text{AcO}_2$  (265°); viscid, colourless oil, once obtained in fan-shaped crystals.

**Nitro-derivative**  $\text{C}_{15}\text{H}_{21}\text{NO}_2$  [124°], obtained together with oxalic acid, the principal product, by the action of nitric acid (S.G. 1.12) on cerulignol. Light yellow crystals, sol. water and alcohol.

**CERULIGNONE**  $\text{C}_{15}\text{H}_{16}\text{O}$  i.e.  $\text{O.C}_6\text{H}_4(\text{OMe})_2$

$\text{O.C}_6\text{H}_4(\text{OMe})_2$

**Tetramethyl-ether of tetra-oxy-diphenylene-quinone**. *Codrinet*. One of the products obtained by Reichenbach from beechwood tar (*J. pr.* 1, 1). The crude acetic acid prepared from wood is treated with  $\text{K}_2\text{Cr}_2\text{O}_7$ , which oxidises the di-methyl-ether of pyrogallol that is present (Liebermann, *B.* 5, 746; 6, 381; *A.* 169, 231; Hofmann, *B.* 11, 335). It is purified by solution in phenol and ppn. by alcohol or ether. Small dark steel-blue needles. Insol. ordinary solvents; cannot be distilled. Dissolves in conc.  $\text{H}_2\text{SO}_4$  with blue colour, but is decomposed thereby with elimination of one or two methyl groups. Heated with aqueous KOH it forms a green solution, quickly becoming yellow. *Potash-fusion* gives an intense but fugitive violet colour. Reducing agents convert it into hydrocerulignone  $\text{C}_{15}\text{H}_{18}\text{O}_2$  [190°] which is the tetra-methyl-ether of HEXA-OXY-DIPHENYL (*q. v.*).

**Cerulignone of the ethyl series**

$\text{C}_6\text{H}_4(\text{OEt})_2\text{O}$ . Greenish-golden glistening  $\text{C}_6\text{H}_4(\text{OEt})_2\text{O}$  prisms. Prepared by the oxidation of diethyl-pyrogallol with chromic acid in acetic acid.

May be reduced to the hydro-derivative  $C_{12}H_{19}(OH)_2(OH).C_2H_5(OEt)_2(OH)$  [176°] which crystallises in long white needles (Hofmann, B. 11, 801).

**Di-bromo-hydrococerulignone v. Hexa-oxo-diphenyl.**

**COFFEE v. CAFFEINE and CAFFEOL.**

**COLCHICINE**  $C_{20}H_{21}NO_6$ , i.e.

$C_{12}H_{19}(OMe)_2(NHAc)(CO_2Me)$  (?). *Methyl ether of colchicine* [145°]. Occurs in all parts of the meadow-saffron (*Colchicum autumnale*), especially in the seeds (Pelletier & Caventou, A. Ch. [2] 14, 69; Geiger & Hesse, A. 7, 274; Hübschmann, Ar. Ph. [2] 92, 330; Aschoff, Ar. Ph. [2] 89, 4; Bley, Ar. Ph. [2] 89, 18; Hübler, C. C. 1865, 536; Flückiger, Ph. [3] 7, 372; Hertel, C. C. 1881, 501; Ph. [3] 12, 498; Rosenwasser, Ph. [3] 8, 507; Houdes, C. R. 98, 1442; Zeisel, C. R. 98, 1687; M. 4, 162; 7, 557; 9, 1).

**Preparation.**—The whole seeds are extracted with hot 90 p.c. alcohol, and the residue digested with water. The aqueous solution is shaken with  $CHCl_3$ . On evaporation the chloroform leaves a syrupy residue, which after some days begins to crystallise. It is recrystallised repeatedly from alcohol and chloroform, and finally from water (Zeisel).

**Properties.**—Yellowish-white powder. Sol. water and alcohol, insol. ether; darkens when exposed to the light. It is laevorotatory. Mineral acids colour the solution yellow. Weak alkalis also give a yellow colour; concentrated acids yield a yellow resinous pp. Conc.  $HNO_3$  gives a violet colour. Conc.  $H_2SO_4$  with a trace of nitrate gives a yellow green. Br water a yellow pp. Iodine in KI a brown pp.  $FeCl_3$  no colour except on warming, when a green colour is produced.  $HgCl_2$  in neutral solutions gives a slight turbidity, when acid a yellow pp.  $AuCl_3$  yellow needles,  $CdI_2$ , potassium bismuth iodide, potassium mercuric chloride, phosphotungstic and phosphomolybdic acids, and chromates give yellow pps. Tannic acid in acid and neutral solution a white pp. It forms an addition compound with  $CHCl_3$  of the formula  $C_{20}H_{21}NO_6.2CHCl_3$  with evolution of heat. Yellow needles decomposed by water. Phenol gives a milkiness, and finally a yellow resin. Colchicine acts as a diuretic, purgative, and irritant poison (Mairet & Combemale, C. R. 104, 439, 515).

**Salts.**—Colchicine is a weak base, most of its salts being decomposed by water. The aurichloride  $B^H AuCl$  is stable.

**Colchicein**  $C_{17}H_{19}NO_5$ , i.e.  $C_{11}H_{15}(OMe)_2(NHAc)(CO_2H)$ . *Tri-methyl-acetyl-colchicinic acid* [c. 160°].

**Preparation.**—By warming an aqueous solution of pure colchicine with 2 p.c.  $H_2SO_4$  or 1 p.c.  $HCl$ . Separates in white needles. There are also formed methyl alcohol, an acid substance, and a new or possibly two new bases.

**Properties.**—Shining white needles (containing  $\frac{1}{2}$  aq.); becomes anhydrous at 140°–150°. Levorotatory. V. e. sol. alcohol and chloroform, insol. ether and benzene. Sol. mineral acids giving a yellow solution, in the case of  $HCl$  with rise of temperature. Alkalis also dissolve it, yielding yellow solutions. Conc.  $H_2SO_4$  and  $HNO_3$  behave with it as with colchicine. Br water, phosphomolybdic acid and aqueous phenol yield slight

agents. In  $HCl$  solution it behaves like colchicine with most reagents. From conc.  $HCl$  solution  $AuCl_3$  ppt. an orange-gold compound, which can be subsequently crystallised in needles. Lead and copper acetates give pps.  $HCl$  converts it into the hydrochloride of tri-methyl-colchicinic acid  $C_{17}H_{19}NO_5.HCl$  which forms a Pt salt  $(C_{17}H_{19}NO_5.HCl).PtCl_3.2aq$ . The dimethyl-colchicinic acid and colchicinic acid are also produced.

**Salts.**— $B^H AuCl$ ,  $(C_{17}H_{19}NO_5)_2Cu.5aq$  (Zeisel, M. 7, 585; 9, 8).

**Amide of colchicein.**

$C_{20}H_{23}N_3O_5$ , i.e.  $C_{12}H_{19}(OMe)_2(NHAc)(CONH_2)$  (?). Formed when colchicine and alcoholic  $NH_3$  are heated together in a sealed tube. After evaporating the alcohol a yellow crystalline mass is left, which is recrystallised from alcohol. Two kinds of crystals separate. Those which effloresce contain  $\frac{1}{2}$  mol. alcohol.

**Properties.**—Heated with  $NaHO$  it forms colchicein and  $NH_3$ . It behaves as a base, being sol.  $HCl$ , insol. water.  $FeCl_3$  gives a brown colouration, and in  $HCl$  solution  $KNO_3$  gives a violet colour, and the alkaloidal reagents give precipitates. Conc.  $H_2SO_4$  dissolves it, giving a yellow-red colouration (Zeisel, M. 9, 26).

**COLCHICINIC ACID**  $C_{17}H_{19}NO_6$ , i.e.  $C_{12}H_{19}(OH)_2(NH_2)(CO_2H)$  (?).

**Preparation.**—The hydrochloride remains in the mother-liquor after separating the dimethyl- and trimethyl-derivatives formed from colchicein by heating with  $HCl$ . After drying at 109° the colchicinic acid is obtained as a yellow powder.

**Properties.**— $HCl$  solution is ppd. by Br water,  $KI$ ,  $HgCl_2$ ,  $PtCl_3$ ,  $AuCl_3$ ,  $CdI_2$ , and by the usual alkaloidal reagents. Phenol gives no pp. Conc.  $H_2SO_4$  gives a brown colouration; if a nitrate be present, and then excess of  $NH_3$  added, a red colour is produced.  $FeCl_3$  gives a red-brown colouration (Zeisel, M. 9, 22).

**Dimethyl-derivative**  $C_{19}H_{21}NO_5$ , [142°]. The hydrochloride is formed with the trimethyl-derivative. It crystallises from hot water as  $B^H Cl$  aq, from which the free acid is obtained in yellow microscopic prisms by the addition of weak  $NaHO$ . These prisms contain  $\frac{1}{2}$  aq. A solution gives the usual alkaloid reactions (Zeisel, M. 9, 17).

**Trimethyl-derivative**  $C_{20}H_{23}NO_5$ , i.e.  $C_{12}H_{19}(OMe)_2(NH_2)(CO_2H)$ ? [150°]. From the hydrochloride formed from colchicein (q.v.). Microscopic prisms (containing 2 aq.). It forms a Pt salt  $(B^H Cl).PtCl_3.2aq$ .

**COLEIN**  $C_{10}H_{11}O_3$  (?) A brittle red resin, which may be extracted by acidulated alcohol from the leaves of *Coleus Verschoffeltii* (Church, C. J. 81, 258).

**COLLAGEN v. PROTEIDS, Appendix C.**

**COLLIDINE v. TRI-METHYL-PYRIDINE and METHYL-ETHYL-PYRIDINE.**

**COLLINIC ACID** obtained by Fröhde (J. pr. 80, 344) by oxidising gelatin with  $CrO_3$  is BENZOIC ACID.

**COLLODION v. CELLULOSE.**

**COLLOIDS.** Name given by Graham to those substances which do not diffuse through porous membranes. *Colloids* are contrasted with *Crystalloids*. V. DIFFUSION, and PHYSICAL METHODS.

**COLLOTURINE v. LOTURINE.**

**COLOCYNTHIN**  $C_{14}H_{18}O_{12}$  (?) S. (cold) 5; (hot) 1-8. The bitter principle occurring in the pulp of the fruit of *Citrullus Colocynthis* Vauquelin, *J. Phys.* 84, 388; Braconnot, *J. Ph.* 10, 415; Herberger, *Buchner's Repert.* 36, 368; Bastick, *Ph.* 10, 239; Walz, *Ar. Ph.* [2] 96, 141; 99, 338; Lebourdais, *A. Ch.* [3] 24, 58; Henke, *Ar. Ph.* [8] 21, 200).

**Preparation.**—The fruit is extracted with alcohol, the alcohol is evaporated, and the residue taken up by cold water; lead acetate is added, and in the filtrate, after removing the excess of lead by  $H_2SO_4$ , the colocynthin is pptd. by tannin. The compound with tannin is then decomposed by lead carbonate.

**Properties.**—Yellowish prisms or powder. Sol. water and alcohol, insol. ether,  $CS_2$ , benzene, chloroform, and ligroin. Conc.  $H_2SO_4$  gives a red colouration. It easily reduces Fehling's solution. Boiling aqueous HCl gives a dark green greasy pp., and the solution still reduces Fehling's solution. According to Walz, colocynthin is split up by boiling dilute  $H_2SO_4$  into glucose (2 mols.) and a resin colocynthcin  $C_{14}H_{18}O_{13}$ .

**COLOMBIN v. COLUMBIN.**

**COLOPHONE.** This name is applied by Armstrong and Tilden to the viscid yellow oil left after distilling all that is volatile in steam from the crude product of the action of  $H_2SO_4$  on the terpenes. It is probably a mixture of polymerides of these hydrocarbons (*C. J.* 35, 748). Deville (*A. Ch.* [2] 75, 66; [3] 27, 85) applied the name to the portion of the product of the action of  $H_2SO_4$  on French turpentine that boils a little above 300°. This might be called dicamphene,  $C_{20}H_{32}$ . A similar product occurs among the products of the distillation of colophony, but it differs from Deville's colophene in forming a grease when rubbed with slaked lime. *V. also TERPENES.*

**COLOPHONY v. TERPENES AND TURPENTINE.**

**COLUMBIC ACID**  $C_{12}H_{18}O_4$  aq? An acid which may be extracted by lime-water from Columbo root (Bödecker, *A.* 69, 47). Amorphous, nearly insol. water, v. sol. alcohol, sl. sol. cold ether.— $PhA'$ ,  $Pb(OH)_2$  aq?

**COLUMBIN**  $C_{21}H_{34}O_8$ . [182°]. S. (alcohol) 3 at 78°. Occurs in the Columbo root (from *Menispermum palmatin*, together with berberin and a substance [220°] which crystallises from HOAc in prisms. Prepared by extracting the root with ether. On evaporation a crystalline residue, together with a fatty substance, separates out; the latter is removed by washing with ether, and the former crystallised from alcohol (Wittstock, *P.* 19, 298; Liebig, *P.* 21, 80; Röse, *P.* 19, 441; Bödecker, *A.* 69, 89; Paterno and Ogialoro, *G.* 9, 66; Alessandri, *Ph.* [3] 12, 995). Tastes very bitter. *V. sl. sol. cold water, alcohol, and ether.*

**COMANIC ACID**  $C_8H_8O_2 \cdot CO_2H$  i.e.

**Preparation.**—1. Comenic acid (q.v.) is treated with  $PCl_5$  and the di-chloro-comenic acid produced is reduced by  $HI$  (b.p. 127°) (Ost, *J. pr.* [2] 29, 62).—2. Chelidonic acid is heated *in vacuo* at 280° (Haitinger, *A. Lieben, M.* 6, 279).

**Properties.**—Oblique prisms. Sl. sol. water. Gives no colour with  $FeCl_3$ .

**Reactions.**—1. Decomposed by excess of baryta with precipitation of the salt of an acid which gives a brown colour with  $FeCl_3$ . On warming the pp. with excess of baryta it changes to baric oxalate, acetone being evolved (compare chelidonic acid).—2. Heated by itself it splits up into  $CO_2$  and  $C_8H_8O_2$ , pyrocomane, a neutral substance, insol. water, [32°] (c. 213°).—3. Warmed with conc.  $NH_3$  it reacts thus (compare the behaviour of comenic and of oxy-comenic acids):  $C_8H_8O_2 + NH_3 = C_8H_8NO_2 + H_2O$ . The product is oxy-pyridine carboxylic (8-oxy-picolinic) acid  $C_8H_8N(OH)(CO_2H)$ .—4. When comanic acid (10 g.), hydroxylamine hydrochloride (6 g.),  $Na_2CO_3$  (4.5 g.) and water (100 g.) are warmed together, the sparingly soluble oximido- acid separates  $C_8H_8O(NOH) \cdot CO_2H$ . Crystallised from water, it forms crystals which decompose at 200°. With fuming HCl at 200° this forms  $C_8H_8NO_2$ , a crystalline body that is very soluble in water. The oximido- acid is reduced by Zn and HCl to oxy-pyridine carboxylic acid. From this it would appear that the oximido- acid is di-oxy-pyridine carboxylic (di-oxy-picolinic) acid (H. Ost, *J. pr.* [2] 29, 378).—5. Ethylamine converts comenic acid into oxy-ethyl-pyridine-carboxylic (oxy-ethyl-picolinic) acid,  $C_8H_8N(OH)(CO_2H)Et$ . This acid splits up at 160° into  $CO_2$  and (?) oxy-ethyl-pyridine.

**Salts.**— $BaA'$ , aq: v. sol. water.— $BaA'$ , 8aq.  $AgA'$ .

**Ethyl ether**  $EtA'$ . [103°]. Prisms; not acted upon by  $AcCl$ .

**Chloro-comenic acid**  $C_8H_8ClO_2$ . [247°]. Formed, together with the following, from comenic acid by successive treatment with  $PCl_5$  and water. Needles.

**Di-chloro-comenic acid**  $C_8H_8Cl_2O_2$ . [217°]. Needles (from alcohol).  $HI$  converts it into comenic acid.

**COMBINATION, CHEMICAL, LAWS OF.**—Chemistry concerns itself with the changes of composition and properties which certain definite kinds of matter undergo. Those kinds of matter which are studied in chemistry are divided into two classes, elements and compounds. Elements are those kinds of matter which undergo chemical change only by combining with other elements or compounds. Compounds may combine with other compounds or with elements, or they may be separated into two or more elements or compounds each unlike the others, and each weighing less than the original quantity of the compound used.

The expression 'homogeneous bodies' has sometimes been employed to denote elements and compounds, and to distinguish these from mixtures which palpably consist of unlike portions.

The law of the conservation of matter holds good in all chemical as in all physical, changes. This law may be stated as follows as regards chemical occurrences:—*When homogeneous bodies interact to produce new bodies, the sum of the masses of the bodies produced is equal to the sum of the masses of those which have interacted to produce them.*

The proof of this law is found in the whole body of chemical and physical science. A few numbers are here given, taken from the re-

searches of Stas, which were conducted with very great care and accuracy.

(1) Silver iodide is the sole product of the combination of iodine and silver; if the law of the conservation of mass holds good, the mass of silver iodide formed should be exactly equal to the sum of the masses of silver and iodine used.

Iodine used.	Silver used	Sum of Silver and Iodine.	Silver iodide formed.	Differences.
32-4665	27-6223	60-0888	60-086	-0028
46-8282	89-8405	86-6687	86-6653	-0034
44-7599	88-0795	82-8394	82-8375	-0019
160-2752	136-8548	296-6300	296-624	-0060
96-7964	82-8631	179-1595	179-159	-0005

The mass of silver iodide formed was in every case slightly less than the sum of the masses of silver and iodine used; but this is accounted for by the fact that it is impossible to collect absolutely the whole of the silver iodide formed. The differences amount to about  $\frac{1}{20,000}$  of the total weight, and fall within the limits of necessary experimental errors.

(2) In another series of experiments Stas heated silver iodate, and so decomposed it into silver iodide and oxygen; the differences between the mass of iodate used and the sum of the masses of iodide and oxygen obtained amounted to about  $\frac{1}{25,000}$  of the total weight. Here are a few of the results:—

Silver iodate	Silver iodide	Oxygen	Sum	Difference
98-2681	81-5880	16-6815	98-2695	+0014
156-7859	130-1755	26-6085	156-7840	-0019.

*Homogeneous bodies interact to produce new homogeneous bodies in certain definite and fixed ratios; there is a constant ratio between the masses of the interacting bodies, and also between the mass of each interacting body and the mass of the product, or of each of the products, of the change.*

The validity of this statement is assumed in all chemical investigations. Stas carried out a series of elaborate researches in order to determine whether the statement is or is not absolutely accurate. The following numbers taken from Stas' memoirs are illustrations of his results.

(1) Potassium chloride was caused to react with nitric acid to form potassium nitrate; the masses of potassium chloride and of potassium nitrate were determined.

Potassium chloride taken	Potassium nitrate formed	Potassium nitrate from 100 parts of chloride	Difference from mean
50-7165	68-6988	135-643	-002
80-2610	108-8665	135-638	-007
72-1032	99-8050	135-647	+002
50-2175	68-1200	135-649	+004
48-9274	68-3675	135-645	-000
69-8886	94-7900	135-640	-005
14-2578	19-3415	135-655	+010
		Mean 135-645	

The divergences from the mean are very small and are wholly accounted for by necessary experimental errors.

(2) A solution of silver was added to a solution of potassium bromide until the whole of the bromine was precipitated as silver bromide, and from the results was calculated the mass of potassium bromide which reacted with 100 parts by weight of silver. The numbers obtained established the absolute identity of the ratio of silver to potassium bromide in every experiment. Thus five experiments gave the following results:—

Potassium bromide	Silver	Potassium bromide reacting with 100 parts of silver	Difference from mean
9-20526	8-34305	110-332	-008
20-12315	18-23665	110-343	+003
15-8310	14-3451	110-357	+017
11-0618	10-0253	110-334	-006

The relations between the masses of interacting homogeneous bodies are expressed in the three laws of chemical combination, usually known as the law of fixity of composition, or the law of constant proportions; the law of multiple proportions; and the law of reciprocal proportions, or the law of combining weights. These laws may be stated in various forms of words; the following are fairly satisfactory.

*Law of constant proportions. The masses of the constituent elements of every compound stand in an unalterable ratio to each other, and also to the mass of the compound formed.*

*Law of multiple proportions. When two elements combine to form more than one compound, the masses of one of the elements which combine with a constant mass of the other element bear a simple relation to each other.*

*Law of reciprocal proportions; or law of combining weights. The masses of different elements which severally combine with one and the same mass of another element are also the masses of these different elements which combine with each other, or they bear a simple relation to these masses.*

When gaseous homogeneous bodies react to produce new gaseous bodies, the relations between the volumes of the interacting bodies and the volume of the product, or the volumes of the products, are expressed in the law of volumes or the law of Gay-Lussac.

*Law of volumes. When gaseous elements or compounds interact, the volumes of the interacting bodies bear a simple relation to each other, and also to the volumes of the gaseous products of the reaction.*

The law of constant proportions asserts the absolute invariability of the composition of every chemical compound. This law was finally gained as one result of the long controversy waged between Berthollet and Proust throughout the years 1801 to 1808. Many of the older chemists regarded every chemical compound as of fixed composition; the investigations of Bergmann

and Lavoisier, for instance, implicitly assumed the validity of this law of fixity of composition. Indeed, even so far back as the middle of the 17th century Van Helmont spoke of the saturation-point which is reached when a definite quantity of an acid is added to a specified quantity of a base. The experiments of Richter in the last years of the 18th century rendered it probable that the masses of two acids, which severally neutralise one and the same mass of a given base, bear a constant ratio to each other independently of the nature of the base with which they react.

Berthollet, in his *Essai de statique chimique*, published in 1803, stated the fundamental law of chemical action, to the effect that the amount of a chemical change is dependent on the affinities and the masses of the reacting bodies. One of the conclusions which he drew from this generalisation was, that the composition of the products of a chemical reaction may vary within certain limits, which are determined by the relative masses of the interacting bodies, and by the physical states of these bodies, and of those produced in the change. Proust opposed this notion of variability of composition. He analysed with great care many series of compounds, chiefly metallic oxides and sulphides, and as a final result he established the law of fixity of composition, or of constant proportion, on a firm basis of experimentally determined facts.

Proust admitted that two elements might combine in more than one ratio. Indeed he analysed various pairs of oxides and sulphides of the same metal; for instance, he gave the following analyses of oxides of copper and of tin:—

Copper oxides		Tin oxides	
(1)	(2)	(1)	(2)
Copper = 86.2	80	Tin = 87	78.4
Oxygen = 13.8	20	Oxygen = 13	21.6

\* Proust contented himself with stating the results of his analyses of compounds in percentages of the constituent elements. Had he calculated the masses of oxygen which were combined with the same mass of copper, or the same mass of tin, he might perhaps have forestalled Dalton and announced the law of multiple proportions. For Proust's analyses quoted above, if thus treated, give these results:—

Copper oxides		Tin oxides	
(1)	(2)	(1)	(2)
Copper = 86.2	86.2	Tin = 87	87
Oxygen = 13.8	21.5	Oxygen = 13	24

Dalton analysed two compounds of carbon and hydrogen, and found that the ratio of carbon to hydrogen in one compound was twice that of carbon to hydrogen in the other; in other words, he found that a fixed mass of hydrogen combined with a definite mass of carbon to form one compound, and with twice that mass of carbon to form another compound. Dalton did not conduct the experiments which led to this result, solely with the view of finding the quantitative laws of chemical combination, but rather with the object of rendering clear the atomic conception of chemical change which at this time was occupying his attention. While determining the composition of series of compounds, he had

always in his mind the conception of chemical combination as consisting in the union of extremely minute portions of the combining bodies. These minute portions, or atoms, of an element, he pictured to himself as chemically indivisible, and as all of the same mass; hence, he argued, if two elements combine to form more than one compound, the masses of one of these elements which combine with a fixed mass of the other element must bear a very simple relation to each other, one must be a whole multiple of the other, because portions of atoms cannot combine, and all the atoms of the same element have the same mass.

The law of multiple proportions was a necessary consequence of the Daltonian atomic theory. As a matter of fact, the law was deduced from experimental data by reasoning directed by the mechanical conceptions of this theory (v. *ATOMIC AND MOLECULAR WEIGHTS*, vol. i. pp. 336-7). Dalton's analyses were not very accurate. There can be little doubt that it was not the analytical results which led him to the discovery of the law of multiple proportions, but that the law was tentatively deduced from the atomic conception he had formed of chemical processes, and was then confirmed by the results of his analyses of compounds.

The announcement of the law of multiple proportions at once threw a flood of light on the empirical data already amassed regarding chemical composition; and it also led to more careful analyses of numerous compounds, by showing the importance of these analyses, and by interpreting their results in terms capable of general application.

After the publication of Dalton's *New System of Chemical Philosophy* in 1808, chemists everywhere busied themselves with making accurate analyses of compounds. Some chemists accepted the atomic theory of Dalton, others preferred to speak of combining proportions, or equivalents, rather than of atoms, of elements; but whether accepting or rejecting his theory, all were influenced by Dalton's teaching. The development of the atomic theory and the verification of the laws of chemical combination are indissolubly bound together.

If the atomic theory were granted, not only the law of multiple proportions, but also that of reciprocal proportions, followed as a necessary consequence. For the masses of two or more elements which combine with each other must be the masses, or whole multiples, or sub-multiples, of the masses, of those elements which severally combine with a fixed mass of some other specified element; because combination occurs between atoms, and atoms are chemically indivisible, and all the atoms of any element are of the same mass.

The outcome of the researches of Berzelius and his followers into the composition of compounds was to establish the laws of chemical combination on a firm basis; but so intimately were those investigations connected with the development of the atomic theory, and with the controversies which attended that development, that many chemists who demurred to the theory were inclined to deny the absolute validity of the laws as expressions of fact, and to think that these laws must stand or fall with the theory which had first given them importance.

The results of the laborious researches of Stas<sup>1</sup> have shown that the laws of chemical combination by mass are perfectly accurate statements of facts which hold good in all chemical processes.

Some of the results obtained by Stas have been already given (p. 236). The following analyses of silver chloride, and of ammonium chloride, prepared by different methods, serve to show that the composition of each of these two compounds at any rate is absolutely fixed:—

Method of preparation of silver chloride	Grams of silver chloride obtained from 100 of silver
1. Ag burnt in Cl gas	132.842
2. Ag dissolved in $\text{HNO}_3\text{Aq.}$ and ppd. by $\text{HCl}$ gas	132.847
3. Ag dissolved in $\text{HNO}_3\text{Aq.}$ and ppd. by $\text{HClAq.}$	132.848
4. Ag dissolved in $\text{HNO}_3\text{Aq.}$ and ppd. by $\text{NH}_4\text{ClAq.}$	132.842

The ammonium chloride analysed was prepared in four different ways:—

(1) Commercial salammontiac was dissolved in water and boiled with nitric acid to destroy organic matter; the liquid was decomposed by pure lime; the ammonia produced was led into water and then neutralised by hydrochloric acid; the ammonium chloride was sublimed in a stream of ammonia.

(2) Commercial sulphate of ammonia was heated with sulphuric acid, then boiled with nitric acid; the solution was treated in the same way as described in (1).

(3) A solution of potassium nitrite was mixed with potash, zinc-dust was added, and the liquid warmed; the nitrite was thus reduced to ammonia, which was led into water, and then neutralised by hydrochloric acid, the ammonium chloride was sublimed in an ammonia-stream.

(4) A part of the ammonium chloride prepared in (3) was sublimed *in vacuo*.

Weighed quantities of the different preparations were dissolved in water, and the quantity of silver required for the precipitation of all the chlorine was very accurately determined; experiments were conducted at different temperatures. A selection is given from the results:—

<sup>1</sup> *Recherches sur les rapports réciproques des poids atomiques* [1860]. *Nouvelles recherches sur les lois des proportions chimiques, sur les poids atomiques et leurs rapports mutuels* [1845]. A German translation of both memoirs was published in 1867, with the title *Untersuchungen über die Gesetze der chemischen Proportionen, über die Atomgewichte und ihre gegenseitigen Verhältnisse*.

One of the forms in which the law of reciprocal proportions may be stated is as follows: *The elements combine in the ratios of their combining weights, or in ratios which bear a simple relation to these.* By the combining weight of an element is here understood the smallest mass of that element which combines with unit mass of a standard element (*v. COMBINING WEIGHTS OR ELEMENTS*). Suppose the standard element were oxygen; then if the combining weight of an element were determined from analyses of different compounds of that element, all of which compounds contained oxygen, the law asserts either that the same value for the combining weight should be deduced from all the analyses, or that the different values found should bear a simple relation to each other. Stas proved the absolute accuracy of the law as regards silver, by determining the mass of this element combined with 16 parts by weight of oxygen in various compounds. The compounds chosen were, silver iodate, bromate, chlorate, and sulphate. Stas reduced these compounds to silver iodide, bromide, chloride, and sulphide, respectively, and then determined the amount of silver in these salts.

The following values were obtained for the mass of silver combined with iodine, &c., and 16 parts by weight of oxygen: (1) From analyses of iodide prepared by reducing iodate 107.928; (2) from analyses of bromide prepared by reducing bromate 107.921; (3) from analyses of chlorate prepared by reducing chloride 107.937; (4) from analyses of sulphide prepared by reducing sulphate 107.920. Stas further reduced potassium chlorate to chloride and then determined the mass of silver needed to precipitate the chlorine which was combined with 16 parts of oxygen in the original chlorate; he thus indirectly obtained a value for the combining weight of silver, meaning thereby the mass of this element which combines with that mass of chlorine which enters into union with 16 parts by weight of oxygen; the number found was 107.930. Another method which Stas used for testing the accuracy of the law of reciprocal proportions consisted in finding the ratio of the masses in which two elements united to form a binary compound, and also the ratio of the masses in which the same pair of elements were united in a compound formed by the addition of a third element to the first binary compound. Stas determined the ratio of silver to iodine in silver iodide and iodate, of silver to chlorine in silver chloride and chlorate, and of silver to bromine in silver bromide and bromate. The results proved the absolute accuracy of the law.

There can be no doubt as to the accuracy of the laws of chemical combination by weight. These laws are perfectly accurate statements of facts, and they hold good in every chemical change.

The law of combination of gaseous elements and compounds by volume, enunciated by Gay-Lussac, has not yet been subjected to so rigorous an examination as that which the laws of combination by weight have undergone.

The ratio of the volumes in which hydrogen and oxygen combine to form water was determined by Lavoisier, in 1783, to be 1:21.1. Other chemists stated the ratio to be approximately

2:1. In 1805 Gay-Lussac and Humboldt announced that the ratio was exactly 2:1, and in 1808 Gay-Lussac made the generalisation, which he based on numerous experiments, that the volumes of gaseous elements or compounds which combine to form gaseous products can be expressed by small whole numbers, and that the volume of the gaseous product of such combinations is either the sum of the volumes of the constituents or it bears a very simple relation ( $\frac{1}{2}$ ,  $\frac{1}{3}$ ,  $\frac{1}{4}$ , &c.) to this sum. Gay-Lussac's experiments showed, for instance, that 1 volume of nitrogen combines with 3 volumes of hydrogen to form 2 volumes of ammonia, and with 2 volumes of oxygen to form 2 volumes of nitrogen dioxide, &c.

Investigations have recently been made by Scott regarding the volumetric ratio in which hydrogen and oxygen combine to form water. The results (v. Scott, *Pr.* 1887, 398; *B.A.* 1887, 668; *N.* 37, 439) do not finally settle the ratio but they all tend to show that it is slightly less than 2:1, the most probable value being 1.997:1.

The laws of chemical combination are all included in the two statements:

1. The elements combine in the ratios of their combining weights, or in ratios which bear a simple relation to these.
2. The gaseous elements combine in the ratios of their combining volumes, or in ratios which bear a simple relation to these.

By *combining weight* is here meant the smallest mass of an element which combines with unit mass of some specified element taken as a standard; and by *combining volume* is meant the smallest volume of a gaseous element which combines with unit volume of some specified gaseous element taken as a standard.

The first statement has been simply verified by accurate experiments; the second does not yet stand on so firm an experimental basis.

**COMBINING WEIGHTS OF THE ELEMENTS.**—The laws of chemical combination by mass are expressed in the statement, *the elements combine in the ratios of their combining weights, or in ratios which bear a simple relation to these.* The term *combining weight* is here taken to mean the smallest mass of an element which combines with unit mass of a standard element. Hydrogen is adopted as the standard element; hence the practical definition of combining weight, as here understood, is the smallest mass of an element that combines with 1 part by weight of Hydrogen. But many elements do not combine with hydrogen; it is therefore often necessary to make use of some element other than hydrogen as a standard.

All the elements except fluorine and bromine form oxides, and most of the elements combine with chlorine. These two elements, oxygen and chlorine, are therefore frequently used as standards of reference in determinations of combining weights.

Oxygen combines with hydrogen in two ratios (by weight), 8:1 and 16:1; but chlorine

and hydrogen combine only in the ratio 35.5:1 (these values are given in round numbers). In accordance with the definition given above, the combining weight of oxygen is said to be 8, and the combining weight of chlorine to be 35.5. The combining weight of an element may then be taken to be the smallest mass of it which combines with 1 part by weight of hydrogen, or 8 parts by weight of oxygen, or 35.5 parts by weight of chlorine.

The same value is found for the combining weights of some elements which form both oxides and chlorides, whether the value is determined from analyses of the compounds with oxygen or with chlorine. Sodium and silicon are cases in point. But in some cases, one value is found for the combining weight of an element from analyses of its oxide, and another value from analyses of its chloride. Thus  $\text{I}_2^{\text{I}}$  is the smallest mass of iodine that combines with 35.5 parts by weight of chlorine, but  $\text{I}_2^{\text{II}}$  parts by weight of iodine combine with 8 parts of oxygen, and if the combining weight of iodine is deduced solely from analyses of its hydride, the value found is 127. So also, the smallest mass of nitrogen that combines with 1 part by weight of hydrogen is 4.66, but a compound of nitrogen and oxygen is known which is composed of 2.8 parts of nitrogen in union with 8 parts of oxygen.

Different values, then, are frequently obtained for the combining weight of an element according as the combining weight is determined in reference to hydrogen, chlorine, or oxygen, as the standard element. But the different values always bear a simple relation to each other. The following table presents the values found for the combining weights of a few elements; the ratios of the numbers are stated in the last column. Round numbers are given:—

	Combining weights referred to			Ratio of values
	H=1	O=8	Cl=35.5	
Nitrogen . .	4.6	2.8	4.6	5:3:5
Potassium . .	—	9.75	39	1:4
Copper . .	63.2	31.6	31.6	2:1:1
Arsenic . .	25	15	25	5:3:5

If, then, we define combining weight solely in terms of hydrogen, as unity, we can determine the combining weights only of a minority of the elements; if we admit the employment of oxygen and chlorine as standards of reference, we frequently arrive at different values for the combining weight of the same element. One primary object in determining combining weights is to find a basis for a system which shall represent the composition of compounds in formulae, by showing the number of combining weights of each element which are combined to form that quantity of a specified compound which is represented by its formula. In order to frame a satisfactory system of notation, some compromise must be come to as to the meaning to be given to the term combining weight. The difficulty may be partly overcome by adopting as the combining weight of an element the least common multiple of the numbers which express the masses of the element that severally combine with 1 part by weight of hydrogen, 8 parts of oxygen, and 35.5 parts of chlorine. For instance,

in the case of nitrogen, the L.C.M. of 2.8 and 4.66 is 14; and in the case of arsenic, the L.C.M. of 25 and 15 is 75.

The values thus obtained are usually adopted when it is desired to frame a fairly satisfactory definition for the term combining weight. These values are either the same as the atomic weights of the elements, or the latter are whole multiples of the former numbers. If a satisfactory and consistent system of notation is to be based on the combining weights of the elements, it is better to adopt for the combining weights values which are always identical with the atomic weights. The term combining weight of an element must then be taken to mean either the smallest whole number, or a whole multiple of the smallest whole number, divisible without remainder by each of the numbers that express the masses of the element which combine with 1 part by weight of hydrogen, 8 parts of oxygen, and 35.5 parts of chlorine, respectively. The following table exhibits the smallest masses of each element that combine with 1 part by weight of hydrogen, 8 parts of oxygen, and 35.5 parts of chlorine; it also shows the L.C.M. of these numbers, and the last column contains the whole number by which each L.C.M. must be multiplied in order to get the value used as the combining weight of the specified element in the ordinary chemical notation, which value is identical with the atomic weight of the element. (The values in the table in the next column are given in round numbers.)

The combining weight of an element is sometimes said to be the smallest mass of that element which enters into chemical combination with other elements, the smallest mass of hydrogen which combines chemically being taken as unity. But in order to give an exact meaning to the phrase, 'smallest relative mass of an element which enters into chemical combination with other elements,' it is necessary to add, 'to form a chemically reacting unit of a compound,' or some such expression as this. Now, the only conception of 'the chemically reacting unit of a compound' which has been put into an exact form capable of presentment in quantitative terms and of general application is that which arises from the application of the molecular and atomic theory to chemical occurrences; it is indeed the conception of the molecule. The definition of combining weight as 'the smallest relative mass of an element which enters into chemical combination with other elements' is essentially an atomic and molecular definition, although it is not couched in atomic and molecular language. For many years attempts were made to base a system of representing the composition of compounds on the combining weights of the elements without the help of the conceptions of atom and molecule. That mass of an element which combined with 1 part by weight of hydrogen, or 8 parts of oxygen, was sometimes taken as the combining weight of the element, and sometimes a multiple of this mass was proposed. But it was only when the atomic and molecular theory led the way that a satisfactory and consistent scheme of representing chemical composition was gained. The atomic weight of an element is always equal to, or is a whole multiple of, the least common multiple of the num-

bers that express the smallest masses of the element which combine with 1 part by weight of hydrogen, 8 parts of oxygen, and 35.5 parts of chlorine, respectively; the principles which guide chemists in their choice of the multiple are set forth in the article ATOMIC AND MOLECULAR WEIGHTS. If accurate values are to be found for the atomic weights of the elements, it is evident that the combining weights must be determined with the greatest care.

The exact definition to be given to the term combining weight is not a matter of paramount importance, for it is evident that whether we call the combining weight of an element the smallest mass of it which combines with 1 part by weight of hydrogen, or 8 parts of oxygen, or 35.5 parts of chlorine, or whether we say that the combining weight is the L.C.M. of these numbers, or whether we take the expression to mean a whole multiple of this L.C.M., in any case the law holds good that the elements combine in the ratios of their combining weights or in ratios which bear a simple relation to these. What is required to be determined with the greatest care and accuracy is the ratio between the combining masses of every element and hydrogen, oxygen, chlorine, or other standard element; because this ratio, taken in conjunction with the definitions of atom and molecule, determines the value of the atomic weight of the element, and on this value depend many of the chemical properties of the element. In connexion with this article v. the arts. ATOMIC AND MOLECULAR WEIGHTS; COMBINATION, CHEMICAL, LAWS OF; FORMULÆ; NOTATION.

M. M. P. M.

**COMBUSTION.**—Any manifestation of chemical energy attended by combination and accompanied by production of much heat is, strictly speaking, an instance of combustion. As commonly used, however, the term carries with it the idea of *incandescence*; that is, the reacting bodies are not merely *incalcescent*, but have their temperature raised to a point at which they emit light, or become self-luminous. This definition includes that of *inflammation*, which is, however, best restricted to instances of combustion in which the incandescent substances are gaseous. Such cases of combustion will be considered under **FLAME**.

All phenomena of burning are instances of combustion, and in the great majority of cases they consist in the union of the oxygen of the air with the substance which is being burnt, the visible signs of combustion, *i.e.*, the heat and light, being the result immediate or proximate of the chemical energy so expended.

It has been frequently observed that primitive communities regard as sacred all things that contribute to their existence or promote their well-being, and hence it is intelligible that a phenomenon so mysterious in its origin and process as fire, and at the same time so necessary to the welfare of mankind, should have been looked upon from the earliest times with particular reverence and awe. The evidence of fire worship is to be found probably in every religion. And it would be easy to show on strictly evolutionary principles how the idea of sanctity associated with the phenomenon of burning ramified and became interwoven into theories of the origin of life, of generation, and the nature of the soul and mind, and how it passed into the art of healing, and thence into the sciences which have sprung out of, or have been grafted on to, that art. The idea, but little shorn of its transcendental and spiritual attributes, is to be found in the earliest theories of chemistry. Fire plays such an important part in the operations of chemistry, the changes which it induces are so profound and extraordinary, burning and the evolution of heat by in-

trinsic agencies are so constantly witnessed as the result of chemical operations, that it is hardly surprising that the earlier chemists should have regarded combustion as the essential phenomenon of chemistry. A theory of combustion was to them also a theory of chemistry. Minds so sharply contrasted as those of Bacon and Boyle clearly apprehended the importance of a comprehensive theory of combustion from this point of view, but Bacon made no attempt to construct such a theory, and Boyle, in spite of his habitual caution, went singularly wrong in his efforts to explain the essential nature of fire and the phenomena we now recognise as due to oxidation. John Joachim Becher (1635-1682) has the credit of having first attempted to group all the facts of chemistry then known in such manner that they could be deduced from one general or universal principle. George Ernest Stahl (1660-1734) eagerly adopted Becher's fundamental idea, and amplified and worked it into a comprehensive system, capable of wide generalisation and fruitful of fresh lines of investigation. The theory of Becher and Stahl was essentially one of combustion. As it has exercised a very powerful influence on the development of chemistry, it may be desirable to sketch its main features with some degree of detail.

The theory as elaborated by Stahl is to be found in his *Fundamenta Chymia*, published in 1720, when its author was resident at Berlin as physician to the King of Prussia. It is not improbable that it was taught publicly at Halle between 1694 and 1716 when Stahl was Professor of Medicine at that University. Stahl defines chemistry as the art of resolving compounds into their constituents, and of recombining these constituents to again form the original or other compounds. According to Becher and Stahl, all combustible bodies are compounds, and in the act of burning they part with a constituent which is common to them all. This common principle was termed by Stahl *phlogiston* (*φλογιστος* = burnt). Bodies are combustible in proportion as they contain phlogiston; phosphorus, sulphur, charcoal, alcohol, sugar, the oils, resin, &c., are pre-eminently endowed with it. The metals also contain it, but in varying amount. When certain of the metals are strongly heated they are gradually converted into an earthy powder, termed a *calx*. The change which the metal had undergone was considered by Stahl as akin to ordinary combustion, and metals were regarded as compounds of calces, which were recognised as intrinsically dissimilar bodies, in union with the common principle, phlogiston, which was dissipated by the action of heat upon the metal. The re-conversion of the calx into the metal by processes which we now term reduction, that is by the action at a sufficiently high temperature of bodies like charcoal, coal, or by combustible gases, &c., was explained by Stahl as being due to the union of the phlogiston of the charcoal, &c., with the calx of the metal. It was noticed that many substances like phosphorus and sulphur on being burnt formed acids which when treated with a highly phlogisticated body such as charcoal gave rise to the original substances. Thus, phosphoric acid on being heated to a high tem-

perature with charcoal formed phosphorus again. Hence phosphorus was considered to be a compound of phosphoric acid and phlogiston; in the act of burning the phlogiston was disengaged and the acid left; on restoring phlogiston to the acid the phosphorus was regenerated. Stahl sought to demonstrate the identity of the combustible principle in all substances by pointing to the fact that the calx of lead, for example, could be converted into the metal by the employment of phlogisticated bodies of such widely different properties as charcoal, sulphur, flour, sugar, iron, &c. As only one substance, viz., lead, was formed by the action of each of these bodies, it seemed to follow that they must all contain a common principle. In the same way it was pointed out that phosphoric acid could be changed into phosphorus by the action of a great variety of combustible bodies, such as lamp-black, resin, sugar, or even the metals. Of course it was known that many substances existed which were incombustible and were not sensibly changed by the action of fire, as, for example, lime, clay, rocks, &c.; such bodies were regarded as dephlogisticated by the action of previous heat, or as being incapable of combining with phlogiston. As the doctrine of phlogiston extended, the ideas of the phlogistic school respecting its essential nature became more and more vague. There seems to be no doubt, however, that Stahl and his immediate followers, Neumann, Pott, and Margraaf, in Germany, and Réaumur, Duhamel, and Macquer, in France, regarded phlogiston as a definite substance possessing all the essential attributes of matter. Stahl himself appears to have considered that phlogiston, when isolated, would turn out to be a solid earthy body insoluble in water like charcoal, sulphur, phosphorus, bitumen, and the metals. Indeed, as so many highly phlogisticated bodies were insoluble in water, while their dephlogisticated constituents, e.g., phosphoric and sulphuric acids, were readily soluble, the property of solubility came to be regarded as dependent on or related to the presence or relative amount of phlogiston. Its presence or absence in fact affected all the properties of bodies, and caused all the changes they were capable of experiencing, as, for example, their relative stability, their capacity for union with other bodies, their acid or caustic characters, their colour, odour, and taste, and even their physiological and therapeutic activity. Many other natural phenomena, such as fermentation and decay, the growth of plants, and the processes of animal life, were also capable of explanation by the aid of the same general principle.

The doctrine of phlogiston was of incalculable service to chemistry. Indeed, it is not too much to say that Stahl's generalisation first raised chemistry to the dignity of a science. It not only served to present a simple and intelligible explanation of a mass of hitherto unconnected facts, but it pre-eminently fulfilled the function of every fruitful hypothesis by stimulating fresh inquiry and suggesting new lines of thought. Men like Black and Cavendish, whom we commonly reckon as phlogistians, were, however, not unimpaired of its weaknesses, and Black certainly recognised its inadequacy to explain facts which he knew to be incontrovertible, such,

for example, as the results obtained by Boyle on the calcination of metals. Boyle himself was doubtless aware of the doctrine in the form in which it was presented in Becher's *Physica Subterranea*, but it had probably no influence on his labours. Indeed he failed to perceive that much of his work was in direct opposition to Becher's teaching. His experiments on the calcination of lead and tin were interpreted by him as proving the materiality of heat, and it was reserved for Lavoisier and the so-called anti-phlogistic school of French chemists to point out their real significance.

The doctrine of phlogiston was paramount in chemistry for upwards of half a century: the discovery of nitrogen by Rutherford in 1772, and of oxygen by Priestley in 1774, and the fuller recognition of the functions of these bodies in the air, by paving the way towards a clearer apprehension of the nature of combustion, brought about the downfall of Stahl's generalisation. Geber, upwards of ten centuries ago, had supplied chemistry with facts respecting the nature of calcination which the long subsequent labours of Sulzbach, Cardan, Key, and Boyle had confirmed and strengthened. Hooke, in the *Micrographia*, and Mayow, in his *Opera Omnia Medicophysica*, pointed out that combustion consists in the union of something with the body which is being burnt, and Mayow, both by experiment and inference, demonstrated in the clearest way the analogy between respiration and combustion, and showed that in both processes one constituent only of the air is concerned; he distinctly stated that not only is there increase of weight attending the calcination of metals but that this increase is due to the absorption of the same *spiritus* from the air that is necessary to respiration and combustion. Mayow's experiments are so precise, and his facts so incontestable, that, as Chevreul has said, one is surprised that the truth was not fully recognised until a century after his researches. This recognition was forced upon the world by the experimental labours and writings of Lavoisier and his immediate followers in France. By repeating and extending the observations of Mayow, Black, Rutherford, and Priestley, Lavoisier proved that respiration, combustion, and calcination are essentially identical processes, in that they are primarily due to the action of oxygen—Priestley's dephlogisticated air—on the body undergoing change, and that the heat which is manifested is the result of the chemical change of which all these processes are examples. Lavoisier's experiments were so well devised and so admirably executed, his reasoning was so perspicuous and his proofs so irrefragable, that his conclusions seemed irresistible so far as the theory of combustion was concerned.

As Lavoisier's explanation of the true nature of combustion effected a complete revolution in the theory of chemistry, it may be desirable to trace the steps by which he was led to formulate it.

Lavoisier published in all some sixty memoirs, about half of which were concerned with the subject of combustion and of matters which immediately grew out of it. These appeared in different memoirs of the Academy between 1774 and 1788. It appears from his collected

memoirs, published after his death in 1794, that his earliest experiments on the cause of the augmentation of weight which bodies experience during combustion and calcination were made in 1772.

In a memoir published in 1774 Lavoisier described a repetition of Boyle's experiments on the calcination of tin, in which he showed that during the formation of the calx a portion of the air disappears, and that the tin increases in weight in amount equal to the loss of weight experienced by the air. Hence he concluded that a portion of air had united with the tin, and that the calx of tin is composed of tin and air.

There is nothing in this memoir nor in the note of 1772 to indicate that Lavoisier had any idea of the compound nature of air. Still it is evident that he had advanced beyond the position of Boyle and Rey. Boyle inferred that his experiments proved the materiality of heat, while Rey appears to have imagined that the absorbed air was merely entangled with the metal.

In the autumn of 1774 Priestley exhibited to Lavoisier his method of making oxygen gas from the calx of mercury. In the following year appeared Lavoisier's memoir *On the nature of the principle which combines with the metals during their calcination and which augments their weight*. Starting from the fact that many of the metallic calces can be reduced by charcoal with the production of a gas which is identical with that produced by burning charcoal in the air, Lavoisier concluded that carbonic acid gas contains an elastic principle which is common to the air and the metallic calx. In the case of the calx of mercury he could obtain this elastic principle by heat alone. The gas so obtained was identical with Priestley's dephlogisticated air. Lavoisier surmised that this gas, which he, like Priestley, found to be pre-eminently a supporter of combustion and respiration, was probably contained in nitre, inasmuch as this salt when heated with charcoal forms large quantities of carbonic acid gas. Mayow, on other grounds, had already made the same supposition. This memoir was followed in 1777 by that *On the combustion of phosphorus and the nature of the acid which results from that combustion*, in which Lavoisier first distinctly recognised that the air was composed of two distinct substances, one of which was absorbed by the burning phosphorus to the extent of one-fifth of the original volume of air, while the other, originally termed by him *mouffette atmosphérique*, was incapable of supporting combustion or animal life, and was not absorbable by metals when heated, and hence was not concerned in the process of calcination. In the same year he published a paper *On the combustion of candles in atmospherical air, and in air eminently respirable*, in which he demonstrates that the *mouffette atmosphérique*, or *azote* as it is now called, plays no part in the burning of the candle, but that the combustion is entirely due to the dephlogisticated air or oxygen. Although Lavoisier's theory of combustion and of calcination was now practically complete, and was fully developed by him in his memoir *On combustion in general* in 1778, it made comparatively little impression even in France, and gained no converts of note until 1785, when Berthollet and Fourcroy gave in their adhesion to

the new doctrine. The death-blow to phlogiston really came from the discovery of the compound nature of water. It was only after Cavendish's experiments on the combustion of hydrogen that Lavoisier was able to combat the generally received opinion as to the nature of the process of solution of metals in acids. It was observed that when certain metals were dissolved in acids, hydrogen was evolved, and the metals were converted into calces which could be again transformed into the metals by heating in hydrogen. These facts were accounted for by the Stahlian hypothesis on the assumption that the gas evolved on the solution of the metal was actually phlogiston, and that on heating the calx with the gas the phlogiston again combined with it to regenerate the metal. In 1783 Lavoisier was informed by Blagden, who at that time acted as Cavendish's assistant, of the experiments of the latter, made in 1781, on the production of water by the combustion of hydrogen. The importance of the discovery of the true chemical nature of water was at once perceived by Lavoisier. He and Laplace repeated Cavendish's experiment in presence of Le Roi and Blagden, and found that water was composed of 1 vol. of oxygen and 1.01 vol. of hydrogen. Further evidence of the compound nature of water was obtained by passing steam over red-hot iron contained in a porcelain tube, when free hydrogen was formed together with a calx of iron. Lavoisier was now able to explain the origin of the hydrogen in the act of solution of a metal in a dilute acid, on the assumption that in the process water was decomposed, and that the oxygen united with the metal to form the calx, while the hydrogen escaped in the free state. This view is further developed in the memoir *On the solution of the metals in acids*, published in 1785. Finally, in an elaborate paper *On Phlogiston*, Lavoisier connects together his various observations, elaborates his own theory of combustion, and confutes the phlogistic hypothesis.

Whatever may be thought of Lavoisier's claims to be considered the discoverer of oxygen, and of the true nature of air and water, there can be no question as to his merit in being the first to recognise the relation of these discoveries to the theory of combustion. As far back as 1779 he seems to have been fully persuaded of the insufficiency of the Stahlian hypothesis, and for upwards of a dozen years he laboured, practically alone, to demonstrate its insufficiency. His triumph was complete in 1785, and *La Chimie Française*, as the new doctrine was termed by Fourcroy, was embraced in France with all the fervour of revolution. Nor did national prejudice long delay its adoption in Germany and Great Britain. The Berlin Academy pronounced against phlogiston in 1792. Black early became a convert, but both Cavendish and Priestley, in spite of the fact that their discoveries had contributed so largely to its downfall, remained faithful to Stahl's doctrine to the end—an exemplification of the truth of Priestley's words that 'We may take a maxim so strongly for granted, that the plainest evidence of sense will not entirely change, and often hardly modify, our persuasions; and the more ingenious a man is, the more effectually he is entangled in his errors, his ingenuity only help-

ing him to deceive himself by evading the force of truth.'

T. E. T.

In connexion with Combustion v. OXIDATION and DROXIDATION.

COMENIC ACID v. DI-OXY-PYRIDINE CARBOXYLIC ACID.

OXY-COMENIC ACID v. TRI-OXY-PYRIDINE CARBOXYLIC ACID.

COMENIC ACID  $C_6H_5O_2$ . S. above 6 at  $100^\circ$ . Got by boiling meconic acid  $C_6H_5O_2$  with HCl,  $CO_2$  coming off. Purified by crystallising the difficultly soluble ammonium salt from water (How, *A.* 80, 65; *Ed. Phil. Trans.* 20 [2] 225; cf. Robiquet, *A. Ch.* [2] 51, 326; 53, 428; Liebig, *A.* 7, 287; 26, 116; Stenhouse, *P. M.* [3] 25, 196). Comenic acid is thrown down as a white powder when HCl is added to a solution of its ammonium salt.

**Properties.**—Prisms, laminæ, or granules; sol. boiling water, insol. alcohol. At  $260^\circ$  it splits up into  $CO_2$  and pyrocomenic acid.  $Fe_2Cl_6$  gives a red colour. Does not react with hydroxylamine (Odenheimer, *B.* 17, 2081).

**Reactions.**—1. *Sodium-amalgam* reduces it to syrupy hydrocomenic acid  $C_6H_5O_2$ , which forms a salt  $Ag_2C_6H_5O_2$  (v. Korff, *A.* 138, 191).—2. If comenic acid is boiled with  $PCl_5$  (4 equivalents) and  $POCl_3$  until no more HCl comes off, and the liquid distilled till the thermometer reaches  $160^\circ$ , an oil remains in the retort which is converted by boiling water into di-chloro-comenic acid,  $C_6H_2Cl_2O_2 \cdot CO_2H$  (yield, 20 p.c.). It crystallises from alcohol in needles, [ $217^\circ$ ]. Some chloro-comenic acid,  $C_6H_3ClO_2 \cdot CO_2H$ , [ $247^\circ$ ] is formed at the same time. Both acids are reduced by boiling conc. HI to comenic acid,  $C_6H_5O_2 \cdot CO_2H$  (g.v.). When comenic acid is boiled with aqueous  $NH_3$  it is converted into ( $\beta$ )-oxy-picolinic (oxy-pyridine carboxylic) acid. 3. Heated with  $PCl_5$  at  $280^\circ$  it gives  $C_6Cl_6$  or 'perchloro-mecylene,' and hexachloro-ethane. Perchloro-mecylene crystallises from alcohol in compact oblique prisms, melting at [ $39^\circ$ ] (Ost, *J. pr.* [2] 27, 294).—4. *Ethylamine* gives di-oxy-ethyl-pyridine carboxylic acid,  $C_6H_5EtN(OH) \cdot CO_2H$ .—5. *Aniline* gives similarly di-oxy-phenyl-pyridine carboxylic acid (H. Ost, *J. pr.* [2] 29, 380).

**Salts.**— $NH_4HA$  aq.: four-sided prisms; reddens litmus. V. sol. boiling water.— $K_2A$ : al. sol. water.— $KHA$ : short square needles; reddens litmus.— $NaHA$ : four-sided prisms (from hot water).— $BaA$  aq. (at  $121^\circ$ ).— $BaA$  5aq.: insol. boiling water.— $BaH_2A$  6aq.: sol. water.— $CaA$  aq. (at  $121^\circ$ ).— $CaA$  6aq.: prisms, insol. water.— $CaA$  8aq.— $CaHA$  7aq.: crystals, v. sol. hot water.— $MgA$  5aq.: crystalline grains.— $MgH_2A$  8aq.— $CuA$  aq. (at  $100^\circ$ ).— $Fe(OH)H_2A$  2aq. (at  $100^\circ$ ).— $PbA$  aq.— $AgHA$ : granular pp.— $Ag_2A$ : thick yellow pp.

**Ethyl ether**  $C_6H_5(OH) \cdot CO_2Et$ . [ $185^\circ$ ] (How); [ $127^\circ$ ] (Reibstein). From an alcoholic solution of the acid and HCl. Formed also by heating meconic acid with EtI and alcohol at  $100^\circ$ . Needles, v. sol. hot water. May be sublimed.  $Fe_2Cl_6$  gives a red colour. Very readily saponified. By successive treatment with sodium-amalgam and chloroformic ether a compound  $C_6H_5O_2$  [ $87^\circ$ ] may be got (Drechsel, *J. pr.* [2] 17, 164).

**Acetyl derivative of the ether**

$C_6H_5O_2(OAc)(CO_2Et)$ . [ $104^\circ$ ]. From the above and  $Ac_2O$  at  $450^\circ$  (Reibstein, *J. pr.* [2] 24, 277).

**Ethyl derivative**  $C_6H_5O_2(OEt)(CO_2H)$  [ $240^\circ$ ]. Obtained by fusing the ethyl derivative of meconic acid (g.v.) by itself. Crystallised from water, animal charcoal being used, it forms long white needles (Mennel, *J. pr.* [2] 26, 458).

**Salt.**— $Ag_2A$  2aq.: white needles.

**Amide**  $C_6H_5O_2(OH)(CO \cdot NH_2)$ . Formed by passing  $NH_3$  into an ethereal solution of ethyl comeniate. A pp. of  $C_6H_5O_2(OH)(CO_2Et)$  is first formed, but this is then slowly converted into  $C_6H_5O_2(OH)(CO \cdot NH_2)$ , whence HCl liberates the amide. White plates (from water). Not affected by boiling water. Boiling  $NaOH$  converts it into sodic comeniate. Its aqueous solutions give a red colour with  $Fe_2Cl_6$ .

**Salt.**— $C_6H_5O_2(OK)(CO \cdot NH_2)$  aq. Insol. alcohol.

**Chloro-comenic acid**

$C_6H_4ClO_2(CO_2H)(OH)$  1aq. Formed by passing Cl into water in which powdered comenic acid is suspended (How, *Ed. Phil. Trans.* 20 [2] 225). Four-sided prisms (from water). More soluble in water than comenic acid, v. e. sol. warm alcohol.— $Ag_2A$  (at  $100^\circ$ ).— $AgHA$  1aq.

**Bromo-comenic acid**  $C_6H_4BrO_2(CO_2H)(OH)$ .

Formed by the action of bromine-water on comenic or meconic acids. Four-sided prisms; less soluble than the preceding body. Boiling baryta-water gives oxy-comenic acid.— $AgHA$  (at  $100^\circ$ ).— $AgHA$  1aq.

**Ethyl ether**  $EtA$ . [ $141^\circ$ ]. From silver bromo-comeniate and EtI. Glittering needles (Mennel, *J. pr.* [2] 26, 472).

**Di-bromo-comenic acid**

$C_6H_3Br_2O_2(OBr)(CO_2H)$  (?).

**Formation.**—From Br and bromo-comenic acid.

**Preparation.**—Meconic acid (10 g.) is suspended in water (80 g.) and brothine (18 g.) is added. The product separates at once as crystalline plates (containing 3aq.).

**Properties.**—Its solution gives no colour with  $Fe_2Cl_6$  in the cold, a red colour appears on heating, bromo-comenic acid being formed. At  $105^\circ$  the crystals give off Br (2 mols.) and  $H_2O$ . An aqueous solution of the acid gives no pp. with  $BaCl_2$ , but on adding  $NH_3$  a red colour and an orange pp. are got. Zn and HCl reduce it to bromo-comenic acid.

**Constitution.**—This acid is not a true di-bromo-comenic acid, nor a compound of comenic or bromo-comenic acid with  $HBrO$ , hence it probably contains bromine in hydroxyl, although this is very unusual (Mennel, *J. pr.* [2] 26, 466).

**Ethyl ether**  $C_6H_3Br_2O_2(OBr)(CO_2Et)$ . From mono-ethylid meconate (10 g.), water (80 g.) and bromine (18 g.). Small yellowish tablets (containing 2aq.). Sol. water, alcohol, and ether. Readily decomposes. When heated with water or with  $SO_2$  it changes to white needles of bromo-comeniate of ethyl [ $141^\circ$ ] (v. *supra*).

**Nitro-comenic ether**  $C_6H(NO_2)(OH)CO_2Et$ . [ $147^\circ$ ]. From  $HNO_3$  (S.G. 1.5) and comenic ether in the cold. Better by passing  $N_2O$  into an ethereal solution of ethyl comeniate (B.). Sol. hot water, alcohol, and ether. Its aqueous solutions give with  $Fe_2Cl_6$  a red colouration.

**Salts.**— $C_6H(NO_2)(ONa)CO_2Et$ . Yellow needles. Explodes when heated.  $\rightarrow$   
 $\{C_6H(NO_2)CO_2Et\}_2O \cdot Ba$ . Explodes when heated. Silver salt blackens even when cold.

**Amido-comenic acid**  $C_6H(NH_2)O_4(OH)CO_2H$ . Formed by reduction of nitro-comenic ether by Sn and HCl (R.). Slender silky needles (containing aq) (from water). Sl. sol. alcohol and ether. Its aqueous solutions give a blue colour with a little  $Fe_2Cl_6$ , more  $Fe_2Cl_6$  turns the liquid red.

**Salt.**— $C_6H(NH_2)O_4(OH)CO_2H \cdot HCl$ , 3aq. Glittering scales, formed by adding conc. HCl to the above. Decomposed by water, losing HCl.

**Oxy-comenic acid**  $C_6HO_4(OH)CO_2H$ . From bromo-comenic acid by boiling baryta, or with HCl (R.). Also from comenamic acid,  $KMnO_4$ , and dilute  $H_2SO_4$ . Crystallises from water in long needles (with 3aq) or in short prisms (with aq). V. sol. water and alcohol, sl. sol. ether. In its aqueous solution  $Fe_2Cl_6$  gives a blue colour turned red by excess.  $NH_3$  at  $100^\circ$  gives tri-oxy-pyridine carboxylic acid.

**Salts.**— $C_6HO_4(OH)CO_2NH_4$ .—  
 $\{C_6HO_4(OH)CO_2\}_2Ba$ , 2aq.— $C_6HO_4(OK)CO_2K$ .

**Ethyl ether**  $C_6HO_4(HO)CO_2Et$ . [ $204^\circ$ ]. Small prisms (from alcohol).

**Di-acetyl derivative of the ether**  $C_6HO(OAc)_2CO_2Et$ . [ $75^\circ$ ]. Small needles (from alcohol).

**COMPOSITION, CHEMICAL.** By the chemical composition of a compound is meant, primarily, a statement of the masses of the elements by the combination of which a specified mass—say 100 parts—of the body has been produced, or into which a specified mass of the body may be resolved. So long as nothing more than the percentage elementary composition of compounds was determined, chemistry remained a collection of unclassified facts. The establishment of the law of multiple proportions, and the development of this law, and also that of combining weights, led to the possibility of assigning to each compound a certain number which expressed the smallest relative mass of it that entered into chemical reactions with other compounds; but no generally applicable method for determining the values of these chemically reacting masses was found until the help of the atomic and molecular theory had been sought (v. COMBINATION, CHEMICAL, LAWS OF; and COMBINING WEIGHTS OF ELEMENTS). The composition of the smallest chemically reacting mass is expressed by the formula of the compound, which tells the number of combining weights of each elementary constituent which have combined to form the mass in question. This wider meaning of chemical composition rests on, and arises from, the laws of chemical combination; but it became definite only when supplemented by atomic and molecular conceptions.

The atomic weights of all the elements have been determined with more or less accuracy; when the molecular weight of a compound is known, the chemical composition of that compound is expressed in a formula which states the number of atoms of each element that have combined to form a molecule of the compound (v. ATOMIC AND MOLECULAR WEIGHTS). In this further widening of the conception of chemical composition, the properties of a compound are

represented as determined by the nature and number of the atoms which form the molecule of the compound. This conception rests on, and arises from, the molecular and atomic theory.

It frequently happens, especially among compounds of carbon, that two or more compounds have the same composition and the same molecular weight, and yet differ in properties; such compounds are said to be isomeric. These differences in properties are generally regarded as associated with differences in the arrangement or configuration of the atoms which form the molecules of the compounds in question. More or less conventional methods are used for expressing the supposed relations between the properties of isomeric compounds and the structures of their molecules. These methods are based on the hypothesis of atomic valency which has arisen from the application of the molecular and atomic theory to the study of isomerism (v. EQUIVALENCY; FORMULE; ISOMERISM).

The term *chemical constitution* (q. v.) is often used to express that conception of chemical composition which includes an attempt to exhibit the properties of a compound as determined not only by the nature and number, but also by the relative arrangement, of the atoms which form the molecule of the compound.

In the preceding paragraphs it has been assumed that the composition of every element is always the same. As a matter of fact many bodies which were once regarded as elements have been proved to be compounds; and recent researches show that this process is likely to be repeated on some of those kinds of matter which are now classed among the elements. Be this however as it may, it is certain that some elements exhibit different properties when they are obtained from their compounds under different conditions. Phosphorus, carbon, oxygen, sulphur, and several other elements, exist in more than one form; they exhibit the phenomenon of allotropy. What we have learned of the connexions between properties and composition shows that these differences in properties are to be regarded as associated with differences in composition. The only consistent conception which can be formed at present of variations in the composition of elements is that which is furnished by the molecular and atomic theory. According to this conception, the properties of an element depend not only on the nature of its atoms, but also on the numbers of these atoms which are combined to form a molecule, and on the relative arrangement of the atoms in the molecule (v. ALLOTROPY, vol. i. p. 128).

M. M. P. M.

**COMPOUND RADICLES.** The study of chemical composition and properties has led to the conception that certain groups or collections of atoms in the molecules of various compounds remain so closely associated throughout chemical changes which the molecules undergo, that the functions performed by those groups of atoms in these reactions are practically identical with the functions performed by elementary atoms. Such groups of atoms are called *compound radicles* in distinction to the atom of an element which may be called a *simple radicle*. When two elements combine we may say that the compound is formed of two simple radicles;

e.g. NaCl is formed of the radicles Na and Cl; when two compounds combine to form what is generally called a *double compound* or a *double salt*, which double compound is easily resolved into the compounds by whose union it was formed, we may say that the double compound is formed of two compound radicles, each of which can be isolated. Similarly, when a compound goes through a series of reactions with the production of new compounds, all of which contain certain elements of the original compound, we may suppose that these certain elements were in some way closely associated in the original compound, and although we cannot isolate this group of elements, yet we may advantageously regard the original compound and those produced from it as formed by the union of this collocation of elementary atoms, or this compound radicle, with other atoms. The conception of the compound radicle is only a widening of the conception of the element; it is closely associated with the subjects of *chemical classification* and *chemical constitution* (q.v.). In connection with this subject v. RADICLE and TYPES, vol. iv.

M. M. P. M.

**CONCHIOLIN** v. PROTEIDS, *Appendix C.*

**CONCUSCONIDINE** v. CINCHONA BASES.

**CONCUSCONINE** v. CINCHONA BASES.

**CONNESSINE**  $C_{11}H_{19}N$ . [121½°]. Probably identical with *wrightine* (Stenhouse, *Ph.* [2] 6, 493; Haines, *Ph.* [2] 6, 432; Warnecke, *Ar. Ph.* [3] 26, 248, 281), which occurs in the bark and seeds of *Wrightia antidysenterica*, called *conessi bark*; occurs in the bark of *Holarrhena africana* (P. a. S.), and (though in much smaller quantity) in the East-Indian *H. antidysenterica* (Polstorff, *B.* 19, 1682). White silky needles. V. sol. alcohol, ether, benzene, and chloroform, v. sl. sol. water. Very bitter taste. Scarcely volatile with steam. Tertiary base.  $H_2SO_4$  and dilute  $KIO_4$  form oxy-conessine  $C_{10}H_{17}N_2O_4$  (?), a base which is coloured rose-red by conc.  $H_2SO_4$  at 100° (W.).

**Salts.**— $B^+HCl$  aq: small very soluble needles.  $B^+HNO_3$ : needles.— $B^+HCl$ — $B^+H_2Cl$ ,  $PtCl_2$  ½ aq: very sparingly soluble yellowish-red needles.— $B^+HClAuCl_2$  1½ aq: long yellow needles, v. sol. alcohol, nearly insol. water.— $B^+HCl$ ,  $AuCl_3$  3½ aq: golden-yellow needles.— $E^+HClHgCl_2$ : needles, sl. sol. water.

**Picrate**  $B^+C_6H_3(NO_2)_3OH$  aq: very slightly soluble glistening golden needles.

**Methylo-iodide**  $C_{11}H_{19}NMeI$  1½ aq: tables. V. e. sol. hot water.

**Ethylo-iodide**  $C_{11}H_{19}NEtI$  1½ aq: glistening tables.

**Methylo-hydroxide**  $C_{11}H_{19}NMe(OH)$ : strongly alkaline base formed by the action of  $Ag_2O$  upon the iodide. It readily absorbs  $CO_2$  forming the carbonate  $(C_{11}H_{19}NMeO)CO_2$  aq, which crystallises in long needles. On heating to c. 150° it splits up into conessine and  $MeOH$  (Polstorff & A. Schirmer, *B.* 19, 78).

**CONGLUTIN** v. PROTEIDS.

**CONGO-RED** v. *Amido-sulpho-naphthalene-azo-diphenyl-azo-naphthylamine sulphonic acid*, vol. i. p. 416.

**CONHYDEIN** v. CONINE.

**CONICEDLINE** v. CONINE.

**CONICRINE** v. CONINE.

**CONIFERIN**  $C_{10}H_{16}O_8$ . [185°]. S. (cold) 51.  $[\alpha]_D = -66$  that 20° (*B.* 18, 1600).

**Occurrence.**—1. In the cambium of coniferous trees (Kubel, *J. pr.* 97, 243).—2. In small quantity in beet-root, and hence it gives rise to traces of vanillin sometimes found in beet-sugar (Lippmann, *B.* 16, 44).—3. In asparagus (*B.* 18, 3335).

**Preparation.**—The juice of the cambial cells of fir trees is boiled, filtered, and evaporated to crystallisation.

**Properties.**—Satin needles (containing 2 aq). Efflorescent in dry air. V. sol. hot water, sl. sol. alcohol, insol. ether. Levorotatory. Somewhat bitter. Its aqueous solution is not pptd. by metallic salts. Boiling dilute  $H_2SO_4$  splits it up into glucose and a resin. Conc.  $H_2SO_4$  gives a dark violet colour, and, on adding water, an indigo-blue pp. It is hydrolysed by emulsin into glucose and coniferyl alcohol. Phenol and  $H_2SO_4$  give a blue colour, especially in sunlight. A dilute alcoholic solution of thymol and  $KClO_4$  turns coniferin moistened with  $H_2SO_4$  blue (Molisch, *C. C.* 1887, 366). Chromic mixture oxidises it to vanillin, giving the odour of vanilla (Tiemann). In weak alkaline solution sodium amalgam reduces it to eugenol (L. Chiozza, *C. C.* 1888, 443).

**Tetra-acetyl derivative**  $C_{14}H_{18}Ac_4O_8$ . [126°]. From coniferin and  $Ac_2O$  (Tiemann & Nagai, *B.* 8, 1140). Crystalline. Insol. cold water, m. sol. cold alcohol and ether.

**CONIFERYL ALCOHOL**  $C_{10}H_{16}O_2$  i.e.  $C_6H_5(OH)(OMe)(C_4H_9OH)$ . [4:3:1]. [74°]. Formed by subjecting an aqueous solution of coniferin to the action of emulsin at 25°:  $C_{10}H_{16}O_8 + H_2O = C_6H_5O_2 + C_4H_9O_2$  (Tiemann & Haarmann, *B.* 7, 611). Prisms. Sl. sol. hot water, m. sol. alcohol, v. sol. ether. Sol. alkalis and reppd. by acids in an anorthous condition, which softens at 160° and is v. sl. sol. alcohol and ether. This amorphous form is coloured red by conc.  $H_2SO_4$ , and afterwards dissolved with a red colour. Chromic acid mixture produces vanillin, which may be recognised by its characteristic odour; the other products of oxidation are HOAc and aldehyde. Potash-fusion gives protocatechuic acid. Sodium amalgam reduces it to eugenol  $C_{10}H_{12}O_2$ .

**CONIINE**  $C_8H_{17}N$  i.e.  $C_4H_9PrN$  or

*Dextro*-( $\alpha$ )-propyl-piperidine.

Mol. w. 127. (169°). S.G. 1.846 (Petit, *B.* 10, 896); 886 (Schorm). S. (cold) 1:11. S. (ether) 17.  $[\alpha]_D = 13.8$ .

**Occurrence.**—In all parts of the hemlock (*Conium maculatum*) (Giesecke, Brande's *Ar. Ph.* 20, 97; Geiger, *Mag. Pharm.* 35, 72, 259; 36, 159; v. Planta a. Kekulé, *A.* 89, 129).

**Synthesis.**—( $\alpha$ )-Allyl-pyridine (from ( $\alpha$ )-picoline and paraldehyde) on reduction with sodium and alcohol gives ( $\alpha$ )-propyl-pyridine hexahydrate; this ( $\alpha$ )-propyl-piperidine is identical in all its properties with coniine, except that it is optically inactive, but by means of the acid tartrate it can be separated into a dextro- and a

levo-base, the former of which is identical with natural coniine (Ladenburg, *B.* 19, 2579).

**Formation.**—1. By heating conhydrine with HI and phosphorus, and treating the resulting hydride of iodo-coniine with tin and HCl (Hofmann, *B.* 18, 5).—2. By reducing (α)-coniine with HI and P (Hofmann).

**Preparation.**—100 kilos. of hemlock seeds, after soaking in hot water till swollen, are mixed with a solution of 4 kilos. of Na<sub>2</sub>CO<sub>3</sub> in 4 litres of water, and the mixture distilled with steam of about 3 atmospheres. The aqueous distillate is neutralised with HCl evaporated, NaOH added and extracted with ether. The residue after distilling off the ether is fractionated. Another method consists in extracting the ground seeds *in vacuo* with dilute acetic acid, evaporating the solution to a syrup *in vacuo*, adding magnesia, and extracting with ether (Schorm, *B.* 14, 1765; cf. Wertheim, *A.* 100, 328; 123, 157).

**Properties.**—Oil, smelling like mice. Is a violent paralytic poison which acts on the motor nerves (Hofmann, *B.* 14, 705; cf. Christison, *J. Ph.* 22, 413; *J. Chim. Med.* 12, 461; Kuhlmann, *N. Br. Arch.* 32, 38). For white mice the lethal dose is 0.758 g. per kilo., whilst 0.750 g. does not produce death (Ladenburg). Its aqueous solution becomes turbid on warming. Volatile with steam. Alkaline to moist test-papers. Coniine (100 pts.) dissolves water (25 to 80 pts.) and the solution when heated becomes turbid from separation of water. V. sol. alcohol, ether, chloroform, benzene, amyl alcohol, and acetone; sl. sol. CS<sub>2</sub>. Coniine dissolves S but not P. Coniine gives a yellow pp. with phosphomolybdic acid, a cheesy pp. with potassio-mercuric iodide, and an orange pp. with potassio-bismuthic iodide. If coniine is dropped into a solution of alloxan, an intense-purple red colour is gradually developed, while white needles separate, which dissolve in cold KOH aq forming a purple solution (Schwarzenbach, cf. W. Blyth, *Poisons*, 1884, p. 251). Chloride of iodine gives a dark yellow pp. Coniine does not dissolve CaCl<sub>2</sub>.

**Estimation.**—Cripps, *Ph.* [3] 18, 511.

**Reactions.**—1. *Oxidises* readily in the air, becoming brown.—2. Boiling *chromic mixture* evolves *n*-butyric acid (Blyth; Grünzweig, *A.* 162, 193).—3. Alcoholic solution of *iodine* forms a dark brown pp. which afterwards disappears, the liquid becoming colourless.—4. *Dromine* forms a mass of needles [c. 100°]; if too much bromine is used a gummy mass is formed (Blyth).—5. *Chlorine* gas produces a turbidity in moist coniine.—6. Nitrous acid gas produces 'azoonhydrine' C<sub>8</sub>H<sub>17</sub>N<sub>2</sub>O (Wertheim, *A.* 123, 157).—7. By prolonged treatment with HI coniine is reduced to octane and NH<sub>3</sub> (Hofmann, *B.* 18, 5).—8. By distillation with *sine dust* it loses hydrogen and is converted into propylpyridine (congrine) (Hofmann, *B.* 17, 825).—9. By the action of *bromine in alkaline solution* it gives a very unstable bromo-derivative which probably has the formula C<sub>8</sub>H<sub>17</sub>NBr. If this bromo-derivative is treated with H<sub>2</sub>SO<sub>4</sub> it yields (α)-coniine C<sub>8</sub>H<sub>17</sub>N with splitting off of HBr. If however the elimination of HBr from the bromo-derivative is produced by treating it with alkalis (γ)-coniine is obtained (Hofmann, *B.* 18, 109).—10. Reacts with *aldehydes* thus:

2C<sub>8</sub>H<sub>17</sub>NH + CH<sub>3</sub>.CHO = (C<sub>8</sub>H<sub>17</sub>N)<sub>2</sub>.OH.CH<sub>3</sub> + H<sub>2</sub>O &c. (Schiff, *B.* 6, 143).—11. *Chloroformic ether* forms C<sub>8</sub>H<sub>17</sub>N.CO<sub>2</sub>Et (245°). This is an oil, lighter than water, and very stable (Schotten, *B.* 15, 1947).—12. *Phenyl cyanate* forms the anilide of the same coniine *ν*-carboxylic acid C<sub>8</sub>H<sub>17</sub>N.CO.NHPh, which is v. sol. alcohol, ether, and benzene (Gebhardt, *B.* 17, 8041).—13. *Phenyl thiocarbimide* forms C<sub>8</sub>H<sub>17</sub>N.CS.NHPh [88°] (G.).—14. *Phthalic anhydride* forms CO<sub>2</sub>H.C<sub>8</sub>H<sub>17</sub>.CO.NC.C<sub>6</sub>H<sub>4</sub> [155°] the coniine salt of which when heated at 210° gives amorphous C<sub>8</sub>H<sub>17</sub>.C<sub>6</sub>H<sub>4</sub>.O<sub>2</sub>.(NC<sub>6</sub>H<sub>4</sub>)<sub>2</sub> (Pintti, *G.* 13, 558; *A.* 227, 181).

**Salts.**—B'HCl: [218°]. Colourless deliquescent laminae. Dry HCl is said to colour dry coniine blue.—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>4</sub>: orange crystalline powder.—B'HBz: [100°] (Mourrut, *Ph.* [3] 7, 23). Trimetric needles; *a:b:c* = 8876:1:4218.—B'HI: flat monoclinic prisms; *a:b:c* = 1.2112:1:1.532 (Schorm, *B.* 14, 1765).—B'HI<sub>2</sub>: octahedra (Baur, *Ar. Ph.* [3] 5, 214).—Oxalate B'<sub>2</sub>H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>: small crystals.—Tartrate B'C<sub>4</sub>H<sub>4</sub>O<sub>6</sub> 2aq: large trimetric crystals; *a:b:c* = 7766:1:5859.

**Combination.**—B'<sub>2</sub>H<sub>2</sub>GCl<sub>2</sub>: lemon-yellow pp. (Blyth).—B'<sub>2</sub>H<sub>2</sub>S (?). Unstable (Schmidt, *B.* 7, 1525).

**Benzoyl derivative** C<sub>8</sub>H<sub>17</sub>NBz. Thick oil. On oxidation with KMnO<sub>4</sub> it yields the benzoyl-derivative of homo-coniine acid—C<sub>8</sub>H<sub>17</sub>NBzCO<sub>2</sub>H (Schotten a. Baum, *B.* 17, 2543).

**Nitrosamine** C<sub>8</sub>H<sub>17</sub>N.NO. *Asoonhydrine*. (150°–160°). From coniine by treatment with nitrous acid gas, followed by water (Wertheim, *A.* 123, 157; 130, 269). Yellow oil. V. sol. alcohol and ether. HCl passed into its ethereal solution reproduces coniine, giving off N and NO; zinc and HCl do the same.

**Methyl-coniine** C<sub>8</sub>H<sub>17</sub>NMe. From coniine and MeI. Formed also, together with C<sub>8</sub>H<sub>17</sub> and H<sub>2</sub>O, by distilling its ethylohydride (Kekulé a. Planta, *A.* 89, 143). **Liquid.**

**Ethylo-hydroxide** C<sub>8</sub>H<sub>17</sub>NMeEtOH. From the preceding by successive treatment with EtI and moist Ag<sub>2</sub>O (K. a. P.). Strongly alkaline base.—C<sub>8</sub>H<sub>17</sub>NMeEtI: crystalline powder, not affected by aqueous KOH.—C<sub>8</sub>H<sub>17</sub>NMeEtCl<sub>3</sub>HgCl<sub>2</sub>.—(C<sub>8</sub>H<sub>17</sub>NMeEtCl)<sub>2</sub>.PtCl<sub>4</sub>: yellow octahedra.—C<sub>8</sub>H<sub>17</sub>NMeEtAnCl<sub>4</sub>.

**Methylo-hydroxide** C<sub>8</sub>H<sub>17</sub>NMe<sub>2</sub>OH. From coniine by treatment with excess of MeI, the resulting iodide being decomposed by moist Ag<sub>2</sub>O.

**Di-methyl-coniine** (C<sub>8</sub>H<sub>17</sub>Me)<sub>2</sub>NMe. (182°). Prepared by the dry distillation of the methylo-hydroxide of methyl-coniine. **Liquid.**—(B'HCN).PtCl<sub>4</sub>: sparingly soluble needles.

**Methylo-iodide** C<sub>8</sub>H<sub>17</sub>MeNMeI: crystalline solid.

**Methylo-hydroxide** C<sub>8</sub>H<sub>17</sub>MeNMe<sub>2</sub>OH: on dry distillation it splits up into H<sub>2</sub>O, CH<sub>3</sub>OH, NMe<sub>3</sub>, di-methyl-coniine, and conylene (C<sub>8</sub>H<sub>17</sub>) (Hofmann, *B.* 14, 708).

**Ethyl-coniine** C<sub>8</sub>H<sub>17</sub>NEt. From coniine and EtI, the resulting C<sub>8</sub>H<sub>17</sub>NEtHI being decomposed by KOH (K. a. P.). Oil, smelling like mice.—(C<sub>8</sub>H<sub>17</sub>NEt)<sub>2</sub>H<sub>2</sub>PtCl<sub>4</sub>: yellow crystalline powder.

**Ethylo-iodide** C<sub>8</sub>H<sub>17</sub>NEtI. **Crystalline mass.** Gives (C<sub>8</sub>H<sub>17</sub>NEtCl)<sub>2</sub>.PtCl<sub>4</sub>.

## CONIINE.

**Oxy-ethyl coniine**  $C_8H_{17}N.OH$ . (241°). The hydrochloride is formed by the action of glycol chlorhydrin on coniine.

### *Benzoyl derivative*

$C_8H_{17}N.CH_2CH_2OBr$ . From  $BzCl$  and the above.— $B'HI$ : small pearly plates.— $B'HCi$ : very soluble crystals (Ladenburg, *B.* 14, 2409; 15, 1144).

**Tri-bromo-oxy-coniine**  $C_8H_{17}Br_3ON$ . Obtained as a by-product in the preparation of ( $\gamma$ )-coniceine by treatment of coniine with bromine and alkali. Formed by the action of bromine and alkali upon ( $\gamma$ )-coniceine (Hofmann, *B.* 18, 121). Heavy oil. Very unstable. The free base quickly decomposes spontaneously into the hydrobromide and di-bromo-oxy-coniceine  $2C_8H_{17}Br_2ON = C_8H_{17}Br_3ON.HBr + C_8H_{17}Br_2ON$ . On reduction with tin and  $HCl$  it gives coniine and ( $\gamma$ )-coniceine.

**Salts.**— $B'HB$ : needles.— $B'HNO_3$ : very sparingly soluble.— $B'H_2Cl_2PtCl_4$ : nearly insol. yellow crystalline pp.— $B'HCiAuCl_4$ : crystalline solid.

**Di-methyl-oxy-coniine**  $C_8H_{17}Me_2ON$ . (226°). Formed by the dry-distillation of the hydroxide of the ammonium-base  $C_8H_{17}MeON.MeOH$ , the iodide of which was obtained by digesting ( $\gamma$ )-coniceine with methyl iodide and alcoholic  $NaOH$  (Hofmann, *B.* 18, 117). Colourless liquid. Sl. sol. water. Strongly alkaline.— $B'HCiAuCl_4$ : sparingly soluble crystals.

**Homo-coniic acid**  $C_8H_{17}O.N$  i.e.  $CH_3CH_2CH_2CH_2CH(NH_2)CH_2CH_2CO_2H$  (?). (158°). Obtained by saponification of the benzoyl derivative (Baum, *B.* 19, 502). White crystals; v. sol. water and alcohol. The aqueous solution reacts neutral. Optically inactive. Is not poisonous. It readily loses  $H_2O$  and is converted into the inner-anhydride. When treated with nitrous acid it evolves nitrogen.

**Benzoyl derivative**  $C_8H_{17}NBz.CO.H$ . (143°). Formed by oxidation of benzoyl-coniine with  $KMnO_4$  (Schotten a. Baum, *B.* 17, 2549). Needles or prisms; sol. alcohol, nearly insol. water and ether.— $A'Ag$ : nearly insoluble white amorphous pp.— $A'Cu$ : blue amorphous pp.; sl. sol. hot water, insol. alcohol.

**Ethyl ether**  $C_8H_{17}NBz.CO.Et$ . (95°). Long white flat prisms; v. sol. alcohol, ether, &c., nearly insol. water and petroleum-ether (Baum, *B.* 19, 500).

**Inner anhydride**  $C_8H_{17}ON$ . (85°). Readily formed by splitting off  $H_2O$  from the acid by heating it to its melting-point, treating it with absolute alcohol, &c. (B.). White crystals. V. sol. water, alcohol, ether, and chloroform; m. sol. petroleum-ether. Sublimable. It is reconverted into the acid by boiling with baryta-water and ppg. the Ba with  $CO_2$ .

( $\alpha$ )-Coniceine  $C_8H_{17}N$ . [ $\alpha$ . -16°]. (158°). V.D. -4.81 (obs.). S.G. 15-893.

**Formation.**—1. Together with ( $\beta$ )-coniceine, by heating conhydrine  $C_8H_{17}ON$  with  $P_2O_5$ .—2. Together with the ( $\beta$ )-coniceine, by heating conhydrine with  $HCl$ .—3. By the action of  $H_2SO_4$  on the bromo-derivative  $C_8H_{17}NBr$  obtained by treating coniine with bromine and  $NaOH$ . The yield is 40 p.c. of the coniine.—4. Together with ( $\beta$ )-coniceine, by heating iodo-coniine  $C_8H_{17}IN$ .

**Properties.**—Colourless liquid. Sl. sol. water.

Its odour is extremely like that of coniine. Tertiary base of strongly alkaline reaction. Its physiological action resembles that of coniine, but it is about five or six times as poisonous. By  $HI$  and  $P$  it is reduced to coniine.

**Salts.**— $B'HCi$ : six-sided tables.— $B'H_2Cl_2PtCl_4$ : large yellow trimetric prisms.— $B'HCiAuCl_4$ : yellow needles.—Picrate  $B'C_6H_4(NO_2)_3OH$  (225°): yellow needles; sl. sol. cold alcohol, nearly insol. water.

**Methylo-iodide**  $B'MeI$ : crystalline solid; very sol. water and alcohol.—( $B'MeCl$ ),  $PtCl_4$ : yellow pp. (Hofmann, *B.* 18, 8).

( $\beta$ )-Coniceine  $C_8H_{17}N$ . (41°). (168°). Formed together with ( $\alpha$ )-coniceine (1) by heating conhydrine  $C_8H_{17}ON$  with  $P_2O_5$ , (2) by heating conhydrine with fuming  $HCl$ , (3) by heating iodo-coniine  $C_8H_{17}IN$  above 100°. Colourless needles. Very volatile. Coniine-like odour. Secondary base of strongly alkaline reaction. Weaker poison than the ( $\alpha$ )-coniceine.

**Salts.**— $B'HCi$ : colourless, very soluble prisms.— $B'HCiAuCl_4$ .

( $\gamma$ )-Coniceine  $C_8H_{17}N$ . (173°). Obtained by the action of aqueous alkali upon the bromo-derivative  $C_8H_{17}NBr$  formed by treatment of coniine with bromine in alkaline solution; the yield is 30 p.c. of the coniine. Colourless liquid. Not solid at -50°. Volatile with steam. About 12 times more poisonous than coniine. Sl. sol. water. Strongly alkaline. Lighter than water. Secondary base. By further treatment with bromine and alkali it is converted into tri-bromo-oxy-coniine  $C_8H_{17}Br_3ON$ . By digesting with methyl-iodide and alcoholic  $NaOH$  it yields the methylo-iodide of oxy-di-methylo-coniine  $C_8H_{17}Me_2ONMeI$ .

**Salts.**— $B'H_2Cl_2PtCl_4$ : large crystals; S (at 20°) 2.4.— $B'HCiAuCl_4$ : sparingly soluble crystals.— $B'H_2Cl_2SnCl_4$ : large crystals, the most characteristic salt of the base.

**Acetyl derivative**  $C_8H_{17}NAc$  (252°-255°); oil (Hofmann, *B.* 18, 111).

**Oxy-coniceine**  $C_8H_{17}ON$  (210°-220°). Formed by reduction of di-bromo-oxy-coniceine with tin and  $HCl$  (Hofmann, *B.* 18, 125). Colourless fluid. Volatile with steam. By digestion with alcoholic  $KOH$  it loses  $H_2O$  and is converted into coniceidine  $C_8H_{17}N$ .

**Salts.**— $B'HCi$ : colourless needles.— $B'HCiAuCl_4$ : easily soluble thick needles. The stannic double chloride is sparingly soluble.

**Di-bromo-oxy-coniceine**  $C_8H_{17}Br_2ON$ . Formed by spontaneous decomposition of tri-bromo-oxy-coniine, thus:  $2C_8H_{17}Br_3ON = C_8H_{17}Br_2ON.HBr + C_8H_{17}Br_3ON$ . Prepared by shaking the tri-bromo-oxy-coniine hydrobromide with aqueous  $NaOH$  and ether. By tin and  $HCl$  it is reduced to oxy-coniceine (Hofmann, *B.* 18, 124).

**Coniceidine**  $C_8H_{17}N$ . (56°). (above 300°). Colourless needles. Sol. alcohol and ether. Formed by elimination of  $H_2O$  from oxy-coniceine by digesting it with alcoholic  $KOH$ .

**Salts.**— $B'HCi$ : small sparingly soluble tables.— $B'H_2Cl_2PtCl_4$ : nearly insoluble needles (Hofmann, *B.* 18, 126).

**Conhydrine**  $C_8H_{17}NO$ . *Oxy-coniine*. (121°). (225°) at 720 mm. Accompanies coniine in hemlock seeds (Wertheim, *Sitz. W.* 47 [2] 299). Glistening plates (from ether). M. sol. water, v. sol.

alcohol and ether. Alkaline. Does not react with nitrous acid. Is a weak narcotic poison.

**Reactions.**—1. By the action of  $P_2O_5$ , it is not converted, as Wertheim (*A.* 127, 75) supposed, into coniine, but into a mixture of ( $\alpha$ )- and ( $\beta$ )-coniine  $C_8H_{17}N$ . These products are also formed by heating conhydrine with strong HCl (Hofmann, *B.* 18, 5).—2. By heating with HI and P it is converted into an iodo-coniine  $C_8H_{16}IN$ , which on heating above  $100^\circ$  is converted into the hydroiodides of ( $\alpha$ )- and ( $\beta$ )-coniine, and is reduced by  $Sn$  and HCl to coniine.—3.  $PBr_3$  converts it into a bromo-coniine  $C_8H_{16}BrN$ .

**Salt.**— $B'_2H_2PtCl_6$ : red crystals. The sulphate is also crystalline.

**Ethyl-conhydrine**  $C_8H_{17}EtNO$ . Formed by the action of KOH on the crystalline compound of conhydrine with  $EtI$ . Oil.

**Ethyl-iodide**  $C_8H_{17}EtNOEtI$ . Trimetric crystals;  $a:b:c = .8823:1:1.05$  (Zepharovich, *Sitz. W.* 47 [1] 275). Converted by  $Ag_2O$  into a caustic ethyl-hydroxide, whence HCl and  $PtCl_4$  give  $(C_8H_{17}EtNOEtCl)_2PtCl_4$ : dimetric crystals;  $a:c = 1:870$ .

**Paraconiine**  $C_8H_{17}N$ . *Paraconiine*. Mol. w. 125. (169°). S.G.  $d_{20}^{20} = .913$ ;  $d_{20}^{20} = .842$ .

**Formation.**—1. By heating butyric aldehyde with alcoholic  $NH_3$  and distilling the resulting dibutyraldine (Schiff, *A.* 157, 352; 166, 88; *B.* 5, 42).—2. From butylidene chloride  $CH_3CH_2CH_2CHCl_2$  (or bromide) and alcoholic  $NH_3$  at  $180^\circ$  (Michael and Gundelach, *Am.* 2, 172; *B.* 14, 2105).

**Properties.**—Yellow liquid, smelling like coniine. V. sol. alcohol and ether; sl. sol. water. The aqueous solution becomes turbid when warmed. Inactive. As poisonous as coniine. Chlorine water produces in the aqueous solution a white pp., sol. HCl. The hydrochloride, when evaporated, becomes violet. Iodine dissolved in  $KI$  gives a brown pp. Is a tertiary base— $B'_2H_2PtCl_6$ : orange crystals.

**Paradiconiine**  $C_{16}H_{33}N$ . (210°). S.G.  $d_{20}^{20} = .915$ . Formed, together with paraconiine, by the prolonged action of alcoholic  $NH_3$  on butyric aldehyde. Its salts are amorphous.

**CONIMENE**  $C_{15}H_{27}$ . (264°). An essential oil obtained by steam-distillation from conima or incense-resin (called also Gum Hyawa), the produce of *Icica heptaphylla* (Stenhouse and Groves, *C. J.* 29, 175).

**CONQUINAMINE** v. CINCHONA BASES.

**CONQUINENE** v. CINCHONA BASES.

**CONQUININE** v. CINCHONA BASES.

**CONSTITUTION, CHEMICAL** (cf. COMPOSITION, CHEMICAL).—The conception of chemical constitution is a development of that of chemical combination. All our present notions on the subject of constitution are essentially molecular and atomic. We cannot, indeed, express our conceptions of chemical constitution without using the language of the molecular theory. The chemical molecule is regarded as a definite structure built up of atoms, or groups of atoms, which are related to one another in a definite, although as yet unknown, way. The properties of the molecule are regarded as conditioned by the nature and number of the atoms, and also by the relations between the atoms, which form the molecule. Our only method of expressing the relations which undoubtedly exist between

the parts of molecules is based on supposing these relations to be essentially space-relations. We try to picture the molecule as a configuration of parts, each of which bears a definite space-relation to each other, while all are capable of performing regulated motions without the disruption of the molecule.

This conception of the molecule as a structure is developed in the hypothesis of valency, and attempts are made to give consistent representations of it, with the help of certain conventions, in constitutional or structural formulae (v. EQUIVALENCY; FORMULÆ; ISOMERISM).

M. M. P. M.

**CONTACT ACTION** v. CHEMICAL CHANGE.

**CONVALLAMARIN**  $C_{22}H_{34}O_{11}$ . Occurs, together with convallarin, in the lily of the valley (*Convallaria majalis*) from which plant it may be extracted by alcohol (Walz, *N. Jahrb. Pharm.* 1858, 10, 145; Langelbert, *J. Ph.* [5] 10, 26; *C. J.* 43, 271). Powder, with bitter taste, v. sol. water and alcohol, v. sl. sol. ether. Decomposed by boiling dilute  $H_2SO_4$  into glucose and convallamaretin, which separates in crystalline spangles, and becomes resinous in boiling water.

**Convallarin**. Rectangular columns. Insol. water and ether, v. sol. ether. Resolved by boiling dilute acids into glucose and convallarin.

**CONVICIN** v. VICIN.

**CONVOLVULIN**  $C_{15}H_{25}O_4$ . [150°]. Occurs in tuberose or officinal jalap root (from *Convolvulus Schiedanus*), and may be extracted from jalap resin by washing with ether, then exhausting with alcohol, and evaporating the alcoholic extract (Mayer, *A.* 95, 161; A. P. Stevenson, *Ph.* [3] 10, 644). A hard resin. Odourless, tasteless. Sol. chloroform, and hydrochloric acid; insol. water, ether, light petroleum,  $CS_2$ , benzene, and oil of turpentine. After being taken internally it is not secreted unaltered (Dragendorff, *C. C.* 1886, 589). Dissolves in  $H_2SO_4$  to a bright red colour. Potassium chromate, permanganate, nitrate, or chlorate give an odour of rancid butter and an olive green colour. Conc.  $HNO_3$  gives oxalic acid and ipomic acid  $C_{10}H_{16}O_4$ .

**Convulvolic acid**  $C_{15}H_{25}O_4$ . (?) [100°–120°]. Formed by boiling convolvulin with baryta-water (Kayser, *A.* 51, 81; Mayer, *A.* 83, 126; 95, 162). White hygroscopic substance; sol. water and alcohol, insol. ether.

**Salts.**— $KA' \frac{1}{2}aq$ : [100°–110°]; amorphous.— $BaA'_2$ — $PbA'_2$ .

**Convulvulinolic acid**  $C_{25}H_{39}O_{10}$ . [39°]. Formed, together with glucose, by the action of emulsin or of dilute acids on convulvolic acid. Minute needles: v. sl. sol. water, v. a. sol. alcohol, m. sol. ether. Taste bitter. Conc.  $H_2SO_4$  turns it red. Conc.  $HNO_3$  gives oxalic and ipomic acids. The same body, or an isomeric, is formed by fusing convolvulin or convulvolic acid with moist NaOH. It forms salts:  $BaA'_2aq$  (at  $100^\circ$ ).— $PbA'_2$ — $CuA'_2 \frac{1}{2}aq$  (at  $100^\circ$ ).

**CONYLENE** v. OCTINENE.

**CONYLENE BROMIDE** v. DI-BROMO-OCTYLENE.

**CONYLENE GLYCOL** v. DI-OXY-OCTYLENE.

**CONYRINE** is ( $\alpha$ )-PROPYL-PYRIDINE (q. v.).

**COPAIBA BALSAM**. Exudes from incisions in the stems of various species of *Copaifera*. Diuretic.

It contains a levorotatory terpene (Copaiba oil)  $C_{20}H_{32}$  (250°-260°); S.G. .9; V.D. 9.5. The terpene from ordinary copaiba balsam yields a crystalline hydrochloride  $C_{20}H_{32} \cdot 4HCl$  (77°), but those from Maracaibo balsam do not (Bonastre, *J. Ph.* 11, 529; Ader, *J. Ph.* 15, 95; Gerber, Brande's *Arch.* 30, 157; Blanchet, *A.* 7, 156; Soubeiran a. Capitaine, *J. Ph.* 26, 70; A. 34, 321; Posselt, *A.* 69, 67; Lowe, *Ph.* 14, 65; Strauss, *A.* 148, 151). The terpene from Maracaibo balsam yields terephthalic acid on oxidation (Brix, *M.* 2, 507). Moist copaiba oil distilled over sodium gives a dark blue hydrate  $C_{20}H_{32} \cdot 4aq$  (252°-260°). The different varieties of copaiba balsam also contain resins and resinous acids (Stoltze, *Jahrb. f. Pharm.* 27, 179; Oberdörfer, *Ar. Ph.* [2] 44, 172; Ulek, *Ar. Ph.* 122, 14; Stockhardt, *Ar. Ph.* 38, 12; Procter, *Ph.* 10, 603; Roussin, *J. Ph.* [4] 1, 321; Schweizer, *P.* 12, 784; 21, 172; Rose, *P.* 83, 83; Hess, *A.* 29, 140; Fehling, *A.* 40, 110; Wayne, *Am. Journ. Pharm.* [4] 3, 326; Siebold, *Ph.* [3] 8, 250; Bowman, *Ph.* [3] 8, 330; Martin a. Vigne, *J. Ph.* 1842, 52). On oxidation with  $K_2Cr_2O_7$  and  $H_2SO_4$ , copaiba balsam yields  $\alpha$ -di-methyl-succinic acid [140°] (Levy, *B.* 18, 8206).

**Copaivic acid**  $C_{22}H_{34}O_4$  (?) Extracted by alkalis from copaiba balsam (Rose, *A.* 13, 177; 40, 810; Flückiger, *J. pr.* 101, 235; Rush, *Ph.* [3] 10, 5). Crystalline.— $CaA'$ .— $PbA'$ .— $AgA'$ .

**Meta-copaivic acid**  $C_{22}H_{34}O_4$ . [206°]. Extracted by alkalis from Maracaibo balsam obtained from Columbia (Strauss, *A.* 148, 153). Plates. Insol. water, v. sol. alcohol and ether.— $CaA'$  aq. —  $Ag_2A'$  aq.

**Oxy-copaivic acid**  $C_{20}H_{32}O_4$ . [c. 120°]. Found in a balsam from Para (Fehling, *A.* 40, 110). Crystals. Forms an amorphous hydrate  $C_{20}H_{32}O_4 \cdot PbA'$ .— $AgA'$ .

**COPAL.** This name is given to a variety of resins which exude from different trees, e.g. *Rhus copallina*, *Eleocarpus copalifer*, *Hymenaea verrucosa*, *Damara australis*. They contain many resins, and often yield terpenes on distillation (Filhol, *A.* 44, 323; Thomson, *A.* 47, 351; Schibler, *A.* 113, 339; Unverdorben, *B. J.* 11, 265; Violette, *C. R.* 63, 461; Muir, *C. J.* 27, 733; Rennie, *C. J.* 39, 240). A similar substance (copalin) is found fossilised at Highgate (Johnston, *P. M.* [3] 14, 87).

**COPPELLIDINE** v. TRI-METHYL-PYRIDINE HEXAHYDRAIDE.

**COPPER GROUP OF ELEMENTS.** COPPER, SILVER, GOLD. These metals occur native; they have been known and used from very early times. They show a general resemblance to each other in their physical and chemical properties, but there are differences between them. The table in the next column presents some of their properties.

The three metals are hard, lustrous, malleable, tenacious, and ductile; they are good conductors of electricity; they crystallise in forms belonging to the regular system. Cu is oxidised by treating in air; Ag combines very slowly with O at extremely high temperatures; Au does not directly combine with O. Cu and Ag interact with acid to form salts; Au is acted on by *aqua regia*, but not by  $HClAq$  or  $HNO_3$  separately. Cu decomposes steam at a red heat; Ag and Au are without action on steam.

	Copper	Silver	Gold
Atomic weight	63.5	107.86	197
Molecular weights are unknown.

$[M \cdot S]$	20,270	5,540	
Heats of neutralisation of oxides (Thomsen).			
$[M \cdot O, 2HClAq]$	49,800	42,580	$[AuO^H, 3HClAq] = 18,440$

General formula and character of compounds.

—Oxides, MO and  $M_2O$ , also  $Au_2O_3$ . Sulphides, MS (except Ag),  $M_2S$ . Haloid compounds,  $MX_2$  (except Ag),  $MX$  or  $M_2X_2$ ,  $AuX_3$ . Salts,  $Cu_2X$ ,  $Ag_2X$ , and a few  $Au_2X$ ;  $CuX$ ; a few  $Au_3X$ ; ( $X = SO_4, 2NO_3, CO_3, 3PO_4, S_2O_8, \&c.$ ). The oxides  $Cu_2O$  and  $Au_2O_3$  are produced by reducing cupric and auric salts, e.g.  $CuSO_4$  aq and  $AuCl_3$  aq, in presence of an alkali;  $Ag_2O$  is obtained by adding alkali to an argentous salt, e.g.  $AgNO_3$  aq. Addition of alkali to a cupric salt, e.g.  $CuSO_4$  aq, ppts.  $CuO \cdot H_2O$ , which loses water on heating to dull redness; addition of alkali to an auric salt, e.g.  $AuCl_3$  aq, ppts.  $Au_2O_3 \cdot 3H_2O$ , which loses water at 100°, and at a higher temperature becomes  $AuO$ ; argentous oxide  $AgO$  is formed by the action of ozone on  $Ag_2O$ . Of the oxides of Cu,  $CuO$  is the more stable; it dissolves in acids and forms a large series of well-marked salts;  $Cu_2O$  forms a few salts by directly interacting with acids, but generally it reacts to form salts of  $CuO$  with separation of Cu. Of the oxides of Ag,  $Ag_2O$  is much the more stable; it reacts with acids to form argentous salts;  $AgO$  acts towards acids as a basic peroxide, forming argentous salts and evolving O. None of the oxides of Au is stable; a few salts corresponding to each are known, e.g.  $Au_2S_3O_8$  derived from  $Au_2O_3$ ,  $AuSO_4$  from  $AuO$ , and  $AuCl_3$  from  $Au_2O_3$ . The oxides of Cu and Ag are distinctly basic; moist  $Ag_2O$  acts like a weak alkali, although a hydroxide has not been certainly isolated.  $Au_2O_3$  and  $AuO$  are feebly basic;  $Au_2O_3$  is also feebly basic, but it likewise dissolves in  $KOHAq$  to produce a salt,  $KAuO_2$ , in which Au forms part of the negative radicle.

The sulphides  $Cu_2S$  and  $Au_2S$  are produced by the combined action of  $H_2S$  and reducing agents on cupric and auric salts; e.g. a cupric salt heated in  $H_2S$  and then in H gives  $Cu_2S$ ;  $AuCl_3$  dissolved in  $KCN$  aq and ppd. by  $H_2S$  gives  $Au_2S$ . Argentous salts give  $Ag_2S$  on addition of  $H_2S$ . The sulphides  $CuS$  and  $AuS$  are formed by reactions between  $H_2S$  and cupric or auric salts. Both sulphides of Cu, and sulphide of Ag, are stable;  $Cu_2S$  being the more stable of the Cu sulphides. These sulphides are basic, forming some compounds with the sulphides of less positive elements, e.g.  $Cu_2S \cdot Sb_2S_3$ ;  $Cu_2S$  also forms some double compounds in which it appears to be negative to the other constituent, e.g.  $K_2S_3Cu_2S_2CuS$ .  $Au_2S$  when freshly ppd. dissolves in water; both this sulphide and  $AuS$

dissolve in alkali sulphides to form sulpho-salts, e.g.  $\text{NaAuS}$ ,  $\text{KAuS}$ .

The salts of Cu belong to two series; e.g.  $\text{Cu}_2\text{Cl}_2$ , representative of cuprous salts, and  $\text{CuSO}_4$ , representative of cupric salts; the cupric salts are the more stable. Silver forms but one series of salts, the argentous salts, e.g.  $\text{AgNO}_3$ ,  $\text{Ag}_2\text{SO}_4$ . Few gold salts are known;  $\text{Au}_2\text{S}_3\text{O}_{10}$  is a representative of the aurous salts,  $\text{AuSO}_4$  represents the auro-auric salts, and  $\text{AuCl}_3$  belongs to the auric series. Auric chloride and bromide  $\text{AuCl}_3$  and  $\text{AuBr}_3$ , combining with  $\text{HCl}$  and  $\text{HBr}$  respectively, forming the monobasic acids  $\text{HAuCl}_4$  and  $\text{HAuBr}_4$ . Gold is distinctly the most negative of the three elements Cu, Ag, Au; the non-metallic character of Au is shown in the formation of aurates, e.g.  $\text{KAuO}_4$  derived from  $\text{Au}_2\text{O}_3$ , of sulpho-aurates, e.g.  $\text{NaAuS}$  and  $\text{KAuS}$ , derived from  $\text{AuS}$ , of the acids  $\text{HAuCl}_4$  and  $\text{HAuBr}_4$ , and in the instability of the salts of Au. Silver is distinctly metallic in all its chemical relations. Cu is also metallic, but the formation of such compounds as  $\text{K}_2\text{S}_2\text{Cu}_2\text{S}$ ,  $\text{S}_2\text{CuS}$  shows a tendency of Cu to react as a feebly non-metallic element.

The position of the elements Cu, Ag, Au in the scheme of classification based on the periodic law is peculiar (v. CLASSIFICATION, p. 204). These elements are placed in Group I; this group comprises Li, Na, K, Rb, and Cs, which are the most positive, and chemically the most metallic, of all the elements; but Cu finds a place in the *long period* containing the metals Fe, Ni, and Co; Ag comes in the *long period* which contains Rh, Ru, and Pd; and Au follows Os, Ir, and Pt. The three sections of Group VIII., viz. (1) Fe, Ni, Co, (2) Rh, Ru, Pd, (3) Os, Ir, Pt, appear to impress their own properties on the elements immediately preceding and succeeding them. Cu, Ag, and Au exhibit analogies at once with the other members of the group to which they belong, and with those metals of Group VIII. which form part of the *long periods* including Cu, Ag, and Au respectively. The analogies with the metals of Group VIII. are shown in the physical properties of Cu, Ag, and Au, and also to some extent in their general chemical characters. The analogies between the alkali metals and the elements of the Cu group are shown in the composition of the alkali salts and the cuprous salts, the argentous salts, and the few aurous salts which have been isolated; also in the basic character of cuprous, argentous, and aurous oxides. The existence of  $\text{AgO}$  and  $\text{Cu}_2\text{O}$ , and the fact that these behave as peroxides, establishes an analogy between Cu and Ag on one side, and Na or K on the other; Ag also forms an alum,  $\text{Ag}_2\text{SO}_4 \cdot \text{Al}(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$ ; moist  $\text{Ag}_2\text{O}$  reacts as a weak alkali; the non-existence of any salts of Ag except those of the type  $\text{AgX}$

( $\text{X} = \frac{\text{SO}_4}{2}\text{NO}_3$ , &c.) establishes another resemblance between Ag and the alkali metals. It

should be noted here that the molecular formula of cuprous chloride is  $\text{Cu}_2\text{Cl}_2$ , while that of silver chloride is  $\text{AgCl}$ ; in this point Ag resembles the alkali metals, as the molecular formulæ  $\text{KCl}$  and  $\text{CsCl}$  have been established. Au differs more than either Cu or Ag from the alkali metals; this difference is emphasised in the acidic characters of  $\text{Au}_2\text{O}_3$ ,  $\text{Au}_2\text{S}_3$ , and  $\text{AuS}$ , in the formation of

$\text{HAuCl}_4$ , &c., and in the great instability of the salts of Au; on the other hand, the solubility in water of  $\text{Au}_2\text{O}$  and  $\text{Au}_2\text{S}$  suggests the solubility in water of the oxides and sulphides of the alkali metals. The methods of formation of  $\text{Au}_2\text{O}$  and  $\text{Au}_2\text{S}$  suggest the processes by which  $\text{Cu}_2\text{O}$  and  $\text{Cu}_2\text{S}$  are formed. (For more details about the metals of the copper group, v. COPPER, SILVER, GOLD; v. also NOBLE METALS.) M. M. P. M.

**COPPER.** Cu. At. w. 63.2. Mol. w. unknown (c. 1100°; for various determinations v. Carnelley's *Melting and Boiling Points*). S.G. varies from 8.36 for finely divided Cu to 8.95 for hammered Cu (v. Playfair a. Joule, *C. S. Mem.* 3, 57; Dick, *P. M.* [4] 11, 409; Baudrimont, *J. pr.* 7, 287; Hampe, *C. C.* 6, 379; Marchand a. Scheerer, *J. pr.* 27, 193, &c.). S.H. ( $15^\circ$ - $100^\circ$ ) .0933; ( $16^\circ$ - $172^\circ$ ) .0948; ( $17^\circ$ - $247^\circ$ ) .0968 (Bade, *Mém. B.* 27 [1855-56]). C.E. (linear  $0^\circ$ - $100^\circ$ ) .0001666 (Matthiessen, *Fr.* 15, 220). C.E. (cubical)  $V = V_0 (1 + .00004443t + .0000000555t^2)$  (Matthiessen, *L.c.*). T.C. ( $\text{Ag} = 100$ ) 73.6 (Wiedemann a. Franz, *P. M.* [4] 7, 33). E.C. at c.  $19^\circ$  (Ag wire = 100), 93 (Matthiessen, *Tr.* 1860; *Pr.* 11, 126). E.C. at  $0^\circ$  (Hg at  $0^\circ = 100$ ) c. 52.54 (Siemens, *P. M.* [4] 21, 24). E.C. is much decreased by small quantities of P, As, Zn, Fe, Sn, &c. (v. Matthiessen, *L.c.*). Emission-spectrum characterised by lines in the green 5217, 5153, and 5105 (Thalen) Hartley (*Tr.* 1884, 105) gives the following as prominent lines of high refrangibility: 3273.2, 3246.9, 2544.6, 2370.1, 2248.2, 2247.7, 2244, 2243.5. Crystallises in regular octahedra. S.V.S. c. 7.1.

**Occurrence.**—Very abundantly; as metal, oxide, sulphide, chloride, arsenate, carbonate, phosphate, sulphate, silicate, and vanadate. Small quantities of salts of Cu are found in seaweed (Malaguti, *A. Ch.* [3] 28, 129); in sea-water (Dieulaufait, *A. Ch.* [5], 18, 349); in the blood of various animals (v. Harles, *Chem. Gazette*, 1848, 214; Genth, *P.* 95, 60; *J.* 1848, 871, 874; 1849, 530; Ulex, *J. pr.* 94, 376; Wicke, *W. J.* 1866, 73); in flour, eggs, &c. (Odling a. Dupré, *Gay's Hospital Reports*, October 1858); in all plants that live on primary rocks or on soil derived from these rocks (Dieulaufait, *A. Ch.* [5] 19, 550). In many mineral waters. Copper has been known and used for making tools from very early times.

**Formation.**—1. From native oxides and carbonates by melting with silica in presence of lime and charcoal; silicate of calcium is formed and the charcoal reduces the oxide of copper.—2. From native sulphides, and sulphides of Cu with Fe, &c., by roasting and then melting;  $\text{CuO}$  is first formed, and then reacts with  $\text{FeS}$  in the ores to form  $\text{CuS}$  and  $\text{Fe}_2\text{O}_3$ , the greater part of the iron passes into the slag; by repeating this process approximately pure  $\text{CuS}$  is obtained; this is roasted so as to convert a part of it into  $\text{CuO}$ , the mixture of  $\text{CuO}$  and  $\text{CuS}$  is melted in closed apparatus when  $\text{SO}_2$  and Cu are produced ( $2\text{CuO} + \text{CuS} = 3\text{Cu} + \text{SO}_2$ ); the impure copper is refined by *poling*, a process consisting in stirring the melted metal, covered with a layer of anthracite, with a green pole of birch or oak, the heated wood evolves reducing gases ( $\text{CO}$ ,  $\text{H}_2\text{O}$ , hydrocarbons).—3. From oxide, or from roasted native sulphides, by treatment with heated conc.  $\text{NaClAq}$  whereby  $\text{CuCl}_2$  is formed and dissolved, followed by pptn. by means of scrap iron.—4. From oxide,

or from native sulphides, by treatment with hot  $\text{NaClAq}$  and  $\text{FeSO}_4\text{Aq}$  mixed with  $\text{CaCl}_2$ , and subsequent ppn. by scrap iron; the chief reaction is  $\text{CuO} + 2\text{FeCl}_2\text{Aq} = \text{Fe}_2\text{O}_3 + \text{Cu}_2\text{Cl}_2\text{Aq} + \text{CuCl}_2\text{Aq}$ .  
**J. By electrolysis of solution of Cu salts.**

**Preparation.**—1. Commercial copper is dissolved in fairly conc.  $\text{H}_2\text{SO}_4\text{Aq}$ ;  $\text{PbSO}_4$  is pptd. by diluting largely with water; the liquid is filtered and poured on to Zn or Fe (sifted Zn powder is best), and digested until nearly but not quite colourless; the pp. is freed from Zn or Fe by treatment with warm dilute  $\text{HClAq}$ ; it is then washed, dried, and fused under borax; or the pp. of Cu after digestion with acid is washed, dried quickly at  $75^\circ$ , and heated in a stream of H (*Böttger, A. 89, 172*). [For impurities in commercial copper v. *Abel a. Field, C. J. 14, 280*.]—2.  $\text{CuSO}_4\text{Aq}$  is mixed with  $\text{K}_2\text{C}_2\text{O}_4\text{Aq}$ , and  $\text{H}_3\text{PO}_4\text{Aq}$  is added; Cu ppts. quickly (*Wöhler, A. 79, 128*).—3. Commercial copper is dissolved in equal parts of  $\text{H}_2\text{SO}_4$  and water; the solution is boiled with a little  $\text{HNO}_3$  (to oxidise Fe salts) and crystallised, the crystals are recrystallised from water, dissolved and electrolysed (*Millon a. Commaille, C. R. 56, 1249*).—4. *Hampe (Fr. 1874, 352)* adds  $\text{KOH}$  to  $\text{CuSO}_4\text{Aq}$  until a pp. of basic salt is formed (this pp. contains any Bi which might have been present in the  $\text{CuSO}_4$ ); the filtered solution is evaporated and crystallised; the crystals are dissolved in the smallest possible quantity of water; 20 cc. conc.  $\text{HNO}_3\text{Aq}$  are added to every 500 cc. solution; an electric current is passed through this liquid using cone-shaped Pt electrodes, the current being stopped before the whole of the Cu is pptd., whereby Fe, Zn, and other metals remain in solution; the pptd. Cu is washed and dissolved in pure  $\text{HNO}_3\text{Aq}$ , the solution is evaporated to dryness, and the  $\text{Cu(NO}_3)_2$  obtained is decomposed by heating; the Cu is reduced by heating in pure H. The Cu thus obtained is dissolved in  $\text{H}_2\text{SO}_4\text{Aq}$ ; crystals of  $\text{CuSO}_4$  are obtained, and the foregoing process of electrolysis is repeated. The metal obtained by the second electrolysis is boiled in water, to remove traces of undecomposed  $\text{CuSO}_4$ . The Cu thus obtained is heated to a very high temperature in a porcelain tube in a current of pure  $\text{CO}_2$  (about 60 grams Cu at a time) until melted. H is then passed over the molten metal for a time, and finally it is allowed to cool in  $\text{CO}_2$ .—5. Finely divided Cu may be obtained (a) by reducing CuO in a stream of H; (b) by strongly heating a mixture of 5 parts  $\text{Cu}_2\text{Cl}_2$  with 6 parts dry  $\text{Na}_2\text{CO}_3$ , and some  $\text{NH}_4\text{Cl}$ , and washing the product (*Liebig a. Wöhler, P. 21, 582*); (c) by digesting  $\text{CuSO}_4\text{Aq}$  with sifted zinc powder, pouring off the liquid before quite colourless, washing the residue with dilute  $\text{HClAq}$ , pressing between paper, and drying at about  $75^\circ$ .

**Properties.**—A reddish-yellow solid. The red colour of ordinary Cu is due to a film of  $\text{Cu}_2\text{O}$ . Crystallises from molten state, or by slow electrolytic deposition, or by ppn. by means of P, in cubes and octahedra belonging to the regular system. Melts at high temperature, about  $1100^\circ$ ; expands on solidifying; very ductile, malleable, hard, and elastic; fairly tenacious; very good conductor of heat and electricity; may be highly polished; sonorous. Copper melted in air assumes a vesicular structure on cooling owing to escape of bubbles of gas, either CO formed when

the Cu is melted under charcoal, or  $\text{SO}_2$  formed by action of traces of S in the Cu on traces of CuO present (*Dick, P. M. [4] 11, 409*; *Matthiessen a. Russell, P. M. [4] 23, 81*). Finely divided Cu may readily be hammered and pressed into masses. Cu is slightly volatile when very strongly heated (*Riemsdyk, C. N. 20, 32*); in the O-H flame it boils and partially volatilises; *Despretz (C. R. 48, 382)* volatilised Cu in a H stream by passing a current through it from 600 Bunsen-cells. Molten Cu absorbs various gases (*Hampe, Zeitschr. f. d. preuss. Berg-Hütten und Salinen Wesen, 1874 a. 1875*; *Graham, P. M. [4] 32, 503*; *Lucas, A. Ch. 12, 402*; *Marchand a. Scheerer, J. pr. 27, 195*; *Dick, P. M. [4] 11, 409*; *Matthiessen a. Russell, P. M. [4] 23, 81*; *Lenz, J. pr. 108, 438*). H is absorbed in considerable quantity (finely divided Cu absorbs 6 vols. of H, *Graham*); the whole of the H is not given out on cooling, or on heating to  $160^\circ$  (*Lietzenmayer, B. 11, 306*); but if the Cu is heated to  $250^\circ$  it is slightly oxidised, and if it is then heated to redness in a nearly closed tube a little  $\text{H}_2\text{O}$  is formed, and the CuO is reduced (*L. l.c.*). Cu prepared by reducing CuO in H retains a little H, which may be removed by the method described; or by heating in a stream of formic acid vapour (*Wegli, B. 15, 1139*).  $\text{SO}_2$  and CO are also absorbed by molten Cu; CO, and N are not absorbed. Cu in masses is unchanged in dry air; when gently heated it is superficially oxidised to  $\text{Cu}_2\text{O}$ , at a higher temperature  $\text{Cu}_2\text{O}$  and CuO are formed; finely divided Cu burns to CuO in air considerably under a red heat. In moist air containing  $\text{CO}_2$ , Cu becomes covered with a film of greenish basic carbonate; after a considerable time the interior of such Cu contains crystals of  $\text{Cu}_2\text{O}$  (*D. P. J. 206, 200*). Finely divided Cu, obtained by reducing CuO under red heat, is changed by ordinary air to  $\text{Cu}_2\text{O}$ . Cu in mass decomposes  $\text{H}_2\text{O}$  at a full red heat, and then only slowly. Cu is slowly acted on by many dilute organic acids in the air; etables should not, therefore, be allowed to remain in Cu vessels exposed to air, although they may be boiled with water in such vessels, as then the escaping steam removes the air. Cu is slightly dissolved by  $\text{HClAq}$  or  $\text{H}_2\text{SO}_4\text{Aq}$  in presence of air; conc. hot  $\text{H}_2\text{SO}_4$  forms  $\text{CuSO}_4$ , and CuS with evolution of  $\text{SO}_2$ ; conc. hot  $\text{HClAq}$  forms  $\text{Cu}_2\text{Cl}_2$  and H;  $\text{HNO}_3\text{Aq}$  readily dissolves the metal with evolution of N oxides;  $\text{SO}_4\text{Aq}$  slowly forms  $\text{CuSO}_4$  and  $\text{H}_2\text{SO}_4\text{Aq}$ .  $\text{NH}_4\text{Aq}$  in presence of O, acts on Cu, forming  $\text{Cu-NH}_3$ , nitrate; heated in  $\text{NH}_3$ , Cu nitride is formed.  $\text{NH}_3$ , salts, and some other metallic salts, in solution dissolve appreciable quantities of Cu. Cu combines directly with Cl, Br, S, P, Si, As, Sb, and many metals (v. COPPER, ALLOYS OF).

The atomic weight of Cu has been determined (1) by reducing CuO in H (*Berzelius, P. 8, 182*; *Erdmann a. Marchand, J. pr. 81, 391*; *Millon a. Commaille, C. R. 57, 147*; *Hampe, Fr. 13, 351*); (2) by electrolysing  $\text{CuSO}_4\text{Aq}$  and weighing the Cu (*Hampe, Fr. 18, 867*; *Shaw, P. M. [5] 23, 138*); (3) by reducing  $\text{AgNO}_3\text{Aq}$  by pure Cu and weighing the Ag (*Richards, P. Am. A. 22, 23, 177*). The number 63.2 is confirmed by the S.H. of Cu, and by comparison of the crystalline forms of Cu compounds with some ferrous compounds, and also with compounds of Co and Ni, and with some compounds of Ag.

Copper is distinctly a metallic element; its forms salts by replacing the H of most acids; most of these salts belong to the series  $\text{CuX}_2$ , where  $\text{X} = \text{Cl}, \text{NO}_3, \frac{\text{SO}_4}{2}, \text{etc.}$ ; but several cuprous

salts,  $\text{Cu}_2\text{X}_2$ , are also known. There are indications of the existence of compounds of Cu with strongly positive metals and O, in which the Cu forms part of the negative radicle of the salts, but such salts have not been isolated (v. Corren, oxides of). Copper is analogous in its chemical relations on one hand to Ag, and on the other to Fe, Ni, and Co; it also shows similarities with Au and with the alkali metals. In the periodic classification of the elements Cu is generally placed both in Group VIII., which comprises Fe, Ni, Co, and the Pt metals, and also in Group I., which includes H, the alkali metals, Ag, and Au (v. COPPER GROUP OF ELEMENTS). The valency of the atom of Cu has not been determined with certainty; the only compound whose molecular weight in the gaseous state has been determined is  $\text{Cu}_2\text{Cl}_2$ , the atom of Cu is most probably divalent in this molecule.

**Allotropic form of copper.** Schützenberger (C. R. 86, 1265) described a bronze-coloured solid, obtained by electrolysis a solution of Cuacetate containing some basic acetate (produced by boiling); the negative electrode consisted of a plate of Pt, and the positive of a somewhat larger Cu plate; 2 Bunsen- or 3 Daniell-cells were used; the electrodes were placed 3 or 4 centims. apart. The bronze-coloured body was deposited on the face of the Pt electrode turned towards the Cu plate. The deposit was lustrous; very brittle; S.G. c. 8 to 8.2; it contained 5 to 10 p.c. CuO; it was oxidised readily in moist air; cold  $\text{HNO}_3\text{Aq}$  (10 p.c.) dissolved it readily with evolution of nearly pure  $\text{N}_2\text{O}$ . This substance was changed to ordinary Cu by heat. No H was evolved by heating to  $100^\circ$  in  $\text{CO}_2$ . Wiedemann (W. 6, 81) says that the substance obtained by electrolysis Cu acetate as described is ordinary Cu containing CuO sometimes amounting to 35 p.c.; Schützenberger (Bl. [2] 31, 291) asserts that his allotropic copper is changed to ordinary copper without change of mass (v. also Mackintosh, C. N. 44, 279).

**Reactions.**—1. Cu decomposes water slowly at a full red heat (Regnault, A. Ch. 62, 364).—2. In dry air Cu is unchanged; but in ordinary moist air it becomes covered with a film of a basic carbonate (D. P. J. 206, 200), and crystals of  $\text{Cu}_2\text{O}$  are formed in the interior of the mass.—3. Heated in oxygen CuO is formed; very finely divided Cu is said to form  $\text{Cu}_2\text{O}$  in oxygen without heating.—4. Not acted on by weak acids in absence of air, but slowly dissolved by dilute  $\text{HClAq}$ , &c., in presence of air. [Thomsen gives these thermal data (Th. 3, 320):— $[\text{Cu}, \text{O}^*, \text{SO}^*] = 111,490$ ;  $[\text{Cu}, \text{O}^*, 2\text{NO}^*, 6\text{H}^*\text{O}] = 96,950$ ;  $[\text{Cu}, \text{O}, \text{H}^*\text{SO}^*\text{Aq}] = 55,960$ ;  $[\text{Cu}, \text{O}, 2\text{HNO}^*\text{Aq}] = 52,410$ .—5. In very conc. nitric acid Cu is passive, because of formation of layer either of NO or CuO (cf. Passivity of Iron, under Iron). Dissolves rapidly in less conc. nitric acid giving off NO and  $\text{N}_2\text{O}$ .—6. Conc. hydrochloric acid in presence of air dissolves finely divided Cu, forming  $\text{Cu}_2\text{Cl}_2$  and evolving H (Odling, C. J. 9, 291); less conc.  $\text{HClAq}$  slowly dissolves Cu when

heated with it in presence of air.—7. Dilute sulphuric acid in presence of oxygen slowly dissolves Cu (forming  $\text{H}_2\text{O}$ , according to Traube, B. 18, 1887). Conc.  $\text{H}_2\text{SO}_4$  acts on Cu even at  $20^\circ$ , forming  $\text{Cu}_2\text{S}_3$  and  $\text{CuSO}_4$ ; at higher temperatures  $\text{SO}_2$  is evolved, until at  $270^\circ$  the action is represented by the equation  $\text{Cu} + 2\text{H}_2\text{SO}_4 = \text{CuSO}_4 + \text{SO}_2 + 2\text{H}_2\text{O}$  (Pickering, C. J. [2] 18, 112).—8. Sulphurous acid slowly acts, forming sulphite and  $\text{H}_2\text{SO}_4\text{Aq}$ ; if large excess of  $\text{H}_2\text{SO}_4\text{Aq}$  is used,  $\text{CuS}$  is formed along with S (Causse, Bl. [2] 45, 8).—9. Conc. hydriodic acid attacks Cu forming  $\text{Cu}_2\text{I}_2$  and H.—10. Aqueous solutions of many metallic salts slowly dissolve Cu; chlorides and nitrates, especially of ammonium, are the most active (v. Pattison Muir, C. N. 34, 223, 234; Carnelley, C. J. [2] 15, 1). According to Traube (B. 18, 1887) Cu dissolves in  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$  with production of  $\text{H}_2\text{O}_2\text{Aq}$ .—11. Ammonia solution slowly dissolves Cu with previous formation of CuO; Schönbein (B. B. 1856, 580) says that  $\text{Cu-NH}_3$  nitride is produced. Heated in ammonia to full redness, Cu becomes brittle and now contains N, a nitride is probably formed (Warren, C. N. 55, 155).—12. Sulphuretted hydrogen forms  $\text{CuS}$ .—13. Many fatty oils, e.g. olive, rape, linseed, &c., dissolve considerable quantities of Cu (Thomson, C. N. 34, 176, 200, 213).

**Combinations.**—Copper combines directly with the following non-metallic elements either at the ordinary or higher temperatures: chlorine, bromine, iodine, oxygen, sulphur, selenium, phosphorus, silicon, arsenic, antimony (for details v. COPPER, CHLORIDE OF; BROMIDE OF, &c.). It is not quite certain whether Cu combines directly with nitrogen or not; Blondlot (C. R. 102, 210) got indications of combination when discs of Cu and Pt were strongly heated in an atmosphere of N (cf. COPPER, NITRIDE OF).

**Detection and Estimation.**—Cu salts in solution give a deep-blue colour with excess of  $\text{NH}_3\text{Aq}$ ; a mahogany-coloured pp. of ferrocyanide of Cu in very dilute liquids. Minute traces of Cu may be detected by immersing a small couple of Zn and Pt wires in the liquid, and then exposing the Pt wire to the vapour given off by adding conc.  $\text{H}_2\text{SO}_4$  to KBr; if a trace of Cu has been deposited on the Pt a deep-violet colour is produced, due to formation of a compound of  $\text{CuBr}_2 \cdot x\text{H}_2\text{O}$  with HBr (Cresti, G. 7, 220). Copper is often estimated by ppn. with  $\text{KOH Aq}$ , heating, and weighing as CuO; also by ppn. as metal by means of Zn and Pt. Volumetric methods of estimation are based on the reaction of ammoniacal Cu solutions with  $\text{KCN Aq}$  to form colourless  $\text{Cu}(\text{CN})_2 \cdot 2\text{NH}_4\text{CN}$ ; on the reaction of Cu solutions with  $\text{KI Aq}$  to form  $\text{Cu}_2\text{I}_2$  and I; on the reaction of  $\text{Cu}_2\text{O}$  with  $\text{Fe}_2\text{Cl}_2\text{Aq}$  to form  $\text{CuCl Aq}$  and  $\text{FeCl}_2\text{Aq}$ ; and on other reactions. Cu may also be estimated by electrolysis (v. Glassen, Quantitative Analysis durch Electrolyse (Berlin, 1886)). For details of methods a Manual of Analysis must be consulted.

**Copper, Alloys of.**—Many alloys of Cu are much used in manufactures because of their malleability, hardness, and durability, and in some cases sonorosity. Only a brief account of the chief classes of these alloys is given here; for details of those alloys which are of especial

technical importance reference must be made to the *Dictionary of Technical Chemistry*.

1. With *aluminium*. Aluminas and CuO are strongly heated with carbon in about the ratio Al:9CuO:9C. The alloy which results has the composition Cu<sub>2</sub>Al; it has the colour of gold, is very tenacious and malleable, very hard, and takes a high polish. This alloy, or an alloy containing from 5 to 10 p.c. Al, is generally known as *aluminium-bronze* (v. Debray, *C. R.* 43, 925).

2. With *antimony*. Cu and Sb alloy in almost all proportions. Compounds SbCu<sub>2</sub> and SbCu, probably exist (v. Ball, *C. J.* 53, 167). These alloys are brittle. Sb is present in many varieties of bronzes and in alloys for making parts of locomotives. For action of acids on alloys of Sb and Cu v. Calvert a. Johnson, *T.* 1858, 849.

3. With *arsenic*; v. COPPER, ARSENIDES OF.

4. With *bismuth*; various alloys are formed by heating the metals together; an alloy of 2 parts Bi with 1 part Cu expands after solidification (Marx, *S.* 58, 470).

5. With *gold* v. Roberts, *A. Ch.* [5] 13, 133.

6. With *iron*. Cu is alloyed with iron by fusion. (For description of alloys v. Mushet, *P. M.* (3) 6, 81.)

7. With *lead*. Cu and Pb melted together at a red heat form alloys; but the fused mass tends to separate into two layers; the upper containing much Cu and little Pb, and the lower much Pb and little Cu; separation is partly prevented by rapid cooling. Pb is found in many clock-metals and bronzes.

8. With *nickel*. Alloys of Cu and Ni, with about 10Cu and 4Ni, are nearly white; alloys containing Cu, Ni, and Zn are largely used under the names of *German silver*, *Packfong*, &c.

9. With *silver*. Cu and Ag alloy in very varied proportions (for details v. Roberts, *A. Ch.* (5) 13, 111).

10. With *tin*. The various bronzes, gun-metals, and bell-metals, are alloys of Cu and Sn; these alloys are formed by fusing the two metals together. Many bronzes contain Pb, and some contain small quantities of Fe and Sb. For details of the manufacture and properties of the copper-tin alloys v. *Dictionary of Technical Chemistry*. Two compounds of Cu and Sn appear to exist, Cu<sub>2</sub>Sn and Cu<sub>3</sub>Sn; the evidence is based on the variations in the specific gravities, electrical conductivities, and other physical properties, of the alloys of Cu and Sn (v. Matthiessen, *T.* 1860, 161; Riche, *C. R.* 55, 1862; Lodge, *P. M.* (5) 8, 554; Calvert a. Johnson, *T.* 1858, 849; Roberts, *P. M.* (5) 8, 58, 551; Laurie, *C. J.* 53, 104; Ball, *C. J.* 53, 167).

11. With *zinc*. Ordinary brass is an alloy of about 2 parts Cu to 1 part Zn; many alloys of the two metals in various proportions are used in manufactures under the names of *Pinchbeck*, *Mosaic gold*, &c. Modern bronze is generally an alloy of Cu with *sinc* and *tin*. These alloys are formed either by fusing the metals together, or by heating Cu with ZnO and charcoal. In some cases one metal is added to the other from solution. For details regarding the manufacture, properties, and uses of the various bronzes, &c., v. *Dictionary of Technical Chemistry*. There are indications of the formation of a com-

pound of Cu and Zn, viz. CuZn, (v. Laurie, *C. J.* 53, 104). For action of acids on Cu-Zn alloys v. Calvert a. Johnson, *C. J.* [2] 4, 435; also Matthiessen, *C. J.* [2] 4, 502.

Copper, Antimonate of. Cu(SbO<sub>3</sub>)<sub>2</sub>·5H<sub>2</sub>O (Fremy, *A. Ch.* [3] 12, 499; Heffter, *P.* 86, 418).

Copper, Antimonides of (v. COPPER, ALLOYS OF).

Copper, Arsenates of. Cu<sub>2</sub>H<sub>2</sub>(AsO<sub>4</sub>)<sub>2</sub>·2H<sub>2</sub>O, and Cu<sub>3</sub>(AsO<sub>4</sub>)<sub>2</sub> (v. ARSENIC, ACIDS OF, vol. i. 308).

Copper, Arsenides of. The compounds Cu<sub>2</sub>As, Cu<sub>3</sub>As, and Cu<sub>4</sub>As, occur native as *Domeykite*, *Algodonite*, and *Darwinite*, respectively. According to Lippert (*J. pr.* 81, 168) the grey deposit obtained by heating Cu in an HCl solution of As<sub>2</sub>O<sub>3</sub> in Cu<sub>2</sub>As; when this is heated in H<sub>2</sub>, Cu<sub>2</sub>As remains.

Copper, Arsenites of. CuHASO<sub>3</sub>, and Cu(AsO<sub>2</sub>)<sub>2</sub>; v. ARSENIC, ACIDS OF, vol. i. 806.

Copper, Boride of. When amorphous B is heated with Cu in a crucible for some hours, above the M.P. of Cu, a yellow, very hard, brittle, mass is obtained, S.G. 8.116; this is Cu<sub>2</sub>B<sub>2</sub> according to Marsden (*C. J.* 37, 672).

Copper, Borofluoride of. Cu(BF<sub>4</sub>)<sub>2</sub>, v. under COPPER, FLUORIDES OF.

Copper, Bromides of. Two bromides are known, CuBr<sub>2</sub>, and Cu<sub>2</sub>Br<sub>2</sub> (or CuBr). The molecular weight of neither in the gaseous state has been determined; but judging from the chlorides the formulæ given are probably molecular. Thomsen gives the thermal values [Cu<sup>+</sup>, Br<sup>-</sup>] = 49,970; [Cu, Br<sup>-</sup>] = 32,580; [Cu<sup>+</sup>Br<sup>-</sup>, Br<sup>-</sup>] = 15,190; [Cu, Br<sup>-</sup>, Aq] = 40,830 (*Th.* 3, 319).

I. COPRIC BROMIDE, CuBr<sub>2</sub> (*Copper dibromide*). Prepared by dissolving Cu(OH)<sub>2</sub> in HBrAq, or digesting Cu turnings with excess of BrAq, or adding KBrAq to CuSiF<sub>6</sub>Aq; the green solution turns brown on evaporation; when the residue is gently heated, CuBr<sub>2</sub> remains as a graphite-coloured fusible mass. If the green solution is evaporated *in vacuo* over H<sub>2</sub>SO<sub>4</sub>, CuBr<sub>2</sub> is obtained in lustrous iodine-coloured crystals (Rammelsberg, *P.* 55, 246). By evaporating in air, Berthelot (*A. Ch.* 44, 385; v. also Löwig, *P.* 14, 485) obtained greenish-brown crystals of CuBr<sub>2</sub>·5H<sub>2</sub>O. CuBr<sub>2</sub> is deliquescent and very soluble in water; when heated it gives CuBr and Br. This bromide combines with ammonia to form CuBr<sub>2</sub>·5NH<sub>3</sub> and CuBr<sub>2</sub>·3NH<sub>3</sub>; the former is a blue powder obtained by passing NH<sub>3</sub> over CuBr<sub>2</sub>; the latter forms dark-green crystals, obtained by adding alcohol to CuBr<sub>2</sub>Aq saturated with NH<sub>3</sub> (Rammelsberg, *P.* 55, 246). These double compounds dissolve in water; on dilution Cu(OH)<sub>2</sub> is added; when heated they give off NH<sub>3</sub> and NH<sub>4</sub>Br and leave a mixture of CuBr<sub>2</sub> and CuO.

II. COPROUS BROMIDE. Cu<sub>2</sub>Br<sub>2</sub> (*Copper monobromide*). Prepared by heating CuBr<sub>2</sub>, by passing Br over heated Cu, or by reaction between Cu and CuBr<sub>2</sub>Aq mixed with FeBr<sub>2</sub>Aq (Renault, *C. R.* 59, 819). A white powder, insoluble in water. S.G. 4.72; M.P. = 504°; B.P. between 861° and 964° (Cartelley a. Williams, *C. J.* 37, 125). Not decomposed by conc. H<sub>2</sub>SO<sub>4</sub>, but by HNO<sub>3</sub>Aq (Berthelot, *A. Ch.* [2] 44, 386; Löwig, *P.* 14, 485). Turns bluish in sunlight and is then less soluble than before in NaClAq or Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>Aq (Renault, *C. R.* 59, 819).

**Copper, Chlorides of.** Two chlorides of copper are known,  $\text{CuCl}_2$  and  $\text{CuCl}$  or  $\text{Cu}_2\text{Cl}_2$ . Many experiments have been made on the V.D. of cuprous chloride; it is very probable that the molecular formula of this salt is  $\text{Cu}_2\text{Cl}_2$ . Thomsen gives the thermal data [ $\text{Cu}^2, \text{Cl}^2$ ] = 65,750; [ $\text{Cu}, \text{Cl}^2, 2\text{H}^2\text{O}$ ] = 58,500; [ $\text{CuCl}^2, 2\text{H}^2\text{O}$ ] = 6,870; [ $\text{Cu}, \text{Cl}^2, \text{Aq}$ ] = 62,710 (Th. 8, 819).

**I. COPROUS CHLORIDE.**  $\text{CuCl}_2$ . (*Copper dichloride*.)

**Preparation.**—1. By burning Cu in Cl gas, or by passing Cl over heated  $\text{CuCl}$ .—2. By dissolving Cu in *aqua regia*, or in boiling conc.  $\text{HClAq}$  in presence of air, or by dissolving  $\text{CuO}$  or  $\text{CuCO}_3$  in hot  $\text{HClAq}$ ; the green solutions thus obtained are evaporated and the crystals of  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$  which form are heated to  $100^\circ$ .—3. By mixing  $\text{NaClAq}$  with  $\text{CuSO}_4\text{Aq}$ , evaporating, filtering from  $\text{Na}_2\text{SO}_4$ , evaporating, and heating the  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$  obtained.

**Properties and Reactions.**—A brownish-yellow, deliquescent, solid; melts at red heat and gives  $\text{CuCl}$  and  $\text{Cl}$ . Easily soluble in water, solution in a very little water is dark-green (Solly, P. M., 1848, 367); on addition of more water it becomes green, colour of very dilute solutions is greyish-blue (Gladstone, C. J. 8, 211, says that  $\text{CuCl}_2 \cdot 2\text{CuO} \cdot 4\text{H}_2\text{O}$  is formed); addition of conc.  $\text{HClAq}$  or better  $\text{H}_2\text{SO}_4$ , produces a yellow colour in a green solution of  $\text{CuCl}_2$ . Franz (J. pr. [2] 5, 274) gives the following data showing the composition and S.G. of  $\text{CuCl}_2\text{Aq}$ :

P.c. $\text{CuCl}_2$	S.G.	P.c. $\text{CuCl}_2$	S.G.
5	1.0455	25	1.2918
10	1.092	30	1.3618
15	1.1565	35	1.4417
20	1.2223	40	1.5284

$\text{CuCl}_2$  is soluble in alcohol and ether; alcoholic solutions burn with green flame.  $\text{CuCl}_2\text{Aq}$  ppd. by  $\text{KOH}$  yields various oxychlorides (v. COPPER, OXYHALOID COMPOUNDS or). For reactions of  $\text{CuCl}_2$  with metallic sulphides, v. Rammelsberg (C. J. 30, 374), and Raschig (A. 238, 1).

**Combinations.**—1. With water to form  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ ; obtained by evaporating solutions of  $\text{CuCl}_2$  and crystallising (v. *supra*); rhombic prisms  $a:b:c = 9179:1:4627$  (Gm.-K. [6th ed.] 3, 642); lose  $2\text{H}_2\text{O}$  at  $100^\circ$ , or over  $\text{H}_2\text{SO}_4$  (cf. Vogel, D. P. J. 136, 239, with Graham, A. 29, 31).—2. With ammonia to form  $\text{M} \cdot 2\text{NH}_3$ ,  $\text{M} \cdot 4\text{NH}_3 \cdot \text{H}_2\text{O}$ , and  $\text{M} \cdot 6\text{NH}_3$  [ $\text{M} = \text{CuCl}_2$ ] (Kane, A. Ch. 72, 273; Rose, P. 20, 155).  $\text{CuCl}_2 \cdot 6\text{NH}_3$  is formed by passing  $\text{NH}_3$  over  $\text{CuCl}$  as long as absorption continues; when heated to  $149^\circ$ ,  $\text{NH}_3$  is evolved and  $\text{CuCl}_2 \cdot 2\text{NH}_3$  remains. When  $\text{NH}_3$  is passed into hot conc.  $\text{CuCl}_2\text{Aq}$  until the pp. which forms has re-dissolved, and the liquid is allowed to cool,  $\text{CuCl}_2 \cdot 4\text{NH}_3 \cdot \text{H}_2\text{O}$  separates in dark-green octahedra which lose  $\text{NH}_3$  on drying.—3. With ammonia and salammiac to form  $\text{CuCl}_2 \cdot 2\text{NH}_3 \cdot 2\text{NH}_4\text{Cl}$ ; obtained by boiling Cu turnings with conc.  $\text{NH}_4\text{ClAq}$  till a deep-blue liquid is obtained, filtering from  $\text{Cu}_2\text{Cl}_2 \cdot 2\text{NH}_3$ , which separates, allowing the filtrate to oxidise in the air until it becomes greenish, and cooling (Ritthausen, J. pr. 60, 376). Dark-green tablets, decomposed by water.—4. With cuprous chloride and ammonia to form  $\text{CuCl}_2 \cdot \text{Cu}_2\text{Cl}_2 \cdot 4\text{NH}_3 \cdot \text{H}_2\text{O}$  (Ritthausen, J. pr. 60, 374); obtained by dissolving  $\text{Cu}_2\text{Cl}_2$  in  $\text{NH}_3\text{Aq}$ , allowing the solution

to become deep blue by exposure to air, and crystallising; or by the prolonged action of  $\text{NH}_4\text{ClAq}$  on Cu turnings at the ordinary temperature. Blue prisms; decomposed by water and alcohol; absorb O from air and lose  $\text{NH}_3$ ; when heated leave  $\text{Cu}_2\text{Cl}_2$ ; soluble in hot  $\text{HClAq}$  from which solution  $\text{CuCl}_2 \cdot 2\text{NH}_3 \cdot \text{Cl} \cdot 2\text{H}_2\text{O}$  crystallises out.—5. With ammonium chloride, to form (a)  $\text{CuCl}_2 \cdot 2\text{NH}_3 \cdot \text{Cl} \cdot 2\text{H}_2\text{O}$ , and (b)  $\text{CuCl}_2 \cdot \text{NH}_3 \cdot \text{Cl} \cdot 2\text{H}_2\text{O}$ . The former is obtained by crystallising a mixed solution of the two salts (Mitscherlich, J. pr. 19, 449; Graham, A. 29, 132); or by concentrating a mixed solution of  $\text{CuSO}_4$  and  $\text{NH}_4\text{Cl}$  (Vogel, J. pr. 2, 194); or saturating  $\text{CuCl}_2\text{Aq}$  with  $\text{NH}_3$  (Cap a. Henry, J. pr. 13, 184). Light-blue rhombic tables, or octahedra; loses all  $\text{H}_2\text{O}$  at  $110^\circ$ – $120^\circ$ ; S.G. 1.96 to 1.97. The salt  $\text{CuCl}_2 \cdot \text{NH}_3 \cdot \text{Cl} \cdot 2\text{H}_2\text{O}$  was obtained by Hantz (A. 66, 280), as blue-green crystals, by neutralising 1 part  $\text{HClAq}$  by  $\text{NH}_3$ , and 2 parts of the same  $\text{HClAq}$  by  $\text{CuCO}_3$ , mixing the solutions, and crystallising.—6. With potassium chloride to form  $\text{CuCl}_2 \cdot 2\text{KCl} \cdot 2\text{H}_2\text{O}$ ; obtained by evaporating a mixed solution of the two salts. S.G. 2.4.

**II. COPROUS CHLORIDE.**  $\text{Cu}_2\text{Cl}_2$ . (*Protochloride of copper*.) Mol. w. 197.14. V.D. (c.  $1560^\circ$ ) 6.8. Formula found to be  $\text{Cu}_2\text{Cl}_2$  and not  $\text{CuCl}$  from results of V.D. determinations by V. and O. Meyer, at c.  $1560^\circ$  (B. 12, 1112, 1233). [ $\text{Cu}^2, \text{Cl}^2$ ] = 65,750; [ $\text{Cu}_2\text{Cl}_2, \text{Cl}^2$ ] = 37,510 (Th. 8, 819).

**Formation.**—1. Cu is heated in Cl, keeping the Cu in excess.—2. Cu is heated to dull redness in a stream of  $\text{HCl}$  (Wöhler, A. 105, 360).—3. By heating together  $\text{CuCl}$  and Cu in  $\text{HClAq}$ .—4. By heating together Cu and  $\text{FeCl}_2\text{Aq}$ .—5. By heating  $\text{CuCl}_2$ .—6. By reducing  $\text{CuCl}_2\text{Aq}$  or  $\text{CuSO}_4\text{Aq}$  by  $\text{SnCl}_2$ , or  $\text{SO}_2$ .—7. By heating 2 parts  $\text{HgCl}_2$  with 1 part Cu turnings.—8. By heating  $\text{CuSO}_4$  with  $\text{NaH}_2\text{PO}_4$  in a little water (Cavazzi, G. 16, 167).

**Preparation.**—1. Sulphur dioxide is passed into a mixture of 1 part  $\text{NaCl}$  and  $2\frac{1}{2}$  parts  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  dissolved in water; the white pp. is washed with  $\text{SO}_4\text{Aq}$ , then with glacial acetic acid, pressed between paper, and dried at  $100^\circ$  (Wöhler, A. 130, 373; Rosenfeld, B. 12, 954). [ $2\text{CuCl}_2\text{Aq} + \text{H}_2\text{SO}_4 + \text{H}_2\text{O} = \text{Cu}_2\text{Cl}_2 + \text{H}_2\text{SO}_4\text{Aq} + 2\text{HClAq}$ ].—2. An intimate mixture of 14.2 parts powdered  $\text{CuO}$  with 7 parts zinc powder is thrown, little by little with constant shaking, into conc.  $\text{HClAq}$ , until a white pp. of  $\text{Cu}_2\text{Cl}_2$  begins to form; more acid is added, and then a little more of the mixture, and so on until the whole of the mixture has been used. The liquid is then poured into boiled water in a flask so that the flask is filled; the flask is closed; the  $\text{Cu}_2\text{Cl}_2$ , which separates as a shining white solid, is washed with distilled water, and dried in the dark (Heumann, B. 7, 720). [ $2\text{CuO} + \text{Zn} + 4\text{HClAq} = \text{Cu}_2\text{Cl}_2 + \text{ZnCl}_2\text{Aq} + 2\text{H}_2\text{O}$ ].

**Properties.**—Snow-white crystalline powder; insoluble in water, alcohol, dilute  $\text{HNO}_3$ , or  $\text{H}_2\text{SO}_4\text{Aq}$ ; soluble in hot  $\text{HClAq}$ , separating on cooling in tetrahedra; soluble in  $\text{NH}_3\text{Aq}$ ; soluble, on heating, in  $\text{KClAq}$ ,  $\text{NaClAq}$ ,  $\text{FeCl}_2\text{Aq}$ ,  $\text{ZnCl}_2\text{Aq}$ , and many other metallic chlorides; soluble in  $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$  when the two salts are in the ratio  $\text{Cu}_2\text{Cl}_2:\text{Na}_2\text{S}_2\text{O}_3$  (Winkler, J. pr. 68,

428). S.G. 3.7. Melts below red heat, and boils between 954° and 1033° (Carnelley & Williams, *C. J.* 37, 126). Solution in HClAq acts as an energetic reducer, converting HgCl<sub>2</sub> to HgCl, AuCl<sub>3</sub> to Au, decolorising Prussian blue, &c.; this solution rapidly absorbs CO (v. Hempel, *B.* 21, 898; cf. Drehschmidt, *B.* 21, 2158), colourless crystals of Cu<sub>2</sub>Cl<sub>2</sub>·CO·2H<sub>2</sub>O separate from a saturated solution of CO in Cu<sub>2</sub>Cl<sub>2</sub> (Berthelot, *A. Ch.* [3] 46, 488), on warming the solution CO escapes. This solution also absorbs various gases, e.g. C<sub>2</sub>H<sub>4</sub> and PH<sub>3</sub> (Riban, *B.* 12, 1208; Rose, *P.* 4, 110; 6, 205).

**Reactions.**—1. Moist Cu<sub>2</sub>Cl<sub>2</sub> changes in sunlight and air to yellow, violet, and then blue-black; an oxychloride is formed (Cu<sub>2</sub>Cl<sub>2</sub>·3CuO, according to Vogel, *D. P. J.* 136, 238) [concerning the action of sunlight on Cu<sub>2</sub>Cl<sub>2</sub>, v. Carlemann, *J. pr.* 63, 475].—2. Heated in oxygen or in water-vapour, CuO is formed.—3. By repeated washing with water CuCl and Cu<sub>2</sub>O are produced.—4. Reduced to Cu by hydrogen, or by digestion under water with iron filings.—5. Scarcely acted on by sulphuric acid, even when conc. and hot (Rosentfeld, *B.* 12, 954).—6. Reacts with many metallic sulphides to produce Cu<sub>2</sub>S (v. Raschig, *A.* 228, 1).

**Combinations.**—1. With ammonia to form Cu<sub>2</sub>Cl<sub>2</sub>·2NH<sub>3</sub>. By dissolving Cu<sub>2</sub>Cl<sub>2</sub> in NH<sub>3</sub>Aq; or better by boiling Cu turnings with conc. NH<sub>3</sub>ClAq until rapid evolution of NH<sub>3</sub> begins, filtering the boiling liquid into  $\frac{1}{2}$  its volume of water, and repeatedly filtering from Cu<sub>2</sub>O·xH<sub>2</sub>O, allowing to cool, repeatedly washing the solid which separates with alcohol and quickly pressing between paper (Ritthausen, *J. pr.* 59, 369, Millon & Commaillie, *C. R.* 56, 309). Colourless rhombic dodecahedra, becoming violet in air; decomposed by water into its constituents on heating; solution in water reduces ammoniacal silver solutions (M. & C.), it absorbs O from the air forming Cu<sub>2</sub>Cl<sub>2</sub>·CuCl<sub>2</sub>·4NH<sub>3</sub>·H<sub>2</sub>O (q. v. under COPPER CHLORIDE, Combinations, No. 4).—2. With sal ammoniac to form Cu<sub>2</sub>Cl<sub>2</sub>·4NH<sub>4</sub>Cl. Obtained by dissolving Cu<sub>2</sub>Cl<sub>2</sub>·2NH<sub>3</sub> in HClAq, or by adding a little NH<sub>3</sub>Aq to Cu<sub>2</sub>Cl<sub>2</sub> in HClAq; white crystals, becoming brown in air, and giving Cu<sub>2</sub>Cl<sub>2</sub> and NH<sub>4</sub>Cl when heated (Ritthausen, *J. pr.* 59, 369).—3. With potassium chloride to form Cu<sub>2</sub>Cl<sub>2</sub>·4KCl; large potahedra; prepared by dissolving Cu<sub>2</sub>Cl<sub>2</sub> in boiling KClAq, and allowing to cool in a closed vessel (Mitscherlich, *A. Ch.* 73, 384). A compound with NaCl is also known; it is very soluble and difficult to crystallise.—4. With phosphorus hydride, to form Cu<sub>2</sub>Cl<sub>2</sub>·2PH<sub>3</sub>. Obtained, as long colourless needles, by passing PH<sub>3</sub> into Cu<sub>2</sub>Cl<sub>2</sub> in HClAq until crystals form; when heated gives Cu phosphide, PH<sub>3</sub>, and HCl; water forms PH<sub>3</sub> and Cu<sub>2</sub>P (Riban, *Bl.* [2] 31, 335).

**Copper, Fluorides of.** Two fluorides have been isolated, CuF<sub>2</sub> and Cu<sub>2</sub>F<sub>2</sub> (Berzelius, *P.* 1, 28).

I. **CUPRIC FLUORIDE**, CuF<sub>2</sub>·2H<sub>2</sub>O. Best obtained by dissolving CuCO<sub>3</sub> in HFaq, and adding alcohol of 95 p.c. (Balbiano, *G.* 14, 74). Pale-blue crystalline powder; sparingly soluble in water, very easily decomposed to oxyfluoride CuF<sub>2</sub>·Cu(OH)<sub>2</sub> = CuF.OH (v. OXYFLUORIDE under COPPER, OXYALOID COMPOUNDS OF). Decomposes on keeping for four or five days with evolution of

HF. Combines with KF to form very soluble CuF<sub>2</sub>·2KF. Absorbs NH<sub>3</sub> with formation of CuF<sub>2</sub>·Cu(OH)<sub>2</sub>·4NH<sub>3</sub>·2H<sub>2</sub>O (Balbiano, *l.c.*).

**Cupric borofluoride** Cu(BF<sub>4</sub>)<sub>2</sub> = CuF<sub>2</sub>·2BF<sub>3</sub> is obtained by mixing Ba(BF<sub>4</sub>)<sub>2</sub> and CuSO<sub>4</sub>Aq.

**Cupric silicofluoride** CuSiF<sub>6</sub>·6H<sub>2</sub>O is produced by dissolving CuO in H<sub>2</sub>SiF<sub>6</sub>Aq and evaporating.

II. **CUPROUS FLUORIDE**, Cu<sub>2</sub>F<sub>2</sub>. A red powder obtained by treating Cu<sub>2</sub>O·xH<sub>2</sub>O with HFaq; washing with water, pressing, and drying *in vacuo*; decomposed by moist air to Cu(OH)<sub>2</sub>·CuF<sub>2</sub> (Berzelius, *l.c.*).

**Copper, Hydride of.** A compound of Cu and H is said to be produced by the following reactions:—1. 1 pt. Ba(H<sub>2</sub>PO<sub>3</sub>)<sub>2</sub> is dissolved in water, the Ba is exactly pptd. by H<sub>2</sub>SO<sub>4</sub>Aq, the filtrate is added to 8 parts CuSO<sub>4</sub>·5H<sub>2</sub>O in rather dilute solution, at the ordinary temperature, ppn. is allowed to proceed slowly; the pp. is washed with air-free water in an atmosphere of CO<sub>2</sub>, and dried by pressure between paper (Wurtz, *A. Ch.* [3] 11, 250; *C. R.* 89, 1056; 90, 22).—2. NaHSO<sub>4</sub>Aq is added in excess to CuSO<sub>4</sub>Aq; if the CuSO<sub>4</sub> is in excess the pp. contains some Cu (Schutzenberger, *C. R.* 69, 195).—3. Zinc is placed in CuSO<sub>4</sub>Aq acidulated with H<sub>2</sub>SO<sub>4</sub> (Schoor, *Ar. N.* 12, 96; [*J.* 1877. 273]).—4. A moderately strong current is passed through very dilute slightly acidulated CuSO<sub>4</sub>Aq; the compound forms at the negative pole but begins to decompose, with evolution of H<sub>2</sub>, as soon as the current is stopped (Poggendorff, *P.* 75, 337). Copper hydride is described as a reddish-brown powder, having the composition Cu<sub>2</sub>H<sub>2</sub>; it decomposes at 60° into Cu and H<sub>2</sub>; in HClAq it gives Cu<sub>2</sub>Cl<sub>2</sub> and H<sub>2</sub>; it takes fire in Cl<sub>2</sub> (Cf. Berthelot [*C. R.* 89, 1005, 1097], who says that the so-called copper hydride always contains O, H<sub>2</sub>O, and P; but Wurtz [*C. R.* 69, 22] gives further details and analyses, showing that the preparation is apt to contain Cu phosphatid, but the presence of more than a mere trace of this may be avoided by ppg. the Cu<sub>2</sub>H<sub>2</sub> very slowly in cold solutions).

**Copper, Hydroxides of, v. HYDRATED OXIDES OF COPPER, under COPPER, OXIDES OF.**

**Copper, Iodides of.** Only one iodide of copper has been isolated; this is the cuprous compound, Cu<sub>2</sub>I<sub>2</sub>. When KIaq is added to the solution of a cupric salt, a pp. of Cu<sub>2</sub>I<sub>2</sub> mixed with free I is obtained; e.g. 2CuSO<sub>4</sub>Aq + 4KIaq = Cu<sub>2</sub>I<sub>2</sub> + I<sub>2</sub> + 2K<sub>2</sub>SO<sub>4</sub>Aq. Cu<sub>2</sub>I<sub>2</sub> dissolves in alcoholic solution of I; the liquid is not pptd. by water, but on heating and adding alcoholic solution of KI, Cu<sub>2</sub>I<sub>2</sub> is pptd. along with KI. Solutions containing about 8 gram CuI<sub>2</sub> per 100 c.c. have been obtained; compounds are known which probably contain CuI<sub>2</sub> (v. *infra*).

**Cuprous iodide**, Cu<sub>2</sub>I<sub>2</sub>. S.G. 4.41 (Schiff). B.P. between 759° and 772° (Carnelley & Williams, *C. J.* 37, 126). Mol. w. not determined, but from analogy of Cu<sub>2</sub>Cl<sub>2</sub> it is probably Cu<sub>2</sub>I<sub>2</sub> = 379.48. [Cu<sup>+</sup>, I<sup>-</sup>] = 85,200 (*Th.* 3, 819).

**Formation.**—1. v. Finely divided Cu heated with I forms Cu<sub>2</sub>I<sub>2</sub>; a plate of Cu exposed to the vapour of I becomes covered with crystals of Cu<sub>2</sub>I<sub>2</sub> (Rensault, *C. R.* 59, 819).—2. Cu is dissolved in conc. HIAq, on standing in air (or better on adding a trace of H<sub>2</sub>S) Cu<sub>2</sub>I<sub>2</sub> ppts. in

crystals (Rose, *P.* 4, 110).—8.  $\text{Cu}_2\text{S}$  is dissolved in conc.  $\text{HIAq}$  (Mensel, *B.* 3, 123).—4.  $\text{KIAq}$  is added to  $\text{CuSO}_4\text{Aq}$ ;  $\text{Cu}_2\text{I}_2$  is ppd. along with  $\text{I}$ .

**Preparation.**— $\text{CuSO}_4\text{Aq}$  is saturated with  $\text{SO}_2$ , or a mixture of 1 pt.  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  and  $2\frac{1}{2}$  pts.  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  is dissolved in water,  $\text{KIAq}$  is added, the pp. is washed and dried (Duflos, *A.* 39, 253; Soubeiran, *J. Ph.* 13, 427).

**Properties and Reactions.**—A white, or brownish-white, crystalline powder; insoluble in water, alcohol, and dilute acids; soluble in  $\text{KIAq}$ , and in  $\text{NH}_4\text{Aq}$  in presence of air. Soluble in hot conc.  $\text{HClAq}$  and reppd. on addition of water. Decomposed by conc.  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$ . Heated with  $\text{MnO}_2$  or  $\text{KClO}_3$ ,  $\text{CuO}$  is formed; reduced to  $\text{Cu}$  by boiling with water and  $\text{Zn}$ ,  $\text{Sn}$ , or  $\text{Fe}$  (Berthémot, *J. Ph.* 15, 445). When  $\text{Cu}_2\text{I}_2$  is dissolved in  $\text{NH}_4\text{Aq}$  by heating in an open vessel, colourless crystals of  $\text{Cu}_2\text{I}_2 \cdot 4\text{NH}_3$  separate on cooling, and the mother liquor on addition of alcohol deposits a dark-blue compound  $\text{Cu}_2\text{I}_2 \cdot 4\text{NH}_3 \cdot \text{H}_2\text{O}$  (Rammelsberg, *P.* 48, 162; v. also Berthémot, *J. Ph.* 15, 445; and Saglier, *C. R.* 102, 1552).  $\text{Cu}_2\text{I}_2$  dissolves in alcoholic  $\text{I}$ ; when this liquid is heated to  $80^\circ$ , and mixed with alcoholic  $\text{NH}_3$  at  $30^\circ$ , crystals separate in a few hours having the composition  $\text{Cu}_2\text{I}_2 \cdot 4\text{NH}_3 \cdot \text{I}_2$  (Jørgensen, *J. pr.* [2] 2, 353).

**Combinations.**—1. With ammonia to form  $\text{Cu}_2\text{I}_2 \cdot 4\text{NH}_3$  (Rammelsberg, *P.* 48, 162). Obtained by passing  $\text{NH}_3$  over  $\text{Cu}_2\text{I}_2$ ; white, lustrous crystals; decomposed by heat to  $\text{Cu}_2\text{I}_2$  and  $\text{NH}_3$ . The same compound is formed by mixing  $\text{KIAq}$  with an ammoniacal solution of a cuprous salt in absence of air; as thus obtained the compound cannot be dried without losing  $\text{NH}_3$  (Levol, *N. J. P.* 4, 328).—2. With ammonium iodide; the compound  $\text{Cu}_2\text{I}_2 \cdot 2\text{NH}_4\text{I} \cdot \text{H}_2\text{O}$  is obtained, as white needles, by dissolving 100 gs.  $\text{NH}_4\text{I}$  in 1,000 gs. water, adding 10–15 gs.  $\text{Cu}(\text{OH})_2$ , heating until all is dissolved, boiling with a large excess of  $\text{Cu}$  until the liquid is colourless, and allowing to cool. The mother liquor in air deposits black crystals of  $\text{Cu}_2\text{I}_2 \cdot 2\text{NH}_4\text{I} \cdot 2\text{H}_2\text{O}$ . These crystals are very unstable (Saglier, *C. R.* 104, 1440).—3. With ammonia and cupric iodide; when 100 gs. of an ammoniacal solution of  $\text{CuO}$ , containing 7–8 p.c.  $\text{CuO}$ , is mixed with an equal mass of 10 p.c. alcoholic  $\text{I}$  solution, warmed until the pp. of  $\text{NI}_2$  dissolves, heated in the water bath for an hour, and allowed to cool, brilliant green crystals are deposited of the composition  $\text{Cu}_2\text{I}_2 \cdot 4\text{NH}_3$ , probably =  $\text{Cu}_2\text{I}_2 \cdot \text{Cu}_2\text{I}_2 \cdot 4\text{NH}_3$  (Saglier, *C. R.* 102, 1552).—4. With silver iodide to form a series of bodies resembling alloys;  $\text{Cu}_2\text{I}_2 \cdot x\text{AgI}$ ,  $x$  varying from 1 to 12; for physical constants of these bodies v. Rodwell, *Pr.* 33, 143; Bellati a. Romanese, *Pr.* 34, 104. According to Guyard (*Bl.* [2] 41, 12) a double iodide of  $\text{Cu}$  and  $\text{N}$  is produced when an alkaline di-iodide is added to an ammoniacal  $\text{Cu}$  solution.

**II. Cupric iodide.** Cupric iodide,  $\text{CuI}_2$ , has not been isolated. A solution of  $\text{Cu}_2\text{I}_2$  in alcoholic  $\text{I}$  is not ppd. by water, but on heating and adding alcoholic  $\text{KI}$ ,  $\text{Cu}_2\text{I}_2$  is reppd. along with  $\text{KI}$ , the solution may perhaps contain a periodide of  $\text{Cu}$  (Jørgensen, *J. pr.* [2] 2, 347).  $\text{Cu}_2\text{I}_2$  in presence of  $\text{I}$  dissolves in much water; this solution probably contains  $\text{CuI}_2$  (Traube, *B.* 17, 1064). Carnegie (*priv. comm.*) has obtained aqueous solutions of cupric iodide containing ca. 0.8 g.

Vol. II.

$\text{CuI}_2$  in 100 c.c., by digesting  $\text{Cu}_2\text{I}_2$  with  $\text{I}$  in water at  $80^\circ$  for a few minutes, cooling, shaking for a short time with  $\text{Cu}$  foil or  $\text{CS}_2$  to remove excess of  $\text{I}$ . Solution of  $\text{CuI}_2$  containing c. 9 g.  $\text{CuI}_2$  with excess of  $\text{I}$  is very easily decomposed, almost anything that removes the  $\text{I}$  at the same time decomposes the  $\text{CuI}_2$  to  $\text{CuI}$  and  $\text{I}_2$ , e.g. starch or  $\text{Ag}$  leaf; the solution partially decomposes when boiled out of contact with air, also when a current of air,  $\text{N}$ , or other indifferent gas, is passed through it, and even when kept *in vacuo* at the ordinary temperature. Solutions of  $\text{CuI}_2$  are also obtained by digesting  $\text{CuO} \cdot \text{H}_2\text{O}$ , or  $\text{CuCO}_3$ , with fairly conc.  $\text{HIAq}$  saturated with  $\text{I}$ , and filtering from excess of  $\text{CuO} \cdot \text{H}_2\text{O}$ , or  $\text{CuCO}_3$ . Potassium iodide withdraws  $\text{I}$  from solutions of  $\text{CuI}_2$ , ppd.  $\text{CuI}$ ; when  $\text{KI}$  interacts with a cupric salt in molecular proportions,  $\text{CuI}_2$  is almost certainly produced, but as the change is not complete the residual  $\text{KI}$  interacts with the  $\text{CuI}_2$  in solution to produce  $\text{CuI}$  and  $\text{KI} \cdot \text{I}$ . Thomsen gives  $[\text{CuI}_2\text{Aq}] = 10,410$  (*Th.* 3, 320).

Various compounds are known, one constituent of each of which is probably  $\text{CuI}_2$ . The formation of the compounds  $\text{CuI}_2 \cdot 4\text{NH}_3 \cdot \text{H}_2\text{O}$ , and  $\text{CuI}_2 \cdot \text{Cu}_2\text{I}_2 \cdot 4\text{NH}_3$  has been described (v. Cuprous iodide, *Reactions*, also *Combinations*, No. 3). The compound  $\text{CuI}_2 \cdot 4\text{NH}_3 \cdot \text{I}_2$  was obtained by Jørgensen (*J. pr.* [2] 2, 353) as blue crystals, by mixing solutions of  $\text{I}$  in  $\text{KI}$  and  $\text{Cu} \cdot \text{NH}_3$  nitrate, at  $50^\circ$ , and filtering hot into water at  $50^\circ$  (v. also Saglier, *C. R.* 102, 1552). Saglier (*C. R.* 104, 1440) describes the compounds  $\text{CuI}_2 \cdot 2\text{NH}_4\text{I} \cdot 2\text{H}_2\text{O}$ , and  $\text{CuI}_2 \cdot 4\text{NH}_3 \cdot \text{H}_2\text{O}$ , produced by boiling  $\text{NH}_4\text{IAq}$  with  $\text{Cu}(\text{OH})_2$ ; he also describes a compound with  $(\text{NH}_4)_2\text{I}_2$ , viz.  $\text{CuI}_2 \cdot 2\text{NH}_4\text{I} \cdot 2\text{NH}_4\text{I} \cdot 6\text{H}_2\text{O}$ , obtained by dissolving  $\text{Cu}(\text{OH})_2$  in hot  $\text{NH}_4\text{IAq}$ .

Carnegie (*priv. comm.*) has obtained the compound  $\text{CuO} \cdot 2\text{CuI}_2 \cdot 4\text{H}_2\text{O}$  by partially immersing slips of  $\text{Cu}$  in  $\text{BaI}_2\text{Aq}$ ; black crystals slowly form on the sides of the vessel; they are easily decomposed by washing with water; they may be washed with alcohol and dried over  $\text{CaCl}_2$ .

**Copper, Nitride of.**  $\text{Cu}_3\text{N}$ . When finely divided  $\text{CuO}$ , ppd. from hot  $\text{CuSO}_4\text{Aq}$  by  $\text{KOH}$ , is heated in a tube to  $250^\circ$  and dry  $\text{NH}_3$  is passed over it, greenish-black copper nitride is formed; if the solid is powdered from time to time and the passage of  $\text{NH}_3$  is continued, the whole of the  $\text{CuO}$  may be changed to nitride. Copper nitride decomposes by heating to about  $300^\circ$ , giving  $\text{Cu}$  and  $\text{N}$ ; in  $\text{Cl}$  it gives  $\text{CuCl}$ , and  $\text{N}$ ; in  $\text{HClAq}$ ,  $\text{CuCl}$ , and  $\text{NH}_4\text{Cl}$  are formed; it is oxidised rapidly by  $\text{HNO}_3\text{Aq}$ , and decomposed to  $\text{Cu}$  and  $\text{N}$  by  $\text{H}_2\text{SO}_4\text{Aq}$  (Schrötter, *A.* 37, 136; v. also Warren, *C. N.* 55, 155). By heating to bright redness discs of  $\text{Cu}$  and  $\text{Pt}$  placed 8–4 mm. apart in an atmosphere of  $\text{N}$ , Blondlot got indications of the formation of a compound of  $\text{Cu}$  and  $\text{N}$ ; but he did not isolate the compound (*C. R.* 102, 210). According to Schrötter (*loc. cit.*)  $\text{Cu}$  and  $\text{N}$  do not directly combine.

**Copper, Oxides of.** Copper forms four oxides;  $\text{Cu}_2\text{O}$ ,  $\text{Cu}_3\text{O}$ ,  $\text{CuO}$ , and  $\text{Cu}_2\text{O}_2$ . There are indications of the existence of other oxides, but none has been certainly isolated. The best-studied are  $\text{Cu}_2\text{O}$  and  $\text{CuO}$ ; both are basic, and each forms a series of corresponding salts, those corresponding to  $\text{CuO}$  being the more stable. The oxide  $\text{Cu}_2\text{O}$  reacts with acids to form  $\text{Cu}$  and

a salt, in some cases a cuprous, and in other cases a cupric, salt. The oxide  $\text{Cu}_2\text{O}$  reacts with acids as a basic peroxide, forming cupric salts and oxygen. Any oxide other than  $\text{CuO}$  is changed into  $\text{CuO}$  by heating in air or oxygen. By adding solution of bleaching powder to  $\text{Cu}_2\text{NO}_3\text{Aq}$ , a pp. is obtained which soon decomposes with evolution of  $\text{O}$ ; this pp. is possibly a salt the acidic radicle of which is composed of  $\text{Cu}$  and  $\text{O}$  (v. p. 260). No oxide of  $\text{Cu}$  has been gasified, hence the formulæ given are not necessarily molecular.

**I. COPPER SUBOXIDE  $\text{Cu}_2\text{O}$ .** (*Quadrifide of copper*) (Rose, P. 120, 1). An olive-green powder; stable under water in absence of  $\text{O}$ , but rapidly oxidised in air to  $\text{Cu}_2\text{O}$  and then to  $\text{CuO}$ ; decomposed by dilute  $\text{HClAq}$  to  $\text{Cu}_2\text{Cl}_2$  and  $\text{Cu}$ , and by dilute  $\text{H}_2\text{SO}_4\text{Aq}$  to  $\text{CuSO}_4$  and  $\text{Cu}$ ; insoluble in  $\text{NH}_3\text{Aq}$ , and in a mixture of  $\text{NH}_3\text{Aq}$  and  $(\text{NH}_4)_2\text{CO}_3\text{Aq}$ . Prepared by reaction between  $\text{CuSO}_4\text{Aq}$  and  $\text{SnCl}_2$  in presence of  $\text{KOH}$ ;  $\text{Cu}(\text{OH})_2$  is first precipitated and then reduced with simultaneous formation of  $\text{K}$  stannate:  $4\text{Cu}(\text{OH})_2 + 12\text{KOH} + 3\text{SnCl}_2 = \text{Cu}_2\text{O} + 6\text{KClAq} + 3\text{K}_2\text{SnO}_3 + 10\text{H}_2\text{O}$ . To prepare this oxide, Rose directs to make 300 c.c.  $\text{CuSO}_4\text{Aq}$  containing 10 g.  $\text{Cu}$ ; to add this to 1,000 c.c. of a solution of 50 g.  $\text{SnCl}_2$  in  $\text{KOH}$   $\text{Aq}$ , and to shake in a well-closed vessel which is completely filled with the liquid, keeping cool by water; to filter after twenty-four hours in an atmosphere of  $\text{H}$ , and wash the pp. with water containing  $\text{KOH}$ , then with water, then with very dilute  $\text{NH}_3\text{Aq}$ , and finally with water. It is difficult to obtain  $\text{Cu}_2\text{O}$  free from the other oxides. (For precautions v. Rose, l.c.)

**II. CUPROUS OXIDE  $\text{Cu}_2\text{O}$ .** (*Hemi-oxide of copper. Protoxide of copper. Red oxide of copper.*) S.G.  $\frac{1}{2}$  5.749 (native), 5.345–5.375 (artificial). H.F. [ $\text{Cu}_2\text{O}$ ] = 40,810 (Th. 3, 320). Occurs native as *Cuprite*, in lustrous, red, octahedra.

**Formation.**—1. By heating  $\text{Cu}$  in air; the outer film thus formed is  $\text{CuO}$ , beneath this is a film of  $\text{Cu}_2\text{O}$ . Finely divided  $\text{Cu}$  (obtained by reducing  $\text{CuO}$  in  $\text{H}$  at a moderate temperature) oxidises in air to  $\text{Cu}_2\text{O}$  (Berzelius, A. 61, 1; v. also Mitscherlich, J. pr. 19, 450; and Marchand, J. pr. 20, 505).—2. By heating  $\text{Cu}$  turnings with  $\text{CuO}$  (Berzelius), or with dehydrated  $\text{CuSO}_4$  (Ullgren, P. 55, 527), or with  $\text{CuSO}_4$  and  $\text{Na}_2\text{CO}_3$  (Malaguti, J. pr. 2, 167).—3. By heating  $\text{Cu}_2\text{Cl}_2$  with  $\text{Na}_2\text{CO}_3$  (Wöhler a. Liebig, P. 21, 581).—4. By the reaction of  $\text{Cu}$  with  $\text{Cu}_2\text{NO}_3$  and a little  $\text{CuO}$ , in absence of air (Becquerel, A. Ch. 41, 228).—5. By the prolonged action of  $\text{NH}_3\text{Aq}$  on a mixture of  $\text{CuSO}_4\text{Aq}$  and  $\text{FeSO}_4\text{Aq}$  in presence of  $\text{Fe}(\text{OH})_3$  (Wibel, *Reduction von Kupferoxydsalzen* [Hamburg, 1864], 2).

**Preparation.**—1. 5 pts.  $\text{Cu}_2\text{Cl}_2$  are heated with 3 pts. dehydrated  $\text{Na}_2\text{CO}_3$ , the resultant mass is washed with water (W. a. L., P. 21, 581).—2. A mixture of 1 pt.  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ , 1½ pts. cream of tartar, 2 pts. grape sugar, in 12 pts. water, is heated in a basin; 1½ pts.  $\text{NaOH}$  are added, and the whole is boiled until the supernatant liquid is colourless; the pp. is washed with water, then with alcohol, and dried (Böttger, D. P. J. 171, 77).—3. An intimate mixture of equal parts  $\text{CuO}$  and  $(\text{NH}_4)_2\text{CO}_3$  is heated over a Bunsen-burner till the smell of  $\text{NH}_3$  is no longer apparent (Schiff, W. J. 1864, 274).

**Properties.**—A carmine-red crystalline powder. Melts at full red heat and oxidises to  $\text{CuO}$ . Soluble in  $\text{NH}_3\text{Aq}$ , forming a colourless liquid which becomes blue in the air, and reacts as a strong reducing agent.

**Reactions.**—1. *Hydrochloric acid* forms  $\text{Cu}_2\text{Cl}_2$ , soluble in excess of the acid [ $\text{Cu}_2\text{O} \cdot 2\text{HClAq}$ ] = 14,660 (Th. 3, 320).—2. *Dilute acids*, e.g.  $\text{H}_2\text{SO}_4\text{Aq}$ ,  $\text{HNO}_3\text{Aq}$ ,  $\text{H}_3\text{PO}_4\text{Aq}$ ,  $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$ , produce  $\text{Cu}$  and cupric salts.—3. *Conc. nitric acid* forms  $\text{Cu}_2\text{NO}_3$ .—4. *Bromine water* forms  $\text{CuBr}_2$  and  $\text{CuO}$ .—5. Reduced to  $\text{Cu}$  by *hydrogen*, *potassium*, or *carbon*.—6. *Sulphur* forms  $\text{Cu}_2\text{S}$ .—7. Many *metallic chlorides* in solution, e.g.  $\text{MgCl}_2\text{Aq}$ ,  $\text{ZnCl}_2\text{Aq}$ , form soluble double salts and also ppt. hydrated oxides of the metals.—8. *Ferric chloride* solution produces  $\text{Fe}_2\text{O}_3$ ,  $\text{Cu}$ , and  $\text{Cu}_2\text{Cl}_2$ .—9. From neutral *silver solution*  $\text{Cu}_2\text{O}$  ppts. a mixture of  $\text{Ag}$  and a basic cupric salt.

**HYDRATED CUPROUS OXIDE  $\frac{1}{2}\text{Cu}_2\text{O} \cdot \text{H}_2\text{O}$ .** Produced, as a yellowish powder, by adding an alkali or alkaline carbonate to the solution of a cuprous salt (Fremy, A. Ch. [3] 23, 391). Also formed by heating to boiling moist  $\text{Cu}(\text{OH})_2$  with milk sugar and some  $\text{Na}_2\text{CO}_3\text{Aq}$ . According to Mitscherlich (J. pr. 19, 450) the hydrate loses its water at  $360^\circ$ . Oxidises in air to  $\text{Cu}(\text{OH})_2$  (v. also *Gm.-K.* [6th ed.] 3, 595; Millon a. Commaillie, C. R. 57, 145; Field, C. J. [2] 1, 28; P. de Saint-Gilles, A. Ch. [3] 42, 36). Dissolves in dilute acids to form cuprous salts, very few of which have been isolated.

**III. CUPRIC OXIDE  $\text{CuO}$ .** (*Black oxide of copper. Copper oxide.*) S.G. 6.1 to 6.4 (Boullay, A. Ch. [2] 43, 266; Playfair a. Joule, C. S. Mem. 3, 57). H.F. [ $\text{CuO}$ ] = 37,160 (Th. 3, 320). Occurs native in North America as *Melakonite*. Crystallises in monoclinic forms;  $a:b:c = 1.49:1:1.36$  (Maskelyne, Z. A. 1865).

**Formation.**—1. By heating  $\text{Cu}$  in air or  $\text{O}$ , removing the scales which form, and strongly heating in air.—2. By heating  $\text{Cu}_2\text{NO}_3$ ,  $\text{Cu}(\text{OH})_2$ ,  $\text{CuCO}_3$ , or very strongly heating  $\text{CuSO}_4$ .

**Preparation.**—1. Pure  $\text{Cu}$ , prepared by electrolysis, is dissolved in  $\text{HNO}_3\text{Aq}$  to one-half of the solution  $\text{NH}_3\text{Aq}$  is added until the pp. which forms has just dissolved, the other half of the liquid is then added, the whole is evaporated to dryness, and the  $\text{Cu}$  nitrate thus obtained is strongly heated; the oxide thus formed is well washed, and again heated in a Pt dish (Reischauer, J. 1863, 274; Erdmann a. Marchand, J. pr. 31, 389). The oxide must not be too strongly heated else it partially fuses and contains  $\text{Cu}_2\text{O}$ ; according to Thudichum a. Kingzett (C. J. [2] 15, 363) the oxide should be heated *in vacuo* to remove traces of  $\text{CO}_2$ .—2. A solution of equivalent masses of  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  and  $\text{Na}_2\text{CO}_3$  is evaporated to dryness and the residue is heated strongly in a crucible and then well washed; moist air is then passed over the heated oxide to remove traces of chlorides (Stanford, C. N. 7, 81; Erlenmeyer, Z. 1863, 157). The oxide as thus prepared is specially adapted for use in organic analysis.—3. The oxide is obtained in crystals by dropping  $\text{Cu}_2\text{Cl}_2$  in small successive quantities into a red hot Pt crucible (Schulze, J. pr. [2] 21, 418); Becquerel (A. Ch. 51, 122) obtained crystals of  $\text{CuO}$  by heating to dull redness

5 grams amorphous CuO with 2-3 grams pure KOH, washing with water, and separating the crystals by shaking.

**Properties.**—Brown-black amorphous powder; or metal-like, lustrous, monoclinic crystals. Hygroscopic (*v. Rentzsch, J. pr.* [2] 21, 413). Slightly volatile in a porcelain-oven (Elsner, *J.* 1866, 35). Said to lose O when strongly heated giving  $\text{Cu}_2\text{O}$  (Favre & Mauméné, *C. R.* 18, 658). According to Reischauer (*J.* 1859, 216) Cu<sub>2</sub>O is formed by very strongly heating CuO; this is confirmed by Debray and Joannis (*C. R.* 99, 583) provided the heating is conducted *in vacuo*. According to Joannis (*C. R.* 102, 1157) CuO prepared at a high temperature develops less heat when dissolved in HClAq than specimens prepared at a low temperature. CuO is a basic oxide reacting with acids to form cupric salts  $\text{CuX}_2$  [ $\text{X} = \text{NO}_3$ ,  $\frac{\text{SO}_4}{2}$ , &c.]; it dissolves in much KOHAq, and perhaps forms salts in which CuO acts as an acidic radical.

**Reactions.**—1. Easily reduced to Cu by heating in hydrogen or carbon monoxide, or with carbon or carbon compounds [hence its use in organic analysis] (for temperatures at which reduction in H and CO begins *v. Wright & Luff, C. J.* 33, 1).—2. Heated with copper forms Cu<sub>2</sub>O.—3. Heated with phosphorus, phosphide and phosphate of Cu are formed.—4. Heated with sulphuretted hydrogen, or with sulphur in a stream of hydrogen, Cu<sub>2</sub>S is formed (Rose, *P.* 110, 120).—5. Heated with sulphur alone gives Cu<sub>2</sub>S and SO<sub>2</sub> if S is in excess, or Cu<sub>2</sub>O and CuSO<sub>4</sub> if CuO is in excess (Jordan, *J. pr.* 28, 222).—6. Heated with sal ammoniac Cu<sub>2</sub>Cl<sub>2</sub> and a little CuCl are formed.—7. Heating with ferric chloride produces Fe<sub>2</sub>O<sub>3</sub> with CuCl and Cu<sub>2</sub>Cl<sub>2</sub> (Hunt, *C. R.* 69, 1357).—8. Reacts with zinc chloride solution to produce a green powder Zn<sub>2</sub>Cu<sub>2</sub>Cl<sub>6</sub>H<sub>2</sub>O (André, *C. R.* 106, 854).—9. Soluble in ammonia, also in molten potash.—10. Acids dissolve CuO with formation of cupric salts: Thomsen gives the following thermal data ( $\text{M} = \text{CuO}$ ): [ $\text{M}, 2\text{HClAq}$ ] = 15,270; [ $\text{M}, \text{H}^+\text{SO}^+\text{Aq}$ ] = 18,800; [ $\text{M}, 2\text{HNO}^+\text{Aq}$ ] = 15,250; [ $\text{M}, 2\text{HClO}^+\text{Aq}$ ] = 15,910; [ $\text{M}, 2\text{C}^+\text{H}^+\text{O}^+\text{Aq}$ ] = 13,180; [ $\text{M}, \text{SO}^+$ ] = 42,170; [ $\text{Cu}_2\text{O}, \text{H}^+\text{SO}^+\text{Aq}$ ] = 55,960; [ $\text{Cu}_2\text{O}, 2\text{HNO}^+\text{Aq}$ ] = 52,410.

**Combinations.**—1. With water to form CuO.H<sub>2</sub>O, produced indirectly, *v. infra*.—2. With water and ammonia to form  $x\text{CuO} \cdot y\text{NH}_3 \cdot z\text{H}_2\text{O}$ . CuO dissolves in NH<sub>3</sub>Aq in presence of air, especially if a small quantity of an NH<sub>3</sub> salt is present (Berzelius). Kane (*A. Ch.* [2] 72, 283) obtained the compound  $3\text{CuO} \cdot 4\text{NH}_3 \cdot 6\text{H}_2\text{O}$  by adding NH<sub>3</sub>Aq to CuCl<sub>2</sub>Aq. Malaguti & Sargeau (*A. Ch.* [3] 9, 438) obtained CuO.4NH<sub>3</sub>.4H<sub>2</sub>O by treating with NH<sub>3</sub> the mother-liquor from the preparation of Cu-NH<sub>3</sub> chromate. A solution of CuO in NH<sub>3</sub>Aq dissolves cellulose; the solution is conveniently prepared either by digesting Cu spirals with NH<sub>3</sub>Aq in air, or by ppg. CuSO<sub>4</sub>Aq by the calculated quantity of NaOHAq, washing the pp. of Cu(OH)<sub>2</sub> and dissolving it in NH<sub>3</sub>Aq (Schweizer, *J. pr.* 72, 109). Ammoniacal solutions of CuO are reduced with ppn. of Cu, by P, Zn, Co, &c.—4. With a few metallic oxides to form compounds of the type CuO.xM<sub>2</sub>O<sub>3</sub>; e.g. CuO.Fe<sub>2</sub>O<sub>3</sub>, formed by heating together the two oxides (List, *B.* 11, 1516), or by the reaction of CuO with Fe<sub>2</sub>Cl<sub>3</sub>Aq,

or by ppg. by KOHAq a solution of equivalent masses of a Cu and a ferric salt. The compound  $3\text{CuO} \cdot \text{Mn}_2\text{O}_3$  is obtained by adding NaOH to an ammoniacal solution of CuO, and then MnCl<sub>2</sub>Aq drop by drop with constant stirring (Schneider, *Am.* 9, 269). The compound CuO.Cr<sub>2</sub>O<sub>3</sub> is described by Persoz (*A. Ch.* [3] 25, 283).

**HYDRATED CUPRIC OXIDE OR COPPER HYDROXIDE**  
 $\text{CuO} \cdot \text{H}_2\text{O} = \text{Cu}(\text{OH})_2$ .

**Preparation.**—Obtained by adding dilute NaOHAq or KOHAq in slight excess to CuSO<sub>4</sub>Aq; or preferably by adding CuSO<sub>4</sub>Aq to NaOHAq, keeping the latter in excess (Oglialoro, *J.* 1876, 217); washing very many times, and drying at a low temperature. Böttger (*J. pr.* 73, 491) recommends to drop NH<sub>3</sub>Aq into boiling CuSO<sub>4</sub>Aq until the pp., which at first is greenish, becomes blue, to wash this pp. thoroughly, and then to add fairly conc. NaOHAq, keeping the temperature about 20°-40° (*v. also Löwe, D. P. J.* 149, 270; Péligot, *C. R.* 53, 209).

**Properties.**—A blue solid, sometimes crystalline, very easily dehydrated. Heated in presence of water it turns black, the change occurring more readily if KOH or NaOH is present; the black compound is  $3\text{CuO} \cdot \text{H}_2\text{O}$  according to Harms (*J.* 1857, 246),  $6\text{CuO} \cdot \text{H}_2\text{O}$  according to Rose (*P.* 84, 480). When heated to 100° it loses water, but it is not fully dehydrated even at 200°-300° according to Rose (*l.c.*; cf. Schaffner, *A.* 51, 168). The hydrate is soluble in acids, also in NH<sub>3</sub>Aq, and in solutions of NH<sub>3</sub> salts; also in Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>Aq (Field, *C. J.* [2] 1, 28).

**Reactions.**—1. With ferrous hydroxide produces Fe<sub>2</sub>O<sub>3</sub>H<sub>2</sub> and Cu<sub>2</sub>O.xH<sub>2</sub>O (Levol, *A. Ch.* 65, 320).—2. With ferrous sulphate solution produces Cu<sub>2</sub>O.xH<sub>2</sub>O and basic ferric sulphate (Braun, *J.* 1867, 301).—3. Dissolves in acids to form cupric salts.—4. Dissolves in 4 to 6 parts molten potash; on adding water CuO is formed, but some of the Cu remains in solution, and on adding a large excess of KOHAq all dissolves.—5. Dissolves in large excess of potash solution to a blue liquid; according to Chodnew (*J. pr.* 28, 217) this liquid remains blue on boiling or on adding much water, but on standing in air for a long time a part of the Cu in solution is ppd. as CuO.H<sub>2</sub>O; addition of HClAq to the blue liquid until nearly neutral pppts. Cu(OH)<sub>2</sub>, but a little Cu remains in solution. Chodnew (*l.c.*) also states that addition of a large excess of KOHAq to CuSO<sub>4</sub>Aq or Cu(NO<sub>3</sub>)<sub>2</sub>Aq causes some of the Cu(OH)<sub>2</sub> to dissolve; the solutions must be cold and dilute; the whole of the Cu is not ppd. on boiling. The hydrate dissolves in NaOHAq (70 p.c.), and gives a blue pp. on long standing, containing CuO and Na<sub>2</sub>O according to Löw (*Fr.* 9, 463).

**IV. COPPER PEROXIDE.**—The oxide CuO<sub>2</sub> has not been obtained, but a hydrate CuO<sub>2</sub>.H<sub>2</sub>O is known. This hydrate is prepared (1) by digesting finely-divided CuO, or Cu(OH)<sub>2</sub>, with H<sub>2</sub>O<sub>2</sub>Aq for several days at 0° (Thénard; Krüss, *B.* 17, 2593); (2) by shaking very dilute CuSO<sub>4</sub>Aq with excess of MnO<sub>2</sub>.xH<sub>2</sub>O or PbO<sub>2</sub>, keeping cold (Schmid, *J. pr.* 98, 136); (3) by adding H<sub>2</sub>O<sub>2</sub>Aq to a solution of Cu-NH<sub>3</sub> sulphate (Weltzien, *A.* 140, 207). CuO<sub>2</sub>.H<sub>2</sub>O is very easily decomposed with evolution of O; decomposition of the moist hydrate in presence of water begins at 0° (Krüss, *l.c.*). When quickly washed with cold

water, pressed between paper, and then dried *in vacuo*, it is obtained pure. This hydrate forms an olive-green powder; it reacts with acids to give cupric salts and  $H_2O_2$ ; dilute  $HClAq$  is said to produce a little  $O$ .

**Oxides of copper other than  $Cu_2O$ ,  $Cu_2O$ ,  $CuO$ , and  $Cu_2O$ .** Different chemists have asserted the existence of oxides of the form  $xCu_2O.yCu_2O$  intermediate between  $CuO$  and  $Cu_2O$ , obtained either by strongly heating  $CuO$ , or by the action of hypochlorites on cupric salts in solution (v. Krüger, *P.* 62, 445; Crum, *A.* 55, 218; Frey, *A. Ch.* [3] 12, 457; Krüss, *B.* 17, 2593). But according to Osborne (*Am. S.* [3] 82, 833) these bodies are all mixtures of  $CuO$  and  $Cu_2O$ ; this result is confirmed by the experiments of Debray and Joannis on the dissociation of these mixtures (*C. R.* 99, 583), and by the thermal measurements made by Joannis (*C. R.* 100, 999).

**Copper, oxybromide of, v. COPPER, OXYHALOID COMPOUNDS OF.**

**Copper, oxychlorides of, v. COPPER, OXYHALOID COMPOUNDS OF.**

**Copper, oxyfluoride of, v. COPPER, OXYHALOID COMPOUNDS OF.**

**Copper, oxyhaloid compounds of.**—Several oxychlorides of the form  $Cu_xCl_yO_z$  are known; an oxyfluoride  $CuF_x.Cu(OH)_y$ , and an oxyiodide  $2CuI_2.CuO.4H_2O$ , are also known; an oxybromide probably exists, but it has not been isolated.

**COPPER OXYBROMIDE.**—When a little  $NH_4Aq$  is added to  $CuBr_2Aq$ , a pale-green pp. is obtained, which becomes grey on heating; both of these bodies are oxybromides according to Löwig (*P.* 14, 485).

**COPPER OXYCHLORIDES.**—Various compounds of  $CuO$  with  $CuCl_2$  are obtained by digesting  $CuCl_2$  with  $Cu(OH)_2$ , also by the incomplete ppn. of  $CuCl_2$  by alkalis, and also by the action of  $O$  on moist  $CuCl_2$ . The following are the chief oxychlorides:—

I.  $CuCl_2.2CuO.4H_2O$ ; blue-green pp. by adding to  $CuCl_2$  enough  $KOH$  to decompose  $\frac{2}{3}$  of the  $CuCl_2$ ; or by diluting  $CuCl_2Aq$  until the liquid is blue (Gladstone, *C. J.* 8, 211). This oxychloride loses  $3H_2O$  at  $140^\circ$ , leaving a chocolate-coloured monohydrate (Kane, *A. Ch.* 72, 277).

II.  $2(CuCl_2.3CuO).7H_2O$ ; green pp. by adding excess of  $NaCl.H_2O.Aq$  to boiling  $CuCl_2Aq$ , or by the action of  $NaClAq$  on  $Cu(C_2H_3O_2)_2$  (Casselmann, *Fr.* 4, 24). Also obtained by adding  $NH_4Aq$ , insufficient for complete decomposition, to a mixture of  $CuSO_4Aq$  with excess of  $NaCl$  (Reindel, *J. pr.* 106, 378).

III.  $CuCl_2.3CuO.4H_2O$ ; occurs native as *Atacamite*; used in the arts as *Brunswick green*. Prepared by the action of air on copper plates covered with  $HClAq$  or  $NH_4ClAq$ ; or by digesting in air a mixture of  $NaCl$ ,  $Cu$  turnings, and  $CuSO_4.5H_2O$  with enough water to form a thick magma, or by exposing moist  $CuCl_2$  to the air (Vogel, *D. P. J.* 136, 238; v. also Field, *P. M.* [4] 24, 128; Debray, *Bl.* [2] 7, 104).

**COPPER OXYFLUORIDE  $CuF_x.Cu(OH)_y$**  [ $= CuF.OH$ ] (Balbiano, *G.* 14, 74). A greenish-white solid obtained by adding to  $HFAq$ ,  $CuO$  or  $CuCO_3$  in quantity not sufficient to saturate the acid; or by mixing  $CuSO_4Aq$  and  $KFAq$ .

**COPPER OXYIODIDE  $2CuI_2.CuO.4H_2O$** ; prepared

by the action of  $Cu$  on  $BaI_2Aq$  in presence of air (v. *supra*, *CUPROUS COMDS.*).

**Copper, oxysulphides of,  $xCuS.yCuO$ .** When  $Na_2SAq$  is dropped into an ammoniacal solution of  $CuSO_4$ , at  $70^\circ-80^\circ$  till the blue colour disappears, a pp. of  $5CuS.CuO$  is formed; at higher temperatures the pp. contains more  $CuO$ , and at ordinary temperatures  $CuS$  is the product (Pelouze, *A. Ch.* [3] 17, 393). According to Maumené (*A. Ch.* [3] 18, 311) various oxysulphides are formed during the action of conc.  $H_2SO_4$  with  $Cu$ , but this is negated by the experiments of Pickering (*C. J.* [2] 18, 112).

**Copper, phosphides of.**—Two phosphides of copper are known,  $Cu_3P_2$  and  $Cu_2P_3$ ; another,  $Cu_4P_3$ , probably exists. The molecular weight of none of these compounds is known with certainty.  $Cu$  and  $P$  may be melted together in all proportions.

I. **TRI-COPPER PHOSPHIDE  $Cu_3P_2$ .** Obtained by passing  $PH_3$  over warm  $CuCl_2$ , or by passing  $PH_3$  into  $CuSO_4Aq$  (H. Rose, *P.* 14, 188; 24, 328). According to Böttger (*J.* 1857, 107) the pp. produced by boiling  $P$  with  $CuSO_4Aq$ , and washing with  $K_2Cr_2O_7Aq$  acidulated with  $H_2SO_4$  (to remove basic  $Cu$  phosphate), has the composition  $Cu_3P_2$ . Prepared by the reaction of  $PH_3$  with  $CuCl_2$ , the phosphide is, a black solid, insol.  $HClAq$ , and loses half its  $P$  when strongly heated in  $H$ . Prepared by passing  $PH_3$  into  $CuSO_4Aq$ , the phosphide is sol.  $HClAq$  with evolution of inflammable  $PH_3$ . Prepared by Böttger's method the phosphide is an easily oxidised powder, slowly dissolved by  $HClAq$  with evolution of non-inflammable  $PH_3$  (v. also Sidot, *C. R.* 84, 1454).

II. **HEXACOPPER PHOSPHIDE  $Cu_6P_3$ .** Obtained by leading  $PH_3$  over heated  $Cu_2Cl_2$  or  $Cu_2S$  (H. Rose, *P.* 6, 209; 24, 328); or by strongly heating  $Cu_3P_2$  in  $H$  (Rose, *l.c.*); by passing  $P$  vapour over  $Cu$  heated to dull redness (Abel, *C. J.* [2] 3, 249). Grey-black solid,  $\alpha$  sol.  $HNO_3Aq$ , insol.  $HClAq$ .

A **DI-COPPER PHOSPHIDE,  $Cu_2P_2$** , is described as a grey powder obtained by heating  $CuHPO_3$  in a stream of  $H$  (H. Rose, *P.* 14, 188; 24, 328). Also produced by heating  $P$  with  $Cu$  turnings, and then carefully heating the product with amorphous  $P$  (Berzelius; but cf. Abel, *C. J.* [2] 3, 249). A phosphide, having the composition  $Cu_2P_2$ , was obtained by Cross & Higgins (*C. J.* 35, 424) by heating  $Cu_2Cl_2Aq$  with amorphous  $P$  to  $160^\circ$  for many hours.

**Copper, salts of.** Compounds obtained by replacing  $H$  of acids by  $Cu$ . Copper forms two classes of salts, the *cuprous*  $Cu_2X_2$  [ $X = Cl, Br, I, SCN, SO_2, \&c.$ ], and the *cupric*  $CuX_2$  [ $X = Cl, NO_2, SO_2, CO_2, \&c.$ ]. Few cuprous salts except those

derived from haloid acids are known; a few double salts of this class have been prepared, e.g.  $Cu_2SO_3.(NH_4)_2SO_3$ , and some *cupro-cupric* salts are known, e.g.  $Cu_2SO_3.CuSO_3.5H_2O$ . The cuprous salts are generally insol. water, while the normal cupric salts as a class dissolve in water. The cuprous salts are less stable than the cupric; but cuprous iodide is so much more stable than cupric iodide, that the latter has not been isolated, reactions which might be expected to yield  $CuI_2$ .

(e.g.  $\text{KIAq} + \text{CuSO}_4\text{Aq}$ ) produce  $\text{Cu}_2\text{I}_2$  and iodine. Many basic cupric salts are known. The cuprous salts are not generally obtained by reacting on  $\text{Cu}_2\text{O}$  with acids, but by reduction of cupric salts (v. e.g. CUPROUS CHLORIDE). Cupric salts are usually obtained by reactions between acids and  $\text{CuO}$  or  $\text{CuCO}_3$ . A great many cupric salts have been prepared (v. CARBONATES, NITRATES, SULPHATES, &c.); the following are the chief salts of this class:—*bromate, carbonates, chlorate* (and salts of other chlorine oxyacids), *iodate and periodate, molybdates, nitrates and nitrites, phosphate* (and salts of other phosphorus oxyacids), *selenates and selenite, silicates, sulphates and sulphites, tungstates, uranates, vanadates*.

**Copper, selenides of.** I. CUPROUS SELENIDE  $\text{Cu}_2\text{Se}$ . A steel-grey mass, obtained by heating Cu turnings with Se. Occurs native as *Berzelianite*. II. CUPRIC SELENIDE  $\text{CuSe}$ . A greenish-black solid, obtained by passing Se vapour over copper plates (Little, A. 112, 211); S.G. 6.66. Also formed by passing  $\text{H}_2\text{Se}$  into a solution of a cupric salt (Berzelius).

**Copper, silicide of.** No definite compound has been isolated. Bodies more or less resembling alloys of Cu and Si are obtained by heating  $\text{K}_2\text{SiF}_6$  with Na and Cu (v. Deville a. Caron, C. R. 45, 163; Winkler, J. pr. 91, 193).

**Copper, silicofluoride of.**  $\text{CuSiF}_6 \cdot \text{CH}_3\text{O}$ . Blue crystals, obtained by dissolving  $\text{CuO}$  in  $\text{H}_2\text{SiF}_6\text{Aq}$ ; deliquescent; heated to  $60^\circ$  gives  $\text{CuSiF}_6 \cdot 4\text{H}_2\text{O}$  (Berzelius; Stolba, J. pr. 102, 7). Decomposed at  $130^\circ$ – $140^\circ$  giving  $\text{CuF} \cdot \text{OH}$ ,  $\text{SiF}_4$ , and  $\text{HF}$ ; absorbs  $\text{NH}_3$  giving  $\text{CuF} \cdot \text{OH} \cdot 2\text{NH}_3$ ,  $\text{NH}_4\text{F}$ , and  $\text{SiO}_2$  (Balbiano, G. 14, 74).

**Copper, sulphides of.** Two sulphides of copper are known,  $\text{Cu}_2\text{S}$  and  $\text{CuS}$ . As neither has been gasified the molecular formulæ are not known with certainty; Pickering (C. J. 39, 401) says that  $\text{CuS}$  heated in H at  $260^\circ$  gives  $\text{Cu}_2\text{S}$ , and at c.  $650^\circ$  it yields Cu; because of this reaction he thinks that the formula of cupric sulphide ought to be  $\text{Cu}_2\text{S}_2$  and not  $\text{CuS}$ . *Cuprous sulphide*,  $\text{Cu}_2\text{S}$ , is the more stable of the two sulphides; both are distinctly basic, forming the basic radicles of various sulpho-salts; but  $\text{CuS}$  also combines with  $\text{Na}_2\text{S}$  &c., forming compounds in which  $\text{CuS}$  acts as the negative radicle (v. CUPROUS, and CUPRIC, SULPHIDES; Combinations). Compounds are also known which probably contain the radicle  $\text{CuS}_2$  (v. p. 262).

I. CUPROUS SULPHIDE  $\text{Cu}_2\text{S}$ . Occurs native as *Copper-glance*; S.G. 5.97 (Karsten, S. 65, 320, 394). Crystallises in rhombic forms *a:b:c* = 582:1:973; and also in regular octahedra; isomorphous in both forms with  $\text{Ag}_2\text{S}$ . Forms compounds with some less positive sulphides (v. Combinations).

**Formation.**—1. By heating a mixture of 4 parts finely divided Cu with 1 part S (Winkelblech, A. 21, 34). Spirals of Cu burn in S vapour to  $\text{Cu}_2\text{S}$ .  $\text{Cu}_2\text{S}$  is also formed by repeatedly and strongly pressing together a mixture of Cu and S (Spring, B. 16, 999).—2. By the action of  $\text{NH}_4\text{SHAq}$  on Cu (Heumann, B. 6, 748).—3. By heating  $\text{CuSO}_4$  with carbon.

**Preparation.**—1. By heating electrolytically deposited copper with conc.  $\text{H}_2\text{SO}_4$  for a short time at c.  $124^\circ$  (Pickering, C. J. 39, 402).—2. By heating pure  $\text{CuS}$  in a stream of H to c.  $265^\circ$  so long as  $\text{H}_2\text{S}$  is evolved (P., l.c.).—3. By passing

$\text{H}_2\text{S}$  into solution of a Cu salt in presence of  $\text{NaHCO}_3$  at  $200^\circ$  (de Senarmont, A. Ch. [3] 32, 116).—4. By heating  $\text{CuSO}_4$ , or other Cu salt, in dry  $\text{H}_2\text{S}$  and then in H (Carnot, Bl. [2] 32, 163).

**Properties and Reactions.**—(S.G. v. supra.) Greyish-blue solid, fusible at moderate temperature.—1. Generally said to be unchanged when heated in *hydrogen*, but according to Pickering it is reduced to Cu by heating in H stream at c.  $650^\circ$  (C. J. 39, 404).—2. Reduced to Cu by heating to white heat in *water vapour* (Regnault, A. Ch. 62, 387).—3. Chlorine slowly acts on hot  $\text{Cu}_2\text{S}$ .—4. Heated in air gives  $\text{CuSO}_4$  and  $\text{CuO}$ .—5. Heated with *cupric oxide* forms  $\text{SO}_2$  and Cu or  $\text{Cu}_2\text{O}$ .—6. Heated with *litharge*,  $\text{SO}_2$ , a little  $\text{Cu}_2\text{O}$ ,  $\text{PbO}$ , and  $\text{Pb}$  are formed.—7. *Phosphoretted hydrogen* forms Cu phosphide.—8. *Alkali carbonate* does not react with  $\text{Cu}_2\text{S}$  when the two are heated together, but in presence of carbon or caustic alkali a part of the  $\text{Cu}_2\text{S}$  is reduced to Cu.—9. Heated with *nitre*,  $\text{K}_2\text{SO}_4$  and Cu are formed.—10. *Silver nitrate* reacts in accordance with the equation  $\text{Cu}_2\text{S} + 4\text{AgNO}_3 = 2\text{Cu}(\text{NO}_3)_2 + \text{Ag}_2\text{S} + 2\text{Ag}$  (Heumann, B. 6, 761; 8, 534; Schneider, P. 152, 471; 154, 295).—11. Boiling conc. *hydrochloric acid* slowly forms  $\text{Cu}_2\text{Cl}_2$ ; *cold nitric acid* forms  $\text{CuS}$  and  $\text{Cu}(\text{NO}_3)_2$ ; *hot nitric acid* forms  $\text{Cu}(\text{NO}_3)_2$  and separates S.—12. Heated in *carbon dioxide* to about  $250^\circ$ – $300^\circ$  Cu is formed (Pickering, C. J. 39, 405).

**Combinations.**—1. With *non-metallic sulphides* (i.)  $\text{Cu}_2\text{S} \cdot \text{P}_2\text{S}_5$ , and  $2\text{Cu}_2\text{S} \cdot \text{P}_2\text{S}_5$ ; produced, the former by adding  $\text{P}_2\text{S}_5$  to ammoniacal  $\text{Cu}_2\text{Cl}_2\text{Aq}$ , the latter by heating the first to redness in a retort (Berzelius, P. 7, 29). (ii.)  $2\text{Cu}_2\text{S} \cdot \text{P}_2\text{S}_5$ , the pp. from ammoniacal  $\text{Cu}_2\text{Cl}_2\text{Aq}$  by alkaline polysulphides is heated with  $\text{P}_2\text{S}_5$  (Berzelius). (iii.)  $3\text{Cu}_2\text{S} \cdot 2\text{As}_2\text{S}_3$ , occurs native as *Binnite*;  $3\text{Cu}_2\text{S} \cdot \text{As}_2\text{S}_3$ , occurs native as *Enargite*. (iv.)  $\text{Cu}_2\text{S} \cdot \text{Sb}_2\text{S}_3$ , occurs native as *Copper-antimony glance*;  $3\text{Cu}_2\text{S} \cdot \text{Sb}_2\text{S}_3$  is formed by heating  $2\text{Cu}_2\text{S} \cdot \text{CuS} \cdot \text{Sb}_2\text{S}_3$ , which is produced by precipitating  $\text{CuSO}_4\text{Aq}$  by  $\text{Na}_2\text{SbS}_4$ .—2. With *metallic sulphides*.  $\text{Cu}_2\text{S} \cdot \text{FeS}$ ,  $3\text{Cu}_2\text{S} \cdot \text{FeS}$ , and  $\text{Cu}_2\text{S} \cdot 2\text{FeS} \cdot \text{FeS}$ , occur as minerals.—3. With *non-metallic and metallic sulphides*. (i.)  $4(\text{Cu} \cdot \text{Fe})\text{S} \cdot \text{As}_2\text{S}_3 = \text{Tennantite}$ ;  $3\text{Cu}_2\text{S} \cdot 3\text{FeS} \cdot \text{As}_2\text{S}_3 = \text{Epigenite}$ . (ii.)  $\text{Cu}_2\text{S} \cdot 2\text{PbS} \cdot \text{Sb}_2\text{S}_3 = \text{Bourmonite}$ .

II. CUPRIC SULPHIDE  $\text{CuS}$  (or  $\text{Cu}_2\text{S}_2$ , v. beginning of COPPER, SULPHIDES or) occurs native as *Covellite*; S.G. 4.59 to 4.64 (Karsten, S. 65, 320, 394). A green-black solid; by compressing at 6500 atmos. appears as dark-blue metal-like mass (Spring, B. 16, 1142). Acts as a basic sulphide, forming compounds with less positive sulphides; but also forms compounds with  $\text{Na}_2\text{S}$  &c., in which  $\text{CuS}$  forms the negative part of the salt.

**Colloidal form of  $\text{CuS}$**  (Spring a. De Boeck, Bl. [2] 48, 165). An aqueous solution of  $\text{CuS}$  is obtained by ppg. a Cu salt solution by  $\text{H}_2\text{S}$ , or preferably by  $\text{NH}_4\text{HSAq}$ , and prolonged washing by decantation with dilute  $\text{H}_2\text{SO}_4\text{Aq}$ , then dissolving in water and boiling for a few moments to expel  $\text{H}_2\text{S}$ . The aqueous solution of  $\text{CuS}$  is dark-coloured, with slight greenish fluorescence; the  $\text{CuS}$  is ppg. by addition of various salts, e.g. alum,  $\text{Al}_2\text{SO}_4$ , &c.

**Formation.**—By adding an alkaline sulphide to solution of a Cu salt; Thomsen (B. 11, 2048) says that the pp. formed by adding  $\text{Na}_2\text{SAq}$  to

$\text{CuSO}_4\text{Aq}$  has the composition  $\text{Cu}_2\text{S}_4$ . By passing  $\text{H}_2\text{S}$  into solution of a Cu salt.

**Preparation.**—1.  $\text{CuSO}_4\text{Aq}$ , prepared from pure electrolytic Cu, is ppd. by  $\text{H}_2\text{S}$ , and the pp. is dried at a low temperature in a current of  $\text{H}_2\text{S}$ .—2. Pure electrolytic Cu is heated with conc.  $\text{H}_2\text{SO}_4$  to about  $180^\circ$  for some little time, the residue is washed, and heated for a short time in a rapid current of H at c.  $160^\circ$  (Pickering, *C. J.* 89, 401).—3. Pure finely-divided  $\text{Cu}_2\text{S}$  is treated with cold conc. nitric acid, the residue is thoroughly washed.—4.  $2\frac{1}{2}$  parts finely divided Cu (ppd. by Zn) are gently heated with 1 part flowers of S, so that the excess of S sublimed; any residual S may be removed by washing with KOHAq.

**Properties and Reactions.**—1. Moist  $\text{CuS}$  readily oxidises in air to  $\text{CuSO}_4$ .—2. Heated to c.  $330^\circ$  for some hours,  $\text{Cu}_2\text{S}$  is formed (Pickering, *C. J.* 89, 406).—3. Heated in carbon dioxide to c.  $180^\circ$   $\text{Cu}_2\text{S}$  is formed, and at c.  $350^\circ$  Cu is produced; heated in hydrogen to c.  $200^\circ$  reduction begins, and at c.  $265^\circ$   $\text{Cu}_2\text{S}$  is formed, and at c.  $620^\circ$  Cu is produced (Pickering, *C. J.* 39, 403).—4. Dissolved by nitric acid with separation of S; hot conc. hydrochloric acid slowly forms  $\text{Cu}_2\text{Cl}_2$ .—5. Dissolved by potassium cyanide solution, also by solution of alkali bicarbonates. 6. Insoluble in alkali sulphides.—7. Not attacked by  $\text{H}_2\text{SO}_4\text{Aq}$  containing  $\frac{1}{2}$  of its volume of  $\text{H}_2\text{SO}_4$  (Hofmann, *A.* 115, 286).

**Combinations.**—1. The following compounds of CuS with sulphide of arsenic and antimony are described by Berzelius, obtained by reactions between Cu salts and sulpharsenates and sulphantimonates (*P.* 7, 29):  $2\text{CuS}.\text{As}_2\text{S}_3$ ;  $12\text{CuS}.\text{As}_2\text{S}_3$ ;  $2\text{CuS}.\text{As}_2\text{S}_3$ ;  $3\text{CuS}.\text{Sb}_2\text{S}_3$ .—2. Berzelius also describes the compounds with phosphorus sulphides,  $\text{CuS.P}_2\text{S}_5$ ;  $2\text{CuS.P}_2\text{S}_5$ .—3. With sulphides of the alkali metals. Schneider (*P.* 138, 311) obtained  $\text{K}_2\text{S}.3\text{Cu}_2\text{S}.2\text{CuS}$  ( $=\text{K}_2\text{Cu}_2\text{S}_4$ ) by heating together 1 part finely-divided Cu, 6 parts  $\text{K}_2\text{CO}_3$ , and 6 parts S; when the same proportions of Cu,  $\text{Na}_2\text{CO}_3$ , and S were used, the compound  $\text{Na}_2\text{S}.3\text{Cu}_2\text{S}.2\text{CuS}$  ( $=\text{Na}_2\text{Cu}_2\text{S}_4$ ) was produced. Schneider also describes the compounds  $\text{K}_2\text{FeCu}_2\text{S}_4$  and  $\text{Na}_2\text{FeCu}_2\text{S}_4$ , obtained by heating Fe, S, and  $\text{K}_2\text{CO}_3$  or  $\text{Na}_2\text{CO}_3$ .

**III. COMPOUNDS OF HYPOTHETICAL COPPER TRISULPHIDE ( $\text{CuS}_3$ ).** When  $\text{CuSO}_4\text{Aq}$  to which excess of  $\text{NH}_3\text{Aq}$  has been added is dropped into  $(\text{NH}_4)_2\text{SAq}$  until a pp. forms, the liquid is filtered and allowed to stand in absence of air, a salt  $\text{Cu}_2(\text{NH}_4)_2\text{S}_3$  [ $?=(\text{NH}_4)_2\text{S}.2\text{CuS}_3$ ] is formed in red needles. This compound is decomposed on exposure to air, or by addition of warm water. A corresponding K salt was obtained by Priwoznik (*B.* 6, 1291) by the action of alkali polysulphides on  $\text{Cu}_2\text{O}$ ,  $\text{CuO}$ , or  $\text{Cu}_2\text{S}$ . (For more details v. Priwoznik, *l.c.*; Peltzer, *A.* 128, 184; Gescher, *A.* 141, 350; 143, 375; Bloxam, *C. J.* [2] 3, 94; Vohl, *J. pr.* 102, 82; Berzelius, *P.* 7, 29).

**Copper, telluride of.** By boiling a solution of Cu acetate in presence of ppd. Te, Parkman (*J.* 1861, 126) obtained  $\text{Cu}_2\text{Te}$  as a black powder. If the solution is cold and  $\text{SO}_2$  is added, the pp. is  $\text{CuTe}$ . M. M. P. M.

**COPPER-AMMONIUM COMPOUNDS. (Cuprammonium compounds. Cupramines).** Many of the bodies which are formed by the combination of  $\text{NH}_3$  with the haloid and other com-

pounds of Cu may be regarded as compounds of various hypothetical radicles supposed to be derived from  $\text{NH}_3$ ,  $\text{N}_2\text{H}_4$ ,  $\text{N}_3\text{H}_5$ , &c., by replacing  $\text{H}$ , by  $\text{Cu}$ , or  $\text{Cu}_2$ . Thus the compounds  $\text{CuCl}_2.2\text{NH}_3$  and  $\text{Cu}_2\text{Cl}_2.2\text{NH}_3$  may be formulated as  $\text{N}_2\text{H}_4(\text{Cu})\text{Cl}_2$  and  $\text{N}_2\text{H}_4(\text{Cu}_2)\text{Cl}_2$  respectively. From these compounds others may be derived by assuming that part of the H is substituted by  $\text{NH}_2$ ; thus the compound  $\text{CuCl}_2.4\text{NH}_3$  may be formulated as  $\text{N}_2\text{H}_4(\text{NH}_2)_2(\text{Cu})\text{Cl}_2$ . Compounds supposed to be derived from the hypothetical radicle  $\text{N}_2\text{H}_4(\text{Cu})$  are sometimes called *cupro-ammonium compounds*; examples of these are *cupro-ammonium chloride*  $\text{N}_2\text{H}_4(\text{Cu})\text{Cl}_2$ , *diammonium - cupro - ammonium iodide*  $\text{N}_2\text{H}_4(\text{NH}_2)_2(\text{Cu}_2)\text{I}_2$ . Compounds supposed to be derived from the hypothetical radicle  $\text{N}_2\text{H}_4(\text{Cu})$  are sometimes called *cupri-ammonium compounds*; examples of these are *cupri-ammonium chloride*  $\text{N}_2\text{H}_4(\text{Cu})\text{Cl}_2$ , *diammonium-cupri-ammonium oxide*  $\text{N}_2\text{H}_4(\text{NH}_2)_2(\text{Cu})\text{O}$ . It is, however, very doubtful whether anything is gained at present by this extremely hypothetical way of formulating the double compounds of  $\text{NH}_3$  and Cu salts. M. M. P. M.

**COPRINE.** A name given by Niemikowicz (*M.* 7, 241) to the methylo-hydroxide of DIRMETHYL-AMIDO-ACETONE (*q. v.*).

**COPTINE.** An alkaloid contained, together with berberine, in *Coptis trifolia* (Gross, *N. Rep. Pharm.* 23, 53; Schultz, *Ph.* [3] 14, 973; *J. Ph.* 14, 373).

**CORALLIN v. ROSOLIC ACID** and anhydride of TRI-OXY-DI-PHENYL-TOLYL-CARBONOL.

**CORIAMYRTIN**  $\text{C}_{20}\text{H}_{20}\text{O}_{10}$ . [ $220^\circ$ ]. S. 1:44 at  $22^\circ$ . S. (alcohol) 2 at  $22^\circ$ . [ $\alpha$ ] =  $24.5$  at  $20^\circ$ . The active principle of *Coriaria myrtifolia*, a purgative and poisonous plant growing in Southern Europe (Riban, *Bl.* 1864, 1, 87; 1867, 1, 79), formerly used for the production of a black dye. Prisms (from alcohol). Dextrorotatory HI forms a black pp. which gives an alcoholic solution, which is turned crimson by NaOH. Baryta forms  $\text{BaC}_{20}\text{H}_{20}\text{O}_{10}$  (?). Br gives  $\text{C}_{20}\text{H}_{20}\text{Br}_2\text{O}_{10}$ , which crystallises in needles (from alcohol).

*Hexa-acetyl derivative*  $\text{C}_{20}\text{H}_{20}\text{Ac}_6\text{O}_{16}$ , 3aq [below  $100^\circ$ ]. Transparent brittle mass.

**CORIANDEER OIL**  $\text{C}_{15}\text{H}_{22}\text{O}$ . [ $\alpha$ ]<sub>D</sub> =  $-92.55^\circ$  at  $15^\circ$ . The volatile oil of Coriander seeds (Trommsdorff, *Ar. Ph.* [2] 2, 114; Kavalier, *J. pr.* 58, 226). Decomposed by distillation forming  $\text{C}_{20}\text{H}_{22}\text{O}$  ( $165^\circ$ – $170^\circ$ ).  $\text{P}_2\text{O}_5$  forms a terpene  $\text{C}_{15}\text{H}_{24}$ . On treatment with iodine it gives cymene. It forms a solid sodium derivative  $\text{C}_{15}\text{H}_{21}\text{ONa}$  and various others. On oxidation with neutral  $\text{KMnO}_4$  it gives a ketone  $\text{C}_{15}\text{H}_{18}\text{O}$  ( $186^\circ$ ), S.G. .897, which combines with  $\text{NaHSO}_4$ , and is converted by further oxidation into  $\text{CO}_2$ , acetic acid, and dimethyl-succinic acid. Alkaline  $\text{KMnO}_4$  oxidises it to  $\text{CO}_2$ , acetic, and oxalic acids (Grosser, *B.* 14, 2485). HCl forms  $\text{C}_{15}\text{H}_{22}\text{Cl}$ , S.G. .953, while HI gives  $\text{C}_{15}\text{H}_{24}\text{I}$ , which explodes below  $100^\circ$ .

**CORIDINE**  $\text{C}_{10}\text{H}_7\text{N}$ . ( $211^\circ$ ). S.G. 21–974. A base of the pyridine series occurring in coal tar (Thienius, *C. C.* 1862, 53). Turns litmus paper blue. Sl. sol. water, v. sol. other ordinary menstrua. The hydrochloric acid solution gives a pp. with  $\text{HgCl}_2$ , which melts at  $28^\circ$ , but may be obtained as white needles. Colours acidified pine wood yellowish red.— $\text{B}^+\text{H}_2\text{PtCl}_6$ : orange pp. **CORK v. CELLULOSE**, vol. i. p. 721.

**CORNEIN** v. **PROTEIDS**, *Appendix C.***CORNICULARIC ACID**  $C_7H_{10}O_4$  or

$Ph.C(CO_2H).CH.CO.CH_2.Ph.$  [115°]. Long colourless needles or tables. Formed as a by-product in the reduction of pulvic acid to di-hydro-cornicularic acid. This latter acid is also formed by reduction of cornicularic acid with zinc-dust and NaOH (Spiegel, *B.* 15, 1516; *A.* 219, 23).

**Cornicular-lactone**  $C_7H_{10}O_4$  or

$OC- -O$

$Ph.C:CH.C:CH.Ph.$  [141°]. Yellow needles. Insol. in caustic alkalis even on boiling.

**Di-hydro-cornicularic acid**  $C_7H_{10}O_4$ , i.e.  $(C_6H_5)_2C_2H_4(OH).CO_2H$ . *Di-phenyl-oxy-angelic acid*. [184°]. Colourless needles. Sol. alcohol, ether, benzene, and acetic acid, sl. sol.  $CS_2$ , insol. ligroin. Prepared by reduction of pulvic acid with zinc-dust and  $NH_4$ ,  $CO_2$  being evolved. On further reduction with sodium amalgam it gives tetra-hydro-cornicularic acid. On fusion with KOH it is resolved into phenyl-succinic acid and toluene. Distillation with quick-lime gives  $C_6H_5.CH_2.CH_2.CO.CH_2.C_6H_5$ .  $Ac_2O$  forms a compound  $C_7H_8O_4.HOAc$  [99°].

**Salts.**— $A'Ag$  and  $A'Pb$ : amorphous white pps.

**Methyl ether**  $A'Me$ : colourless monoclinic prisms [68°], formed by reduction of pulvic ether or from silver dihydrocorniculate and EtI.

**Lactone**  $C_7H_{10}O_4$ . [117°]. Colourless needles. Sol. ether, benzene, acetic acid, hot alcohol, and  $CS_2$ , slightly in ligroin. Prepared by heating the acid (Spiegel, *B.* 14, 1690).

**Tetra-hydro-cornicularic acid**  $C_7H_{12}O_4$  or  $C_6H_5.CH_2.CH(OH).CH.CH(C_6H_5).CO_2H$  (?). *Di-phenyl-oxy-valeric acid*. Thick colourless oil. Formed by reduction of di-hydro-cornicularic acid with sodium amalgam (Spiegel, *B.* 14, 1692).

**Lactone**  $C_7H_{12}O_4$ . [71°]. Flat colourless needles. Sol. alcohol, ether, and benzene, sl. sol. ligroin, insol. water. Formed by boiling the acid with water (Spiegel, *B.* 14, 1692).

**Iso-Di-hydro-cornicular-lactone**  $C_7H_{12}O_4$ . [c. 105°]. Colourless needles. Formed as a by-product in the reduction of pulvic acid (Spiegel, *B.* 15, 1546).

**CORNIN**. A crystalline bitter substance which may be extracted by water from the root of *Cornus florida* (Geiger, *A.* 14, 206). Ppd. by lead subacetate.

**CORTICIC ACID**  $C_{12}H_{18}O_6$ ? An amorphous acid said to exist in cork (Siewert, *Z.* 1868, 383).

**CORYDALINE**  $C_{10}H_{11}NO_3$ . [130°]. Occurs in the roots of *Corydalis bulbosa*, *C. fabacea*, and *Aristolochia cava* (Wackenroder, *Kastn. Arch.* (1826); Peschier, *Trommsd. N. J.* 17, 80; Winckler, *Pharm. Centr.* 1832, 38; *A.* 87, 225; Ruickholdt, *A.* 64, 369; Müller, *Vierteljahr. pr. Pharm.* 8, 526; Wicke, *A.* 137, 274). The alkaloid is extracted by dilute acid, and may be isolated after ppp. by sodium phosphotungstate. Short prisms (from strong solutions) or slender needles (from dilute solutions); insol. water, sol. ordinary solvents. Tastes bitter. Ppd. by NaOH from its solution in acids, the pp. being sol. excess. Ppd. by the usual reagents for alkaloids.— $B'HCl$  5aq: tufts of needles.— $B'H.PtCl_4$ : yellow crystalline pp.— $B'H_2SO_4$ : needles, sl. sol. water.

**Ethyl-iodide**  $B'EtI$ . Crystalline, sl. sol.

water. Not decomposed by aqueous NaOH, but converted by moist  $Ag_2O$  into an alkaline hydroxide.—( $B'EtCl$ ),  $PtCl_4$ : amorphous pp.

**COTARNAMIC ACID** v. **NARCOTINE**.**COTARNIC ACID** v. **NARCOTINE**.**COTARNINE** v. **NARCOTINE**.

**COTO BARK**. Two kinds of coto bark are exported from Bolivia, one from the interior of the country called cinchona-coto or genuine coto, derived probably from some plant belonging to the Lauraceae or Terebinthaceae, rather than to the Rubiaceae. It is used in cases of diarrhoea and colic, as also for neuralgia, rheumatism and gout. The other kind of coto-bark or paracoto-bark (Jobst a. Hesse), from the banks of the river Mapiro, resembles the former in appearance, though its physiological action is much weaker. True coto bark contains cotoin and dicotoin; the other bark contains paracotoin, hydrocotoin, and its dibenzoyl derivative, leucotin, and oxy-leucotin; piperonylic acid is present in both (Harz, *Ar. Ph.* [3] 7, 214; Gietl, *ibid.* 221; Wittstein, *ibid.* 219; Burkart, *Med. Corres. Artz. Verein Württemberg*, 1876; Bälz, *Centralblatt Med. Wiss.* 1878; Jobst a. Hesse, *A.* 199, 17). The physiological action of cotoin and paracotoin has been studied by Albertoni (*J.* 1883, 1353, 1488).

**Cotoin**  $C_{20}H_{24}O_6$ . [130°].

**Preparation.**—The finely-powdered coto-bark is exhausted with ether, the extract evaporated to one-tenth, and the residue mixed with warm petroleum; on cooling a black resinous mass separates, the liquid from which on evaporation deposits crystals of cotoin. From the resin the compound is also obtained by boiling with lime, and the solution acidified with acetic acid; from this liquid cotoin is deposited in leaflets or pale golden needles. It is finally purified by charcoal.

**Properties.**—Prisms or tabular crystals, v. sol. alcohol, chloroform, and benzene, sl. sol. water and petroleum; sol. alkalis and their carbonates, but reprecipitated on acidification. Neutral to litmus. Inactive.

**Reactions.**—1. With *nitric acid* it gives a blood-red colouration. —2. *Reduces* gold and silver salts and Fehling's solution when warmed. —3. With *ammonia* and  $Pb(OAc)_2$  it gives a yellow flocculent pp.  $C_2H_5I$ ,  $PbO$ . —4. Heated with concentrated acids or alkalis it yields benzoic acid.

**Triacetyl derivative**  $C_{22}H_{24}Ac_3O_6$ . [94°]. Prisms, sol.  $CHCl_3$  and water.

**Tri-bromo-cotoin**. [114°]. Yellow prisms, insol. cold water, decomposed by hot water, sol. alcohol, chloroform, and ether.

**Dicotoin**  $C_{20}H_{24}O_{11}$ . **Anhydride of cotoin?** [74°–77°]. When crude cotoin is treated with boiling water, crystals of cotoin at first separate, then leaflets of dicotoin, which are separated by a sieve. Pale yellow glistening leaflets, sol. alcohol, acetone, ether, and alkalis. By potash it is converted into cotoin; and by  $Ac_2O$  into tri-acetyl-cotoin (Jobst a. Hesse, *A.* 199, 29).

**Paracotoin**  $C_{20}H_{24}O_6$ . [152°].

**Preparation.**—Finely divided para-coto bark is extracted with ether, and from the residue left on evaporation a crystalline mass of paracotoin, oxy-leucotin, leucotin, and its di-benzoyl derivative separates out. This is fractionally

crystallised from alcohol, when the paracotoin separates out first.

**Properties.**—Pale yellow leaflets, sol. ether and chloroform; of neutral reaction; does not react with  $\text{Ac}_2\text{O}$ .

**Reactions.**—1. Sol. nitric acid forming a yellow nitro-product.—2. Br gives an unstable bromo-derivative.—3. On fusion with potash it yields formic and protocatechuic acids, but when boiled with a solution of potash paracumarhydrin is formed thus  $\text{C}_{10}\text{H}_{12}\text{O}_4 + 2\text{H}_2\text{O} = 2\text{C}_8\text{H}_8\text{O}_4 + \text{CO}_2$ , together with paracotoic acid.

**Hydrocotoin**  $\text{C}_{15}\text{H}_{14}\text{O}_4$ . [98°]. Occurs in para-coto bark. Extracted by dilute soda from the resinous mass obtained after separation of the paracotoin, leucotin, and oxyleucotin. Large pale yellow prisms, sol. hot water and alcohol, v. sol. chloroform and acetone. With ferric chloride and sulphuric acid it gives a dark-brown colouration; with bromine it gives a bromo-derivative  $\text{C}_{15}\text{H}_{13}\text{BrO}_4$ , crystallising in monoclinic prisms [147°], sol. ether, chloroform, and alcohol. Further bromination gives a di-bromo-derivative,  $\text{C}_{15}\text{H}_{11}\text{Br}_2\text{O}_4$ , crystallising in prisms [95°]. On fusion with potash it yields hydrocotone and benzoic acid (Jobst a. Hesse, A. 199, 57).

**Acetyl derivative**  $\text{C}_{15}\text{H}_{13}\text{O}_5(\text{OAc})$ . [83°]. White prisms. V. sol. hot water. Forms a bromo-derivative  $\text{C}_{15}\text{H}_{11}\text{BrAcO}_4$ , [166°], crystallising in white prisms, sol. chloroform and boiling alcohol.

**Hydrocotone**  $\text{C}_{15}\text{H}_{14}\text{O}_4$ . [49°]. (243°). V.D. 11.16. Formed by fusion of leucotin with potash; white prisms, sol. ether, acetone, and chloroform. Heated with concentrated nitric acid it yields di-nitro-cotone  $\text{C}_{15}\text{H}_{10}(\text{NO}_2)_2\text{O}_4$ , which crystallises in brown leaflets of metallic lustre; when heated it explodes, emitting violet vapours.

**Di-benzoyl-derivative**  $\text{C}_{18}\text{H}_{22}\text{Bz}_2\text{O}_4$ . [113°]. Occurs in the para-coto bark; white prisms, sol. alcohol, ether, and acetone, sl. sol. hot water. Concentrated nitric acid forms with it a bluish-green resin. Sulphuric acid gives a dark-yellow colouration. On fusion with potash it yields hydrocotone and benzoic acid. It is unaltered by acetic anhydride. With bromine it yields a di-bromo-derivative  $\text{C}_{18}\text{H}_{20}\text{Br}_2\text{O}_4$ , [147°], crystallising in white prisms, sol. alcohol and acetone, as well as a tetra-bromo-derivative  $\text{C}_{18}\text{H}_{18}\text{Br}_4\text{O}_4$ , [84°], crystallising in octahedra, sol. alcohol and chloroform.

**Paracumarhydrin**  $\text{C}_8\text{H}_8\text{O}_4$ . [83°]. Formed by boiling paracotoin with aqueous KOH. Laminæ; smelling like coumarin; sl. sol. cold water, v. e. sol. alcohol.

**Leucotin**  $\text{C}_{10}\text{H}_{10}\text{O}_4$ . [97°]. The chief constituent of the extract of para-coto bark. Separates from the alcoholic mother-liquor in the preparation of para-cotoin. Small prisms. Sl. sol. boiling water, v. sol. alcohol and ether. Inactive. Not attacked by  $\text{Ac}_2\text{O}$ .  $\text{HNO}_3$  gives a bluish-green resin and solution. Potash-fusion gives benzoic, formic, and protocatechuic acids, protocatechuic aldehyde, cotogenin, and hydrocotoin. Br gives a di-bromo-derivative  $\text{C}_{10}\text{H}_8\text{Br}_2\text{O}_4$ , [187°], and a tri-bromo-derivative  $\text{C}_{10}\text{H}_6\text{Br}_3\text{O}_4$ , [167°].

**Cotogenin**  $\text{C}_8\text{H}_8\text{O}_4$ . [210°]. Obtained by fusing leucotin with KOH. May be crystallised

from HOAc. Gives off pyrocatechin when strongly heated. V. sl. sol. cold alcohol and ether. Dissolves in alkalis, forming solutions which turn brown in the air.  $\text{FeCl}_3$  colours its alcoholic solution green.

**Paracotoic acid**  $\text{C}_{15}\text{H}_{14}\text{O}_5$ . [108°]. Formed by boiling paracotoin with dilute alkalis  $\text{C}_{15}\text{H}_{12}\text{O}_5 + \text{H}_2\text{O} = \text{C}_{15}\text{H}_{14}\text{O}_5$ . Yellow amorphous powder, sol. alcohol and ether, insol. water. The Ba, Pb, and Ca salts ( $\text{MA}'_2$ ) are yellow amorphous pps.

**Oxyleucotin**  $\text{C}_{15}\text{H}_{12}\text{O}_{12}$ . [184°]. Occurs in paracoto bark. Prisms (from alcohol). V. e. sol. alcohol and HOAc, m. sol. ether. By heating with conc.  $\text{HNO}_3$  it is converted into a bluish-green resin and a bluish-green solution. Inactive. It is not coloured by  $\text{FeCl}_3$ . Conc. HCl at 140° gives protocatechuic acid. Potash-fusion gives protocatechuic acid and aldehyde, benzoic acid, formic acid, and cotogenin. Br gives a di-bromo-derivative  $\text{C}_{15}\text{H}_{10}\text{Br}_2\text{O}_{12}$ , [192°], and a tetra-bromo-derivative  $\text{C}_{15}\text{H}_8\text{Br}_4\text{O}_{12}$ , [159°].

**PARACOTO OIL.** Prepared from the para-coto bark by distillation with superheated steam. Light mobile liquid. S.G.  $^{15}_4$  .93,  $\alpha_D = -2.12$ ; separated by fractional distillation into (a) and (b) paracotene, (a), (b) and (γ) paracotole.

(a) Paracotene  $\text{C}_{15}\text{H}_{14}$ . V.D. 5.17. (160°). S.G.  $^{15}_4$  .87.  $[\alpha]_D = +9.34$ . Strongly refractive oil of aromatic odour.

(b) Paracotene  $\text{C}_{15}\text{H}_{14}$ . (171°). V.D. 4.83. S.G.  $^{15}_4$  .88.  $[\alpha]_D = -6.3$ . Oil of faint aromatic odour.

(γ) Paracotole  $\text{C}_{15}\text{H}_{12}\text{O}$ . (221°). V.D. 6.17. S.G.  $^{15}_4$  .93.  $[\alpha]_D = -11.87$ , isomeric with the oil of cubeb, which it resembles in many respects.

(b) Paracotole  $\text{C}_{15}\text{H}_{10}\text{O}_2$ . (236°). V.D. 12.8. S.G.  $^{15}_4$  .95.  $[\alpha]_D = -5.93$ . Oil of faint aromatic odour.

(γ) Paracotole  $\text{C}_{15}\text{H}_{10}\text{O}_2$ . (243°). S.G.  $^{15}_4$  .97.  $[\alpha]_D = -5.2$ . Turns yellow on exposure from absorption of oxygen (Jobst a. Hesse, A. 199, 75).

**COTTON v. CELLULOSE.**

**COUMALIC ACID**  $\text{C}_9\text{H}_8\text{O}_4$ , i.e.

$\text{O}-\text{CH}=\text{C}(\text{CO}_2\text{H})$

. Coumalic acid. [207°]

$\text{OC}-\text{CH}=\text{CH}$

Prepared by heating malic acid with  $\text{H}_2\text{SO}_4$  or  $\text{ZnCl}_2$ , and precipitating the melt in water; the yield is nearly theoretical. The reaction probably consists in the splitting off of formic acid with production of the semi-aldehyde of malonic acid  $\text{CH}_2 < \begin{smallmatrix} \text{CHO} \\ \text{CO}_2\text{H} \end{smallmatrix}$ , which then undergoes further condensation, forming coumalic acid (Pechmann, B. 17, 936). Sublimable. Small colourless prisms. V. sol. alcohol and acetic acid, sl. sol. cold, more sol. hot, water. It reduces ammoniacal silver and copper solutions on boiling. Its aqueous solution is decomposed on boiling. On oxidation it gives fumaric acid.  $\text{NH}_3$  forms, in the cold, oxy-pyridine carboxylic acid.

**Methyl ether** 'A' Me: [74°]; (c. 260°), long, colourless needles or plates.

**Coumal-anilidic acid**

$\text{CO}_2\text{H}.\text{CH}:\text{CH}.\text{C}(\text{CO}_2\text{H})\text{CH.NHPh. (?)}$

**Mono-methyl ether**

$\text{CO}_2\text{H}.\text{CH}:\text{CH}.\text{C}(\text{CO}_2\text{Me})\text{CH.NHPh. [140°].}$

## COUMARIC ACID

Formed by the action of aniline on an alcoholic solution of the methyl-ether of coumalic acid (Pechmann & Welsh, *B. 17*, 2392; *J. 47*, 145). Yellow needles, v. sol. hot alcohol, chloroform, and benzene, sl. sol. ether, insol. water. By boiling with aqueous NaOH it is converted into the phenyl derivative of oxy-nicotinic acid— $C_6H_5N(OPh)CO_2H$  (1:2:5).

Bromocoumalic acid v. vol. i. p. 565.

PARACOUMARHYDRIN v. COTO BARK.

**o-COUMARIC ACID**  $C_9H_8O_3$ . *o*-Oxy-cinnamic acid. *o*-Oxy-phenyl-acrylic acid. Mol. w. 184. [208°]. V.D. 6.5 (calc. 6.66).

**Occurrence.**—In melilot (*Melilotus officinalis*) and in the leaves of *Angracum fragrans* (Zwenger, *A. Suppl.* 8, 30).

**Formation.**—From *o*-amido-cinnamic acid by the diazo-reaction (Fischer, *B. 14*, 479; *A. 221*, 274).

**Preparation.**—Coumarin (10 g.) is added to a solution of sodium (3.5 g.) in dry alcohol (65 c.c.), and the mixture heated for 1½ hours. The product is diluted and evaporated to a small bulk. The coumaric acid is ppt. by HCl. The ppt. is dissolved in  $Na_2CO_3$  aq., freed from unaltered coumarin by shaking with ether, the acid is reprecip. by HCl and crystallised from water (Ebert, *A. 226*, 347; cf. Delalande, *A. Ch.* [3] 6, 343; *A. 45*, 333; Bleibtreu, *A. 59*, 183).

**Properties.**—Long needles, v. sl. sol. cold water and ether, v. sol. alcohol, insol.  $CHCl_3$  and  $CS_2$ . Not volatile with steam. Decomposed on distillation with formation of phenol. Its solution in alkalis is yellow with green fluorescence. Conc. HBr aq slowly changes it in the cold into its anhydride, coumarin.

**Reactions.**—1. *Potash-fusion* gives acetic and *o*-oxy-benzoic acids.—2. *Sodium amalgam* gives *o*-oxy-phenyl-propionic acid (Tiemann & Herzfeld, *B. 10*, 286).—3. *Bromine* (1 mol.) added to its solution in  $CS_2$  gives a white crystalline substance [ $\alpha$ . 111°] (? di-bromo-*o*-oxy-phenyl-propionic acid), which, when exposed to the air, gives off HBr, and yields ( $\beta$ )-di-bromo-coumarin [177°].

**Salts.**— $BaA'$ , aq.: nodules, v. sol. water.— $PbA'$ : crystalline ppt.— $ZnA'$ : needles, sl. sol. cold water.— $AgA'$ .

**Constitution.**—Like cinnamic, fumaric, and citraconic acids, coumaric acid is a symmetrical derivative of ethylene, so that it might be expected to exist in two modifications. These two modifications are found in its alkyl derivatives. The existence of two modifications might also be accounted for by ascribing to one of them the

formula  $C_6H_5 \begin{array}{c} CH:CH \\ \diagup \quad \diagdown \\ O \quad C(OH)_2 \end{array}$  (Anschütz, *A. 239*, 161; 240, 183). Except as regards boiling-point, the physical properties of the ( $\alpha$ )-coumaric ethers stand to those of their ( $\beta$ )-isomerides exactly as those of citraconic and maleic ethers stand to those of mesaconic and fumaric ethers respectively (Perkin, *C. J.* 39, 559).

( $\alpha$ )-(or *Allo*-) **Methyl derivative**  $C_6H_5(OMe)CH:CH.CO_2H$ . [ $\alpha$ . 89°]. Formed by heating coumarin with NaOH (2 mols.) and MeI (1 mol.) at 150° (Perkin, *C. J.* 39, 403). Monoclinic crystals (from  $CS_2$ ).  $\alpha:b:c = 677:1:123$ ;  $\beta = 87^\circ 12'$ . V. e. sol. alcohol, m. sol. ligroin. Changes into the ( $\beta$ )-isomeride on boiling, or

even by exposing a concentrated alcoholic solution to sunlight. Sodium amalgam reduces it, as well as its ( $\beta$ )-isomeride, to the methyl derivative of oxy-phenyl-propionic acid. Br in  $CS_2$  gives the methyl ether of ( $\alpha$ )-di-bromo-*o*-oxy-( $\beta$ )-phenyl-propionic acid (v. vol. i. p. 603). Undiluted bromine forms the methyl-ether of tri-bromo-oxy-phenyl-propionic acid. HNO<sub>3</sub> gives the same di-nitro-derivative as with its ( $\beta$ )-isomeride. Fuming HI unites in the cold, and on adding  $Na_2CO_3$  there is formed  $C_6H_5(OMe)CH:CH_2$ .  $KMnO_4$  oxidises it to [2:1]  $C_6H_5(OMe)CO_2H$ .— $BaA'$ .—Methyl ether [2:1]  $C_6H_5(OMe)CH:CH.CO_2Me$ . (276°). S.G.  $\frac{1}{4}$  1.140;  $\frac{3}{4}$  1.278. Formed by heating coumarin, MeOH, and MeI for 8 hours at 100°. Converted by  $NH_3$  at 150° into the amide of the ( $\beta$ )-isomeride.

( $\beta$ )-**Methyl derivative**

[2:1]  $C_6H_5(OMe)CH:CH.CO_2H$ . [183°]. Formed by heating [2:1]  $C_6H_5(OMe)CHO$  (2 pts.) with NaOAc (1 pt.) and Ac<sub>2</sub>O (3 pts.) at 175° (Perkin, *C. J.* 31, 414). Formed also by heating its ( $\alpha$ )-isomeride. Small monoclinic prisms (from xylene)  $\alpha:b:c = 441:1:807$ ;  $\beta = 64^\circ 41'$ . M. sol. alcohol. Br in  $CS_2$  gives the methyl derivative of ( $\beta$ )-di-bromo-oxy-phenyl-propionic acid (v. vol. i. p. 603). Undiluted bromine forms the methyl ether of tri-bromo-oxy-phenyl-propionic acid.  $KMnO_4$  gives  $C_6H_5(OMe)CO_2H$  (Tiemann & Will, *B. 15*, 2078). *Potash-fusion* gives salicylic acid. HNO<sub>3</sub> forms a di-nitro-derivative [193°].—Methyl ether  $C_6H_5(OMe)CH:CH.CO_2Me$ . [293°]. S.G.  $\frac{1}{4}$  1.1486;  $\frac{3}{4}$  1.1362. V.D. 6.5 (calc. 6.6). M.M. 2.389.  $\mu_D$  1.5905 at 10°. Obtained by means of  $PCl_5$  and  $HOMe$ . Formed also by heating its ( $\alpha$ )-isomeride. With Br in  $CS_2$  it gives  $C_6H_5(OMe)CHBrCHBr.CO_2Me$  [58°] and an isomeride [125°].

**Amide**  $C_6H_5(OMe)CH:CH.CONH_2$ . [192°]. Small needles (from alcohol).

( $\alpha$ )-(or *Allo*-) **Ethyl derivative**

[2:1]  $C_6H_5(OEt)CH:CH.CO_2H$ . [102°] (F. a. E.); [104°] (P.). From alcohol, sodium (3.2 g.), coumarin (10 g.) and EtI (12 g.) (Fittig & Ebert, *A. 216*, 142; Perkin, *C. J.* 39, 412). White plates (from water), or tables (from dilute alcohol). V. sl. sol. cold water, sl. sol. hot water, v. sol. alcohol and ether. Sparingly volatile with steam. **Reactions.**—1. On distillation an oil is got, whence  $Na_2CO_3$  extracts the ( $\beta$ )-isomeride; the yield is 30 p.c.—2.  $KMnO_4$  gives ethyl-salicylic aldehyde and acid.—3. Sodium amalgam forms the ethyl derivative of oxy-phenyl-propionic acid.—4. Br forms a dibromide [155°]. **Salts.**—( $C_6H_5O_2$ ),  $Ba$  2aq.— $CaA'$ , 2aq. S. 2:11 at 21°.

**Ethyl ether**  $C_6H_5(OEt)CH:CH.CO_2Et$ . (291°). S.G.  $\frac{1}{4}$  1.084;  $\frac{3}{4}$  1.074.  $\mu_D = 1.558$ . From coumarin (14 g.), NaOH (8 g.) and water, by evaporating to a small bulk and heating the residue with alcohol and EtI (32 g.) at 100°.

( $\beta$ )-**Ethyl derivative**

$C_6H_5(OEt)CH:CH.CO_2H$ . [133°] (E. a. F.); [155°] (P.). Formed, together with the ( $\alpha$ )-isomeride by treating *o*-coumaric acid with NaOEt and EtI. Formed also from the ( $\alpha$ )-isomeride by distillation, or by long heating to a high temperature (Fittig & Ebert, *A. 216*, 144). Obtained by heating  $C_6H_5(OEt)CHO$  with NaOAc and acetic anhydride at 160° (Perkin, *C. J.* 39, 418). Needle (from water), or prisms (from alcohol). V. sl.

sol. cold water, sl. sol. hot water. V. e. sol. alcohol or ether. The Na salt is oxidised by  $\text{KMnO}_4$  to ethyl-salicylic aldehyde and ethyl-salicylic acid. Sodium amalgam forms the ethyl derivative of oxy-phenyl propionic acid. Br forms a dibromide [155°]. Salts.— $(\text{C}_9\text{H}_7\text{O}_2)_2\text{Ca}$  2aq. S. 48 at 21°.— $\text{BaA}'$  4aq. Ethyl ether  $\text{C}_9\text{H}_7(\text{OEt})\text{CH}:\text{CH}:\text{CO}_2\text{Et}$ . (303°). S.G. 1.09. Formed by treating the preceding with  $\text{PCl}_5$ , followed by alcohol. Formed also by boiling the (a)-isomeride for some time.

#### Acetyl derivative

$\text{C}_9\text{H}_7(\text{OAc})\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [146°]. Formed by gently heating salicylic aldehyde (3 pts.) with  $\text{NaOAc}$  (4 pts.) and  $\text{Ac}_2\text{O}$  (5 pts.) (Tiemann a. Herzfeld, B. 10, 284). Needles (from water). V. sol. hot water, alcohol, and ether. Converted by dilute  $\text{KOH}$  aq into coumaric acid; and by heating above 150° into  $\text{HOAc}$  and coumarin.

#### Carboxy-methyl derivative

$\text{CO}_2\text{H}.\text{CH}_2.\text{O}.\text{C}_6\text{H}_4.\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . *o*-Coumar-oxy-acetic acid. [196°]. Formed by heating *o*-aldehyde-phenoxy-acetic acid (1 pt.) with acetic anhydride (5 pts.) and sodium acetate (3 pts.) to boiling for 1 or 2 hours (Rossing, B. 17, 2997). Yellow needles. V. sol. alcohol, ether, and hot water, sl. sol. benzene, chloroform, and cold water. Sublimable.

Di-bromide  $\text{C}_9\text{H}_4\text{Br}_2\text{CHBr}:\text{CHBr}:\text{CO}_2\text{H}$ . [220°]. White needles; sl. sol. benzene, chloroform, and water, v. sol. alcohol and ether.

Anhydride  $\text{C}_9\text{H}_4\text{CH}:\text{CH}:\text{CO} > \text{O}$ . [176°]. Crystalline solid. V. sol. alcohol and ether, sl. sol. water. Formed by heating the acid with phosphoric acid.

Di-bromide  $\text{C}_9\text{H}_4\text{Br}_2\text{CHBr}:\text{CHBr}:\text{CO}$ . [c. 213°].

Orange-yellow needles; v. sol. alcohol and ether, sl. sol. water and benzene (Rossing, B. 17, 3001).

Bromo-coumaric acid v. vol. i. p. 564.

#### *m*-Coumaric acid

$(3:1)\text{C}_9\text{H}_7(\text{OH})\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [191°]. Formed by heating *m*-oxy-benzaldehyde with acetic anhydride and sodium acetate; or by boiling diazocinnamic acid with water (Tiemann a. Ludwig, B. 15, 2048). White prisms. Sol. alcohol, ether, benzene, and hot water.

#### Acetyl derivative

$\text{C}_9\text{H}_7(\text{OAc})\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [151°]. White needles, sol. alcohol, ether, and hot water.

#### Methyl derivative

$\text{C}_9\text{H}_7(\text{OMe})\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [115°]. Long white needles, sol. alcohol, ether, and benzene, sl. sol. hot water (Tiemann a. Ludwig, B. 15, 2048).

Carboxy-methyl derivative  $\text{C}_{11}\text{H}_{10}\text{O}_3$ , i.e.  $\text{C}_6\text{H}_4(\text{O}.\text{CH}_2.\text{CO}_2\text{H})\text{CH}:\text{CH}:\text{CO}_2\text{H}$  [13]. *m*-Phenoxy-acetic-acrylic acid. *m*-Coumaroxy-acetic acid. Phenyl-glycolic-*m*-acrylic acid. [219°]. Prepared by heating *m*-aldehyde-phenoxy-acetic acid with sodium acetate and acetic anhydride. White needles (from hot water). V. sol. alcohol, ether, and acetic acid, sl. sol. cold water. The Ag, Pb, Cu, and Fe salts are sparingly soluble pps. (Elkan, B. 19, 8047).

*p*-Coumaric acid  $\text{C}_9\text{H}_7(\text{OH})\text{CH}:\text{CH}:\text{CO}_2\text{H}$ .

*p*-Oxy-cinnamic acid. *p*-Oxy-phenyl-acrylic acid. Naringenic acid. [206°].

Preparation.—1. 2½ kilos. of aloes are boiled

for two hours with 5 litres of water and 400 g. conc.  $\text{H}_2\text{SO}_4$ ; after cooling the liquor is decanted and the residue again boiled with 2 litres of water, the combined extracts are evaporated to ½, and when cold extracted with ether. The crude *p*-coumaric acid (yield: 1.5 to 1.8 p.c.) left on evaporating the ether is purified by conversion into the barium salt (Hlasiwetz, A. 136, 31; Eigel, B. 20, 2527).—2. *p*-Oxy-benzaldehyde (5 pts.) is heated at 175° with dehydrated sodium acetate (8 pts.) and acetic anhydride (10 pts.); the yield is 70 p.c. of the oxy-benzaldehyde (Tiemann a. Herzfeld, B. 16, 63, 283; Eigel). 3. By heating *p*-diazo-cinnamic acid with water; small yield (Gabriel, B. 15, 2301).—4. Together with phloroglucin by boiling naringenin with conc. aqueous  $\text{NaOH}$  (Will, B. 20, 299).

Properties.—Thick warts (anhy.) or long needles (with aq). V. sl. sol. cold water, v. sol. hot water, v. e. sol. alcohol and ether, sl. sol. benzene, insol. ligroin.  $\text{FeCl}_3$  colours the alcoholic solution brown. Sodium-amalgam gives *p*-oxy-phenyl-propionic acid. Potash-fusion forms *p*-oxy-benzoic acid (Barth, B. 12, 1259).

Salts.— $\text{NH}_4\text{A}'$  aq: monoclinic tables.— $\text{CdA}'$  3aq.— $\text{CuA}'$  6aq.— $\text{AgA}'$ .

#### Methyl derivative

$\text{C}_9\text{H}_7(\text{OMe})\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [169°] (E.); [171°] (P.). Formed by heating anisic aldehyde with acetic anhydride and sodium acetate at 180° (yield: 70 p.c. of the anisic aldehyde), or by saponification with  $\text{KOH}$  of the di-methyl-ether  $\text{C}_9\text{H}_7(\text{OMe})_2\text{CH}:\text{CH}:\text{CO}_2\text{Me}$  formed by heating the acid with methyl iodide and  $\text{KOH}$ . Occurs among the products of the action of  $\text{KOH}$  and  $\text{MeI}$  upon tyrosine (Körner a. Menozzi, G. 11, 549). Formed also by oxidising the methyl derivative of methyl oxy-styryl ketone with  $\text{NaOCl}$  (Einhorn a. Grabfeld, A. 243, 363). Yellow needles, m. sol. alcohol, hot water, and  $\text{HOAc}$ ; sl. sol. cold water and chloroform (Perkin). Gives when heated the methyl derivative of vinyl-phenol  $\text{CH}_2:\text{CH}:\text{C}_6\text{H}_4\text{OMe}$ . This body is also formed by successive treatment with  $\text{HI}$  and  $\text{Na}_2\text{CO}_3$  (Perkin, C. J. 83, 214).— $\text{A}'\text{Na}$ .— $\text{AgA}'$  (Eigel, B. 20, 2527).

Methyl ether  $\text{C}_9\text{H}_7(\text{OMe})\text{CH}:\text{CH}:\text{CO}_2\text{Me}$ . [89°]. (303°). Laminæ. In chloroform solution it takes up bromine, with production of  $\text{C}_9\text{H}_7(\text{OMe})\text{CHBr}:\text{CHBr}:\text{CO}_2\text{Me}$  [118°] (Valentini, G. 16, 424; Perkin, C. J. 39, 489).

Chloride  $\text{C}_9\text{H}_7(\text{OMe})\text{CH}:\text{CH}:\text{COCl}$ . [50°].

Amide  $\text{C}_9\text{H}_7(\text{OMe})\text{CH}:\text{CH}:\text{CONH}_2$ . [186°].

#### Acetyl derivative

$\text{C}_9\text{H}_7(\text{OAc})\text{CH}:\text{CH}:\text{CO}_2\text{H}$ . [c. 195°]. Formed by heating sodium *p*-oxy-benzoic aldehyde  $\text{C}_6\text{H}_4(\text{ONa})\text{CHO}$  with  $\text{NaOAc}$  and  $\text{Ac}_2\text{O}$  (Tiemann a. Herzfeld, B. 16, 65). Felted groups of slender needles (from hot water). Sublimes readily. Sol. boiling water, alcohol, ether, and  $\text{HOAc}$ , v. sl. sol. cold water, benzene, and  $\text{CHCl}_3$ .

Carboxy-methyl derivative  $\text{C}_{11}\text{H}_{10}\text{O}_3$ , i.e.  $\text{C}_6\text{H}_4(\text{O}.\text{CH}_2.\text{CO}_2\text{H})\text{CH}:\text{CH}:\text{CO}_2\text{H}$  [14]. *p*-Coumaroxy-acetic acid. Phenyl-glycolic-*p*-acrylic acid. [225°]. Prepared by boiling a mixture of *p*-aldehyde-phenoxy-acetic acid (1 pt.), sodium acetate (1 pt.), and acetic anhydride (8 pts.) for 5 hours. Warty crystals. Sol. benzene and benzoline, v. sol. alcohol, ether, and acetic acid, sl. sol. cold water. The Ag, Pb, Cu, and Fe salts are sparingly soluble pps. (Elkan, B. 19, 8048).

**Di-bromide of coumaric acid v. Di-bromo-oxy-phenyl-propionic acid.**

**Hydro-coumaric acid v. Oxy-phenyl-propionic acid.**

Other derivatives are described as Nitro-coumaric acid, Di-oxy-cinnamic acid, and Oxy-amido-cinnamic acid.

#### o-Coumaric aldehyde

$C_6H_5(OH)CH:CH.CO.H$ . *Oxy-cinnamic aldehyde*. [133°]. Long slender needles. V. sol. alcohol and ether, sl. sol. water.  $FeCl_3$  gives a red pp. Formed by the decomposition of its glucoside under the influence of emulsin (Tiemann & Kees, B. 18, 1962).

**Glucoside**  $[2:1]C_6H_5(OC_6H_5O_2).C_6H_5.CO.H$ . *Glucocoumaric aldehyde*. [199°]. Formed by adding a few drops of dilute NaOH to a mixture of helicin  $[2:1]C_6H_5(OC_6H_5O_2).CO.H$  and acetic aldehyde. This condensation even takes place in dilute aqueous solution and at a low temperature (Tiemann & Kees, B. 18, 1958). Fine white needles (containing aq). V. sol. hot water and alcohol, insol. ether and chloroform. Lævorotatory. By emulsin it is split up into coumaric aldehyde and glucose. Sodium amalgam reduces it to glucocoumaryl alcohol

#### Phenyl hydrazide of the glucoside

$C_6H_5(OC_6H_5O_2).C_6H_5.CH:N_2HPh$ : [132°]; sol. alcohol and hot water, nearly insol. cold water.

#### Oxim of the glucoside

$C_6H_5(OC_6H_5O_2).C_6H_5.CH:NOH$ : [230°]; long white needles (containing 2aq); v. sol. hot water, less sol. alcohol, insol. ether.

#### m-Coumaric aldehyde

$[3:1]C_6H_5(OH)CH:CH.CO.H$ . [100°]. From m-aldehyde-phenoxy-acetic acid, aldehyde, and dilute NaOHAq (Elkau, Z. 19, 3048).

#### p-Coumaric aldehyde

$[4:1]C_6H_5(OH)CH:CH.CO.H$ . [182°]. From p-aldehyde-phenoxy-acetic acid in the same way.

#### COUMARILIC ACID $C_6H_5O_2$ i.e.

$C_6H_5(OH).C:C.CO_2H$  or  $C_6H_5\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle.C.CO_2H$ . *o-Oxy-phenyl-propionic acid*. [191°] (F); [193°] (P.). (c. 312°). Formed by treating (a)-bromo-coumarin with hot alcoholic KOH (Perkin, C. J. 24, 45; Fittig, A. 216, 162). Long needles (from water); v. e. sol. alcohol, m. sol. water, sl. sol. chloroform and  $CS_2$ . Not attacked by Br or conc. HBr. Potash-fusion gives salicylic and acetic acids.  $KMnO_4$  forms only  $CO_2$ . Sodium amalgam reduces it to hydrocoumarilic acid  $C_6H_5O_2$ .

Salts.— $AgA'$ .— $CaA'$ , 3aq.— $BaA'$ , 4aq.

*Ethyl ether*  $EtA'$ : [27°]; (274° at 720 mm.) (Hantzsch, B. 19, 2401).

**Methyl derivative**  $C_6H_5(QMe).C:C.CO_2H$ . [126°]. From the methyl-derivative of *exo*-bromo-coumaric acid and dilute KOH (Perkin, C. J. 39, 423). Needles (from  $CS_2$ ).

#### Bromo-coumarilic acid

$C_6H_5Br\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle.C.CO_2H$ . [250°]. From (a)-di-bromo-coumarin and alcoholic KOH (Perkin, C. J. 24, 45). Needles, sl. sol. water, v. sol. alcohol.

#### Methyl derivative

$C_6H_5Br(OMe).CH.CO_2H$ . [168°]. Prepared from  $C_6H_5Br(OMe).C_6H_5Br.CO_2H$  and aqueous KOH

(Perkin, C. J. 39, 419). Small needles (from benzene).

#### p-Oxy-coumarilic acid Methyl derivative

$C_6H_5(OMe)\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle.C.CO_2H$  [4:2:1]. [196°]. Formed by boiling bromo-umbelliferon-methyl ether  $C_6H_5(OMe)\langle\begin{smallmatrix} CH:CBR \\ O.CO \end{smallmatrix}\rangle$  with conc. alcoholic KOH.

Long white needles. V. sol. alcohol and ether, scarcely sol. cold water, more readily in hot. Slightly volatile with steam.— $BaA'$ , 4aq: white crystalline solid (Will a. Beck, B. 19, 1783).

#### Ethyl derivative $C_6H_5O_2$ i.e.

$C_6H_5(OEt)\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle.C.CO_2H$  [4:2:1]. [163°]. Formed by boiling bromo-umbelliferon-ethyl ether  $C_6H_5(OEt)\langle\begin{smallmatrix} CH:CBR \\ O.CO \end{smallmatrix}\rangle$  with conc. alcoholic

KOH. Long felted needles (Will a. Beck, B. 19, 1785).

#### Hydro-coumarilic acid $C_6H_5O_2$ i.e.

$C_6H_5\langle\begin{smallmatrix} CH_2 \\ O \end{smallmatrix}\rangle.CH.CO_2H$ . [117°]. (299°).

Formed by treating coumarilic acid with sodium amalgam, and extracted by ether from the acidified product (Fittig, A. 216, 160). Pearly plates (from water); very volatile with steam. V. sol. alcohol and ether, m. sol. water. Partially decomposed on distillation, yielding a phenol. Gives phenol on distillation with lime.

Salts.— $AgA'$ .— $CaA'$ , 2aq.— $BaA'$ , 2aq.

*Ethyl ether*  $EtA'$ : [23°]. (273°).

#### p-Oxy-hydrocoumarilic acid Methyl deriva-

*tive*  $C_6H_5O_2$  i.e.  $C_6H_5(OMe)\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle.CH.CO_2H$

[4:2:1]. [114°]. Formed by reduction of the methyl derivative of oxy-coumarilic acid

$C_6H_5(OMe)\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle.C.CO_2H$  with sodium-amalgam. Hard prisms. V. sol. ordinary solvents. Volatile with steam (Will a. Beck, B. 19, 1783).

#### Ethyl derivative $C_6H_5O_2$ i.e.

$C_6H_5(OEt)\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle.CH.CO_2H$  [4:2:1]. [119°].

Formed by reduction of ethoxy-coumarilic acid  $C_6H_5(OEt)\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle.C.CO_2H$  with sodium amalgam. Hard white needles (Will a. Beck, B. 19, 1785).

#### Di-oxy-coumarilic acid Di-ethyl deriva-

*tive*  $C_6H_5(OEt)_2\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle.C.CO_2H$ . [195°]. From bromo-resculetic ether  $C_6H_5(OEt)_2\langle\begin{smallmatrix} O \\ C.HBr \end{smallmatrix}\rangle.CO$  and alcoholic KOH (Will, B. 16, 2119). Slender needles.

V. also METHYL-COUMARILIC ACID.

**COUMARIN**  $C_6H_5O_2$  i.e.  $C_6H_5\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle\langle\begin{smallmatrix} CH \\ O \end{smallmatrix}\rangle.CO$  Mol

w. 146. [67°]. (290°).

**Occurrence.**—In Tonka beans, the fruit of *Coumaruna odorata*, or *Dipteryx odorata*, as small white crystals between the seed coating and the kernel; found in woodruff (*Asperula odorata*), in *Melilotus officinalis* (as *melilotat*  $C_{14}H_{10}O_2$  [128°]), in the flowers of sweet-scented vernal grass (*Anthoxanthum odoratum*), in the leaves of Faham (*Angracum fragrans*), of an

other orchid, *Orchis fusca*, and of *Liatris odoratissima* (Guibourt, *Histoire des Drogues Simples*; Boullay a. Boutron-Chaillard, *J. Ph.* 9, 490; Delalande, *A. Ch.* [3] 6, 343; Bleibtren, *A. 59*, 177; Procter, *Rep. chim. App.* 1861, 143; Fontana, *B. J.* 14, 811; Guillemette, *A. 14*, 328; Rossmann, *A. 52*, 387; Gobbey, *A. 76*, 354).

**Formation.**—1. By boiling salicylic aldehyde with  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  (Perkin, *C. J.* 21, 53, 181; cf. vol. i. p. 158).—2. Together with  $\text{HOAc}$  by heating acetyl-coumaric acid (Tiemann a. Herzfeld, *B.* 10, 287).—3. By the action of  $\text{Br}$  at  $170^\circ$  on the anhydride of *o*-oxy-phenyl-propionic acid (Hochstetter, *A.* 226, 860).—4. By heating phenol with malic acid and  $\text{H}_2\text{SO}_4$  or  $\text{ZnCl}_2$ . The reaction probably takes place in the following stages: (1) By splitting off formic acid the semi-aldehyde of malonic acid is formed.

(2) By condensation of this aldehyde with the phenol an oxy-phenyl-lactic acid is produced—

(3) By splitting two mols. of water from this body a coumarin is formed:

(Fechmann, *B.* 17, 929).

**Properties.**—Triclinic crystals, *a:b:c* = .8833:1:3696 (Scacchi, *G.* 14, 568). Peculiar odour. M. sol. hot water, v. e. sol. alcohol, insol. cold aqueous baryta, but dissolves on boiling. Ether will not extract it from the solution, but acids, even  $\text{CO}_2$ , re-precipitate it. It appears, however, to have formed the barium salt of an oxy-acid, which is not *o*-coumaric acid, unless the boiling is prolonged after the coumarin is dissolved (Ebert, *A.* 216, 189). Coumarin dissolves in boiling aqueous  $\text{K}_2\text{CO}_3$  without evolution of  $\text{CO}_2$ , apparently forming a compound with it.  $\text{BaCO}_3$  has no action on coumarin.

**Reactions.**—1. Boiling conc. aqueous  $\text{KOH}$  gives *o*-coumaric acid.—2. Potash-fusion forms acetic and salicylic acids.—3. Gaseous  $\text{HBr}$  passed into its solution forms large transparent crystals [c.  $45^\circ$ ] of what is probably an addition-product. Exposed to the air, these crystals quickly lose  $\text{HBr}$ , leaving pure coumarin (Ebert, *A.* 226, 847).—4. Sodium amalgam reduces it to oxy-phenyl-propionic acid. In alcoholic solution sodium amalgam forms di-hydro-di-coumaric acid  $\text{C}_{12}\text{H}_{10}\text{O}_6$ , which is sl. sol. cold water, forms the salts  $\text{NaA}''$ ,  $\text{CaA}''$ ,  $\text{PbA}''$ ,  $\text{CuA}''$ ,  $\text{AgA}''$ , and an anhydride  $\text{C}_{12}\text{H}_8\text{O}_6$  [222°] (Zwenger, *A. Suppl.* 8, 32).

**Combinations with bases.**— $\text{C}_9\text{H}_6\text{O}_2\text{KOH}$ .— $\text{C}_9\text{H}_6\text{O}_2\text{NaOH}$ . Obtained by boiling coumarin (1 mol.) with aqueous  $\text{NaOH}$  (2 mols.) for a few minutes. Deliquescent; at  $160^\circ$  it becomes  $\text{C}_9\text{H}_5\text{O}_2\text{Na}_2\text{O}$ .— $\text{C}_9\text{H}_5\text{O}_2\text{Ba(OH)}$ .— $\text{C}_9\text{H}_5\text{O}_2\text{PbO}$ .— $\text{C}_9\text{H}_5\text{O}_2\text{AgO}$ : yellow pp. Formed by adding  $\text{AgNO}_3$  to the yellow solution of coumarin in

aqueous  $\text{KOH}$  (Perkin, *O. J.* 22, 192; Williams, *O. J.* 28, 850).

Formed by the action of hydroxylamine upon thiocoumarin in alcoholic solution. Long white needles. V. sol. alcohol, ether, and benzene; sol. hot water, nearly insol. cold. It is very stable to alkalis and acids, but by long heating with  $\text{HCl}$  it is split up into coumarin and  $\text{H}_2\text{NOH}$ .

Formed by ethylation of the oxim. Colourless plates. V. sol. alcohol, ether, and benzene, insol. water.

#### Phenyl-hydrazide

$\text{C}_6\text{H}_5\text{C}(\text{C}_6\text{H}_5)\text{C}(\text{N}_2\text{Ph}) : [144^\circ]$ . Formed by heating thiocoumarin with phenyl-hydrazine in alcoholic solution. Long yellow needles. V. sol. benzene and ether, sol. hot alcohol, sl. sol. cold alcohol, insol. water. Dissolves in  $\text{H}_2\text{SO}_4$  with a green colour (Tiemann, *B.* 19, 1662).

**Coumarin bromide**  $\text{C}_9\text{H}_6\text{OBr}_2$ , [105°]. From coumarin (7 pts.) and  $\text{Br}$  (8 pts.) in  $\text{CS}_2$  (Perkin, *C. J.* 17, 368; 9, 37). Oblique prisms (from alcohol); v. sol. alcohol, but decomposed by boiling therewith. Gives off  $\text{Br}$  a little above its melting-point. Alcoholic  $\text{KOH}$  converts it into (a)-bromo-coumarin (v. vol. i. p. 564).

**Chloro-coumarin** v. p. 57.

**Di-coumarin**  $\text{C}_{18}\text{H}_{10}\text{O}_4$ , i.e.

$\text{C}_6\text{H}_5\text{C}(\text{CH})\text{C}(\text{CH})\text{C}(\text{CO}_2\text{O})\text{C}_6\text{H}_5$  ? [above  $330^\circ$ ]. From salicylic aldehyde, sodium succinate, and  $\text{Ac}_2\text{O}$  at  $100^\circ$  (Dyson, *C. J.* 51, 62). Insol. ether, alcohol, and benzene, sl. sol. chloroform, and  $\text{HOAc}$ . Slowly dissolved in boiling  $\text{NaOH}$  aq., but is reprecipitated by acids. Reduced in alkaline solution by sodium amalgam to hydro-di-coumaric acid  $\text{C}_{12}\text{H}_{10}\text{O}_6$ , which is insol. water, sol.  $\text{CHCl}_3$  and benzene. It forms the salts  $\text{BaA}'$ ,  $\text{CaA}'$ , and  $\text{AgA}'$ . At  $133^\circ$  hydrodicoumaric acid splits up into water and its anhydride hydrodicoumarin  $\text{C}_{12}\text{H}_{10}\text{O}_4$  [256°]. It is reconverted into the acid by long heating with conc.  $\text{NaOH}$  aq. or with  $\text{HOAc}$ . Bromine acting on hydrodicoumarin in  $\text{CHCl}_3$  forms  $\text{C}_{12}\text{H}_{11}\text{BrO}_4$ .

Hydro-dicoumaric acid is perhaps

Reduced in aqueous alkaline solution by sodium amalgam it gives the dihydro-dicoumaric acid  $\text{C}_{12}\text{H}_{12}\text{O}_6$  or

not identical with Zwenger's acid. Its salts are  $\text{CaA}'$ ,  $\text{CaA}'$ ,  $\text{AgA}'$ . It forms an anhydride  $\text{C}_{12}\text{H}_{10}\text{O}_6$  [224°].

**Homologues of coumarin.** Obtained by the action of fatty anhydrides upon sodium *o*-oxybenzoic aldehyde (Perkin, *C. J.* 88, 10). They are described as anhydrides of the corresponding oxy-acids.

**Oxy-coumarins.** Described as *anhydrides of di-oxy-cinnamic acid*, &c. The di-oxy-benzenes and their homologues may be converted by treatment with malic acid and  $\text{H}_2\text{SO}_4$  into oxy-coumarins, and by aceto-acetic ether and a dehydrating agent into oxy-methyl-coumarins. When excess of aceto-acetic ether is used, small

quantities of polycoumarins are also formed (Pechmann, *B.* 17, 929, 2191; 20, 1328).

Thus from resorcin may be prepared umbelliferon  $[4\frac{1}{2}]$   $C_6H_4(OH)_2$   $\begin{matrix} CH:CH \\ | \\ O \cdot CO \end{matrix}$  [224°],

( $\beta$ )-methyl-umbelliferon  $[4\frac{1}{2}]$   $C_6H_4(OH)_2$   $\begin{matrix} CMe:CH \\ | \\ O \cdot CO \end{matrix}$  [248°],

and di-methyl-di-coumarin  $\begin{matrix} CH:CH \\ | \\ CO \cdot O \end{matrix}$   $C_6H_2(CMe)_4$   $\begin{matrix} CMe:CH \\ | \\ O \cdot CO \end{matrix}$ .  
Orcin gives rise to

$C_6H_2Me(OH)_2$   $\begin{matrix} CH:CH \\ | \\ O \cdot CO \end{matrix}$  [248°] and

$C_6H_2Me(OH)_2$   $\begin{matrix} CMe:CH \\ | \\ O \cdot CO \end{matrix}$  [250°].

Pyrogallol forms daphnetin

$[4\frac{3}{2}]$   $C_6H_3(OH)_3$   $\begin{matrix} CH:CH \\ | \\ O \cdot CO \end{matrix}$  [255°], and

( $\beta$ )-methyl-daphnetin  $[4\frac{3}{2}]$   $C_6H_3(OH)_3$   $\begin{matrix} CMe:CH \\ | \\ O \cdot CO \end{matrix}$ .

Phloroglucin gives

$C_6H_3(OH)_3$   $\begin{matrix} CMe:CH \\ | \\ O \cdot CO \end{matrix}$  [284°], and

'tri-methyl-tri-coumarin'

$C_6 \left\{ \begin{matrix} CMe:CH \\ | \\ O \cdot CO \end{matrix} \right\}_3$ .

Imido-dihydro-coumarin  $C_6H_4$   $\begin{matrix} NH \\ | \\ CH:CH \\ | \\ O \cdot CO \end{matrix}$   $\begin{matrix} NBz \\ | \\ CH:CH \\ | \\ O \cdot CO \end{matrix}$  [171°].

Benzoyl derivative  $C_6H_4$   $\begin{matrix} CH:CH \\ | \\ O \cdot CO \end{matrix}$  [171°].

Fine white needles; sol. warm ether, alcohol, benzene and acetic acid; insol. water. Formed by boiling an acetic acid solution of the benzoyl derivative of *o*-oxy-phenyl- $\alpha$ -imido-propionic anhydride  $\{C_6H_4(OH).C_6H_4(NBz).CO\}_2O$ . By treatment with concentrated aqueous NaOH it is converted into *o*-oxy-phenyl-glycidic acid

$C_6H_4(OH).CH.OH.CO_2H$

(Plöchl a. Wolfrum, *B.* 18, 1184; cf. Rebuffat, *G.* 15, 527).

Coumarin oxide  $C_6H_4$   $\begin{matrix} O \\ | \\ CH:CH \\ | \\ O \cdot CO \end{matrix}$

Inner anhydride of *o*-oxy-phenyl-glycidic acid. [158°]. Long needles or prisms. V. sol. ether and warm alcohol. Formed by boiling *o*-oxy-phenyl-glycidic acid with dilute  $H_2SO_4$ . By boiling with water it is partly converted back

again into oxy-phenyl-glycidic acid (Plöchl a. Wolfrum, *B.* 18, 1187).

#### COUMARIN-CARBOXYLIC ACID

$C_6H_4$   $\begin{matrix} O-CO \\ | \\ CH:C.COOH \end{matrix}$  [187°].

Formed by heating salicylic aldehyde, malonic acid, and glacial HOAc at 100° (Stuart, *C. J.* 49, 366). White needles (from water). It is not decomposed by boiling with water or on melting, but on heating above 190° it evolves  $CO_2$ , leaving coumarin.

Salts.—BaA' and AgA' are white pps.

COUMARIN DIHYDRIDE *v.* Anhydride of OXY-PHENYL-PROPIONIC ACID.

COUMARONE  $C_9H_6O$  i.e.  $C_6H_4$   $\begin{matrix} CH \\ | \\ O \end{matrix}$   $\begin{matrix} CH \\ | \\ O \end{matrix}$ .

(169°). Formed by heating coumarilic acid with lime,  $CO_2$  being split off (Fittig a. Ebert, *A.* 216, 168; 226, 847). Formed also by boiling *o*-aldehyde-phenoxy-acetic acid with  $Ac_2O$  and NaOAc (Rössing, *B.* 17, 3000). Heavy oil; volatile with steam. Not attacked by sodium amalgam. Converted by a drop of  $H_2SO_4$  into a reddish-white amorphous mass.

Dibromide  $C_9H_4OBr_2$  [86°]. Prisms (from  $CS_2$ ). Converted by boiling with water into coumarone and other products.

Bromo-coumarone  $C_9H_4BrO$  [86°]. From coumarone dibromide and alcoholic KOH. Needles (from dilute alcohol). V. e. sol. alcohol and ether, insol. water and alkalis.

*p*-Methoxy-coumarone  $C_9H_6O$  i.e.

$C_6H_4(OMe)$   $\begin{matrix} CH \\ | \\ O \end{matrix}$   $\begin{matrix} CH \\ | \\ O \end{matrix}$  [4:2:1]. (179°). Formed by dry-distillation of the silver salt of methoxy-coumarilic acid  $C_6H_4(OMe)$   $\begin{matrix} CH \\ | \\ O \end{matrix}$   $\begin{matrix} C.CO_2H \\ | \\ O \end{matrix}$  in a stream of  $CO_2$ . Colourless oil, having a strong odour of flowers. Somewhat heavier than water. Very volatile with steam (Will a. Beck, *B.* 19, 1784).

Oxy-methyl-coumarone  $C_9H_6O_2$  i.e.

$[4\frac{1}{2}]$   $C_6H_3(OH)$   $\begin{matrix} CMe \\ | \\ O \end{matrix}$   $\begin{matrix} CH \\ | \\ O \end{matrix}$  [97°]. Formed, by loss of  $CO_2$ , by distillation of oxy-methyl-coumarilic acid  $C_6H_3(OH)$   $\begin{matrix} CMe \\ | \\ O \end{matrix}$   $\begin{matrix} C.CO_2H \\ | \\ O \end{matrix}$ . White needles. Sol. benzene and hot water, v. e. sol. alcohol and ether. Dissolves in alkalis without alteration. Sparingly volatile with steam. Sublimes slowly at the ordinary temperature. Gives a violet colouration on warming with conc.  $H_2SO_4$  (Hantzsch, *B.* 19, 2929).

Coumarone- $\alpha$ -carboxylic acids are identical with COUMARILIC ACIDS (*q. v.*).

*o*-COUMARYL-ALCOHOL. Glucoside.

$C_6H_4(OC_6H_4O_2).C_6H_4.CH_2OH$ . Gluco-coumaryl alcohol. [115°]. Fine white needles (containing aq). V. sol. alcohol, insol. ether. Formed by reduction of gluco-*o*-coumaric aldehyde with sodium amalgam. By emulsion it is split up into coumaryl alcohol (which is an oil) and glucose (Tiemann a. Kees, *B.* 18, 1962).

CREATINE  $C_4H_7N_3O_2$  i.e.

$NH_2.C(NH).NMe.CH_2.CO_2H$ . Mol. w. 181. Methyl-guanido-acetic acid. S.G. 1.85. S. 1:8 at 18° S. (alcohol) 0.16.

Occurrence.—In the muscular flesh of mammalia, birds, amphibia, and fishes (Chevreul,

*J. Ph.* 21, 284; Pettenkofer, *A.* 52, 97; Liebig, *A.* 62, 282; 108, 354; Heintz, *P.* 62, 602; 70, 460; 78, 596; 74, 125; *C. R.* 24, 500; Gregory, *C. J.* 1, 25; Dessaignes, *C. R.* 88, 839; 41, 1258; *J. Ph.* [3] 32, 41; *A.* 97, 339; Schlossberger, *A.* 49, 344; 66, 80; Price, *C. J.* 3, 229; Städeler, *J. pr.* 72, 256). Occurs also in urine, blood, and brains (Verdeil a. Marcet, *J. Ph.* [3] 20, 89; Müller, *A.* 103, 142; Voit, *J.* 1867, 791). In some cases where creatine has been found it may have been formed from pre-existent creatinin by the process of extraction. Creatinin does not, however, appear to exist in flesh (Neubauer, *Fr.* 2, 22; Nawrocki, *Fr.* 4, 330).

**Synthesis.**—By the direct union of cyanamide with methyl-amido-acetic acid (sarcosine) in aqueous or alcoholic solution (Volhard, *Z.* [2] 5, 319; Strecker, *J.* 1868, 686).

**Preparation.**—Finely-chopped meat (250 g.) is heated with water (250 c.c.) at 60° for 10 minutes, the liquid is squeezed out and heated till the albumen is coagulated. The filtrate is treated with lead sub-acetate as long as ppn. occurs, is filtered, and freed from excess of lead by  $H_2S$ . The filtrate from  $PbS$  is evaporated to a syrup, from which creatine slowly separates; a further quantity may be ppd. by adding alcohol (2 or 3 vols.) (Neubauer, *Fr.* 2, 22; Mulder a. Monthaan, *Z.* [2] 5, 341).

**Properties.**—Monoclinic prisms (containing aq). Sl. sol. water, v. sl. sol. alcohol, insol. ether. The aqueous solution is neutral to litmus. Converted into its anhydride creatinin by heating with aqueous  $HCl$ , with  $ZnCl_2$ , with  $H_2SO_4$ , or even (although slowly) with water at 100°. Gaseous  $HCl$  passed over creatine at 100° also forms creatinin hydrochloride. If 5 or 6 drops of a 20 p.c. solution of  $AgNO_3$  are added to 2 c.c. of a cold saturated solution of creatine, and a solution of  $KOH$  is added so as just to redissolve the white pp. which is first formed, the liquid presently solidifies to a transparent jelly; reduction of silver takes place on heating (Engel, *C. R.* 78, 1707).

**Reactions.**—1. Boiling baryta-water splits it up into urea (or  $CO_2$  and  $NH_3$ ) and methyl-amido-acetic acid. Methyl-hydantoin is also formed.—2. Nitrous acid decomposes it, giving off half its nitrogen in the free state.—3. Alkaline  $NaOBr$  gives off two-thirds of the nitrogen as such (Hüfner, *J. pr.* [2] 1, 7).—4. Boiling with water and  $HgO$  gives methyl-guanidine and oxalic acid.—5. When heated with soda-lime it gives off methylamine.

**Salts.**— $B^+H_2SO_4$ : slender prisms.— $B^+HCl$ .— $B^+HNO_3$ : short thick prisms.— $B^+CdCl_2$ , 2aq: large crystals.— $B^+ZnCl_2$ : small crystals, resolved by hot water into creatine and  $ZnCl_2$  (Neubauer, *A.* 137, 298).— $HgC_2H_4N_2O_2$ , 3aq: white pp. from creatine,  $HgCl_2$ , and  $KOH$  (Engel, *C. R.* 80, 885; *B.* 8, 546).

**Amphicreatine**  $C_4H_8N_4O_2$ . A base occurring in muscular tissue (Gautier, *Bz.* [2] 48, 19). Yellow crystals; not ppd. by  $Cu(OAc)_2$ , or  $HgCl_2$ , but ppd. by sodium phosphomolybdate. Its hydrochloride is crystalline but not deliquescent. Its platinochloride forms soluble tables.

Isomeride of creatine v. **ALACREATINE**, vol. i. p. 93.

# CREATININE $C_4H_7N_5O_2$ i.e.

S. (alcohol) 1 at 16° (Liebig); 3 at 16° (Johnson).

**Occurrence.**—In human urine to the extent of 5 p.c. (Pettenkofer, *A.* 52, 97; Heintz, *P.* 62, 602; 73, 595; 74, 125; Liebig, *A.* 62, 298, 324; Neubauer, *A.* 119, 39). Occurs also in urine of horses, calves, and dogs (Heintz; Voit, *C. C.* 1867, 504; Socoloff, *A.* 78, 243; 80, 114; Maly, *A.* 159, 279) and in the flesh of some fish (Krukenberg, *J. Th.* 1881, 344).

**Formation.**—From creatine by the action of mineral acids or of dehydrating agents.

**Preparation.**—1. Fresh human urine is neutralised with milk of lime; chloride of calcium added as long as a pp. of phosphate of calcium continues to form; the filtrate evaporated till the salts crystallise out; 32 pts. of the mother-liquor mixed with 1 pt. of chloride of zinc dissolved in the smallest possible quantity of water; the mixture set aside for four days; and the zinc-compound, which separates in nodules, washed with cold water. The zinc-compound is then decomposed by boiling with  $Pb(OH)_2$ , the filtrate is evaporated, and the mixture of creatine and creatinine digested with cold absolute alcohol, which dissolves the creatinine only (Liebig; Dessaignes, *J. Ph.* [3] 32, 42; Heintz; Loebe, *J. pr.* 82, 170; *Rep. chim. pure*, 1861, 25; Neubauer, *A.* 119, 27; Socoloff, *A.* 78, 243; Grocco, *C. C.* 1887, 17).—2. From urine, after adding  $\frac{2}{3}$  vol. saturated aqueous  $NaOAc$ , by fractional ppn. with  $HgCl_2$ . A spherical salt ( $C_4H_7HgN_5O_2HCl$ ), 3  $HgCl_2$ , 2aq is obtained, which is suspended in water and decomposed by  $H_2S$ . The filtrate on evaporation deposits creatinine hydrochloride, whence  $Pb(OH)_2$  liberates creatinine (Johnson, *Pr.* 42, 365; 43, 493).

**Properties.**—Monoclinic prisms (anhydrous) or efflorescent prisms (containing 2 aq). Neutral to litmus (Salkowski, *H.* 12, 211). V. sol. hot water, m. sol. hot alcohol. According to Johnson (*Pr.* 43, 493) there are two varieties of creatinine, differing in reducing power, solubility, and character of their gold salts. Each exists in efflorescent and in tabular form. 1 part of tabular creatinine from urine dissolves in 10.78 pts. water at 17°, and in 362 pts. alcohol at 17°, and its Pt salt dissolves in 14.1 pts. water at 15°; on the other hand, 1 pt. of tabular creatinine from creatine dissolves in 10.68 pts. water at 16.5°, and in 324 pts. alcohol at 18.5°, while its Pt salt requires 24.4 pts. water at 15°. According to Liebig, 1 pt. creatinine dissolves in 11.5 pts. water at 16°, and in 102 pts. alcohol at 16°.

**Reactions.**—1. In alkaline solutions it is slowly converted by taking up water into creatine (Dessaignes, *J. Ph.* [3] 82, 41).—2. Boiling with water and  $HgO$  gives methyl-guanidine.—3. Baryta-water at 100° gives  $NH_3$  and methyl-hydantoin (Neubauer, *A.* 137, 289).—4.  $KMnO_4$  gives oxalic acid and methyl-guanidine.

**Detection.**—1. A small quantity of Fehling's solution at 60° gives a white flocculent pp., consisting of a compound of creatinine with cuprous oxide. 1 mol. creatinine can reduce about  $\frac{1}{2}$  mol.  $CuO$  (Worm-Müller, *J. Th.* 1881, 76; Maschke, *Fr.* 17, 134). According to Johnson (*Pr.* 42, 365; 43, 493) the creatinine obtained from crea-

tine has not the same reducing power as that from urine, the reducing effect of 3 mols. glucose being equal to that of 5 mols. of the former, but only 4 mols. of the latter.—2. If a dilute solution of sodium nitroprusside is added to a solution of creatinine and dilute NaOH slowly dropped in, a ruby-red colouration is produced. By this test the presence of creatinine in urine can be demonstrated. With creatine no colour is produced, unless it is previously converted into creatinine by boiling with a dilute acid; in this way the presence of creatine in milk can be proved (Weyl, *B.* 11, 2175). On acidifying and warming prussian blue is formed (Salkowski, *H.* 4, 133; Colasanti, *G.* 17, 129). According to Guareschi (*C. C.* 1887, 580) this reaction is given also by thio-hydantoin, methyl-hydantoin, and other compounds containing the group  $N.CH_2.CO.N$ .

**Salts.**— $B'HCl$ : prisms (from alcohol) or laminae (from water).— $B'H.AuCl_4$ . According to Johnson this salt when prepared from creatinine derived from creatine is decomposed by ether, but when prepared from urinary creatinine it is not affected by ether.— $B_2H_2PtCl_6.2aq$ : orange prisms. Solubility: *v. supra*.— $B'HI$ : large crystals (from water).— $B'_2H_2SO_4$ : dimetric tables (from dilute alcohol).— $B'_2ZnCl_2$ : monoclinic prisms (Schmidt, *A.* 61, 332). Insol. absolute alcohol. *S.* 1.86 at 15°; 3.65 at 100°. *S.* (98 p.c. alcohol) 0.108 at 15°; 0.174 at 100°.— $B'_2H_2ZnCl_2$ : large crystals, *v. sol.* water and alcohol (Dessaingnes, *J. Ph.* [3] 32, 43). NaOAc added to its solution pps.  $B'_2ZnCl_2$  (Neubauer, *A.* 120, 267).— $B'_2CdCl_2$ : more soluble in water than  $B'_2ZnCl_2$ .— $B'_2Hg(NO_3)_2.HgO$ : crystalline pp. formed by adding aqueous mercuric nitrate to a conc. solution of creatinine.— $(B'AgNO_3)_2.Ag_2O$ : delicate white needles (from water).

(a). Nitroso-creatinine (?)  $C_4H_5N_3O_2$ . [210°]. Formed, together with its isomeride, by passing nitrous acid gas into a conc. solution of creatinine. It is much less soluble in water than its (8)-isomeride (Dessaingnes, *C. R.* 41, 1258; *A.* 97, 339; Märcker, *A.* 133, 305). Crystalline powder, *sl. sol.* cold water, *v. sl. sol.* alcohol. HCl at 100° converts it into methyl-parabanic acid,  $NH_2$ , and oxalic acid (Strecker, *A.* 118, 151). Br forms  $C_4H_5BrN_3O_2$  (?), a neutral crystalline substance, *v. sol.* water. EtI at 160° followed by  $Ag_2O$  gives extremely soluble needles of  $C_4H_5NO_4$  [162°]. **Salts.**— $B'HCl.aq$ .— $B_2H_2PtCl_6$ .— $B'HNO_3$ .

(8). Nitroso-creatinine  $C_4H_5N_3O_2$ . [195°]. Formed as above. Nodules, *v. sol.* water. **Salts.**— $B'HCl$ : laminae; *v. e. sol.* cold water.— $B'_2H_2PtCl_6$ .

**Ethyl-creatinine**  $C_4H_5EtN_3O$ . From creatinine and EtI at 100°; the resulting hydriodide being decomposed by moist  $Ag_2O$  (Neubauer, *A.* 119, 50; 120, 257). Needles (containing  $aq$ ). *V. e. sol.* alcohol, insol. ether.— $B'HCl$ : needles, *v. e. sol.* alcohol and water, insol. ether.— $B'_2H_2PtCl_6$ .— $B'HI$ : needles.

**Xantho-creatinine**  $C_4H_5N_3O$ .

**Occurrence.**—In muscular tissue (Gantier, *Bl.* [2] 48, 18) and in human urine, especially during fatigue (Monari, *G.* 16, 638).

**Properties.**—Sulphur-coloured crystals, having a slightly bitter taste. On warming it smells like acetamide. It has a double action on litmus,

turning blue litmus red, and sensibly bluing red litmus.

**Reactions.**— $ZnCl_2$  gives a similar pp. to creatine,  $B'_2ZnCl_2$ .  $AgNO_3$ , a flocculent pp., *sol. hot* water, crystallising in needles. Ppd. after some time by sodium phosphomolybdate. Its hydrochloride forms feathery crystals; its platinum chloride crystallises in long soluble bundles.

**Chruso-creatinine** *v. p.* 171.

**CRENIC ACID** (*κρηνική*). Said by Berzelius (*P.* 13, 84; 29, 3, 238) to occur in vegetable mould and in the ochreous deposits of ferruginous waters. The deposit is boiled with potash, and the filtrate treated with HOAc and cupric acetate as long as a dark-brown pp. continues to form. This pp. contains a picroenic acid. The filtrate is neutralised with ammonium carbonate, more cupric acetate is added, and the liquid heated to 80°; cupric cuprate is then ppd. Crenic acid is pale yellow and uncrystallisable; apicroenic acid is brown and *sl. sol.* water. According to Mulder (*A.* 36, 243) crenic acid is  $C_6H_{12}O_8$ , while apicroenic acid is  $C_6H_{12}O_{12}$ . Crenic acid dissolves ferrous carbonate (Boutigny, *C. R.* 58, 247).

**CREOSOL**  $C_9H_8O_2$  *i.e.*  $C_6H_4Me(OMe)(OH)$  [1.3:4]. Mol. w. 138. (220°). *S.G.* 1.0894. Occurs among the products of the distillation of beech wood and of gum guaiacum (Hlasiwetz, *A.* 106, 339). Formed also by distilling homovanillic acid  $C_8H_8(OMe)(OH).CH_2.CO_2H$  with lime (Tiemann & Nagai, *B.* 10, 206). Aromatic liquid, *sl. sol.* water, miscible with alcohol, ether, and benzene.  $Fe_2Cl_6$  gives a green colour. HI or potash-fusion convert it into  $C_6H_4Me(OH)_2$  (Tiemann & Koppe, *B.* 14, 2025).  $PCl_5$  gives  $C_6H_4Me(OMe)Cl$  (?) (185°) *S.G.* 1.028 which gives a green colour with  $Fe_2Cl_6$  and a pp. of  $AgCl$  with  $AgNO_3$  (Biechle, *A.* 151, 115).

**Salts.**— $KC_9H_7O_2.2aq$ : needles, *v. sol.* water and alcohol.— $KHA'.aq$ : thin prisms; decomposed by water into  $KA'$  and creosol.— $BaA'.3aq$ : small scales.

**Methyl ether**  $C_9H_8Me(OMe)_2$ . (218°). Occurs in beech wood creosote (Tiemann & Mendelssohn, *B.* 8, 1137). Formed by fusing papaverine with KOH (Goldschmidt, *M.* 4, 705). Also from creosol, KOH, and MeI. Gives no colour with  $Fe_2Cl_6$ .

**Ethyl ether**  $C_9H_8Me(OMe)(OEt)$ . Oil.

**Acetyl derivative**  $C_9H_7Me(OMe)(OAc)$ . (247°). Oil (Tiemann, *B.* 9, 418; 10, 58).

**CREOSOL SULPHONIC ACID**

$C_9H_7Me(OMe)(OH)(SO_3H)$ . From creosol and conc.  $H_2SO_4$  at 60° (Biechle, *A.* 151, 109; Tiemann & Koppe, *B.* 14, 2026). Hygroscopic syrup.— $KA'$ : needles; its aqueous solution is coloured blue by  $Fe_2Cl_6$ .— $BaA'$ .— $PBA'$ .

**CREOSOL CARBOXYLIC ACID** *v. Methyl derivative of Di-oxy-toluic acid.*

**CREOSOTE** (*κρησώτης*).—A mixture of substances of a phenolic character, which may be extracted by alkalis from the tar obtained by the dry distillation of wood. Rhenish beech tar creosote contains phenol, cresols, guaiacol, phlorol, and creosol (Reichenbach, *Schw.* *J.* 66, 301, 345; 67, 1, 57; 68, 353; Etting, *A.* 6, 209; Laurent, *C. R.* 11, 124; 19, 574; Deville, *A. Ch.* [3] 12, 228; Goup-Besanez, *A.* 78, 281; 86, 223; 143, 129; *Z.* [2] 4, 383; Voelckel, *A.* 86, 93; 87, 306; Hlasiwetz, *A.* 106, 339; Simon, *P.* 32, 129; Hübschmann, *A.* 11, 40; Köne, *A.* 16,

68; Flickiger, *Ph.* [3] 2, 1008; Ruot, *Bl.* [2] 8, 875; H. Müller, *Z.* 1864, 40; Marasse, *B.* 1, 99; 2, 71; *Z.* [2] 4, 502; 5, 348; Frisch, *J. pr.* 100, 228; J. Williams, *C. C.* 1873, 167; Hofmann, *B.* 8, 66; Tiemann, *a.* Mendelsohn, *B.* 8, 1136; Clark, *Ph.* [3] 8, 1037; Wätzel, *Ar. Ph.* [3] 10, 180.

**CRESAURIN** *v.* *Anhydride of* TRI-OXY-TRI-TOLYL-CARBINOL.

**CRESOLS**  $C_6H_4O$  i.e.  $C_6H_4Me(OH)$ . Mol. w. 108. *Oxy-toluenes. Methyl phenols.*—The three cresols occur in the tar obtained by the destructive distillation of coal, beech wood, and pine wood (Schotten *a.* Tiemann, *B.* 11, 783; Schulze, *B.* 20, 410; Duclos, *A.* 109, 136; Marasse, *A.* 152, 64). They are best obtained in a state of purity from the corresponding toluidines by the diazo-reaction, or from the toluene sulphonic acids by potash-fusion. A cresol is formed by oxidising toluene in presence of  $Al_2Cl_3$  (Friedel *a.* Crafts, *C. R.* 86, 884). Acid sulphates of the three cresols occur in horse's urine, and cresols are converted into such acids when given to animals in their food (Baumada *a.* Herter, *B.* 9, 1889). The three cresols, by heating with ammoniacal  $ZnBr_2$  and  $NH_4Cl$ , or with ammoniacal  $ZnCl_2$  and  $NH_4Cl$ , are converted into the corresponding toluidines and di-tolyl-amines in variable proportion (Merz *a.* Müller, *B.* 20, 544).

*Azo-compounds of the three cresols.*—*p*-Cresol combines with diazo-compounds as easily as phenols not substituted in the *p*-position, the diazo-residue entering the *o*-position to the OH. Disazo-compounds of *p*-cresol cannot be obtained. In the *azo*-compounds of *o*- and *m*-cresol the diazo-residue takes the *p*-position to the OH. Both readily yield diazo-compounds, in which the two *azo*-residues stand in the *p*- and *o*-position to the hydroxyl, and hence are *meta* to each other. *o*- and *m*-Cresol readily give nitroso-derivatives, but *p*-cresol does not (Nölting *a.* Kohn, *B.* 17, 351).

*o*-Cresol  $C_6H_4Me(OH)$  [2:1]. [30°]. (190·8°). S.G.  $\frac{4}{5}$  1·0053;  $\frac{3}{4}$  1·0573. C.E. (0°-10°) ·00072 (Pinette, *A.* 243, 37). H. F. 50,992 (liquid); —3250 (solid) (Stohmann, *J. pr.* [2] 34, 311).

*Formation.*—1. By fusing toluene *o*-sulphonic acid with KOH (Engelhardt *a.* Latschinoff, *Z.* 1869, 620).—2. From *o*-toluidine.—3. By distilling (1, 2, *c*)-oxy-toluic acids with lime.—4. By heating carvacrol with  $P_2O_5$ , and fusing the resulting *o*-tolyl phosphate with KOH (Kekulé, *B.* 7, 1006).—5. By treating camphor with  $ZnCl_2$  (Reuter, *B.* 16, 624).

*Properties.*—Crystalline. Converted by potash-fusion into salicylic acid.  $KClO_4$  and  $HCl$  give di- and tri-chlorotoluquinone (Southworth, *A.* 168, 278). Br gives  $C_6H_3Br_2Me(OH)$  [57°] (Werner, *Bl.* [2] 46, 278). Excess of Br gives  $C_6H_2Br_3(OBr)$ .

*Salt.*— $(C_6H_4MeO)_2Al$ . From *o*-cresol, Al, and a little iodine (Gladstone *a.* Tribe, *C. J.* 49, 26). Black, vitreous mass, forming a dark-green solution in benzene, decomposed by water and by alcohol. On distillation it yields di-*o*-tolyl oxide ( $C_6H_4Me)_2O$  (c. 275°), *o*-cresol, and a compound  $C_{12}H_{10}O$ , crystallising in colourless plates.

*Benzoyl derivative*  $C_6H_4OBz$ . Oil.

*Methyl ether*  $C_6H_4Me(OMe)$ . (171·3°). S.G.  $\frac{4}{5}$  ·9957. S.V. 146·1. C.E. (0°-10°) ·00084 (Pinette, *A.* 243, 37; cf. Körner, *Z.* [2] 4, 327).

*Ethyl ether*  $C_6H_4Me(OEt)$ . (184·8°). S.G.  $\frac{4}{5}$  ·9679. S.V. 170·9. C.E. (0°-10°) ·0009 (Pinette, *A.* 243, 88). From alcohol,  $EtBr$  and potassium cresol by boiling (Staedel, *A.* 217, 41). The yield is 67 p.c. Also from diazo-toluene sulphate and absolute alcohol (Remsen *a.* Orndorff, *Am. J.* 9, 394).  $HNO_3$  converts it into  $C_6H_4(NO_2)_2Me(OEt)$  [51°] and a little  $C_6H_4(NO_2)_2Me(OH)$  [82°].

*Ethylene ether*  $(C_2H_5O)_2C_6H_4$ . [79°]. White plates, sl. sol. cold alcohol.

*Propyl ether*  $C_6H_4Me(OPr)$ . (204·1°). S.G.  $\frac{4}{5}$  ·9517. S.V. 195. C.E. (0°-10°) ·00087 (Pinette).

*Butyl ether*  $C_6H_4Me(OC_4H_9)$ . (223°). S.G.  $\frac{4}{5}$  ·9437. S.V. 218·4. C.E. (0°-10°) ·00092.

*Heptyl ether*  $C_6H_4Me(OC_7H_{15})$ . (277·5°). S.G.  $\frac{4}{5}$  ·9243. S.V. 292·95. C.E. (0°-10°) ·00083.

*Octyl ether*  $C_6H_4Me(OC_8H_{17})$ . (292·9°). S.G. ·9231. S.V. 317·9. C.E. (0°-10°) ·00084.

*Benzyl ether* *v.* vol. i. p. 490.

*m*-Cresol  $C_6H_4Me(OH)$ . [4°]. (202·8°). S.G.  $\frac{4}{5}$  1·0498. S.V. 123·2. C.E. (0°-10°) ·00078 (Pinette, *A.* 243, 40).  $\mu_A$  1·5316 at 25°. H.F. 53,044 (Stohmann, *J. pr.* [2] 34, 311). Occurs in coal-tar cresol, together with its *m*- and *p*-isomerides (Schulze, *B.* 20, 409; cf. Ihle, *J. pr.* [2] 14, 442). From thymol (100 g.) and  $P_2O_5$  (40 g.); propylene being given off; the resulting *m*-tolyl-phosphoric acid being fused with KOH. The yield is 51 p.c. (Staedel, *A.* 217, 46; cf. Engelhardt *a.* Latschinoff, *Z.* 1869, 621; Southworth, *A.* 168, 268; Tiemann *a.* Schotten, *B.* 11, 769). Formed also by distilling *m*-oxy-uvic acid with lime (Oppenheim *a.* Pfaff, *B.* 8, 886), and by distilling aluminium thymol (Gladstone *a.* Tribe, *C. J.* 41, 12). Formed also by the action of dry oxygen upon toluene in presence of  $Al_2Cl_3$  (Friedel *a.* Crafts, *A. Ch.* [6] 14, 436).

*Properties.*—Liquid. Can be solidified by throwing a crystal of phenol into the liquid cooled in a freezing-mixture (Staedel, *B.* 18, 343). Its aqueous solution is coloured bluish-violet by  $FeCl_3$ . Fusion with KOH gives *m*-oxy-benzoic acid.  $HCl$  and  $KClO_4$  from di-chloro-toluquinone Br (3 mols.) gives  $C_6H_3Br_2Me(OH)$  [82°]; excess of Br forms  $C_6H_2Br_3Me(OBr)$  which liberates iodine from KI (Werner, *Bl.* [2] 46, 276).

*Benzoyl derivative*  $C_6H_4OBz$ . [38°]. (c. 295°).

*Methyl ether*  $C_6H_4Me(OMe)$ . (177·2°). S.G.  $\frac{4}{5}$  ·9891. S.V. 147·45. C.E. (0°-10°) ·00092 (Pinette, *A.* 243, 40). H.F.p. 39,748 ( $C_{10}O_2 = 94$ ;  $H_{10}O = 69$ ) (Stohmann, *J. pr.* [2] 35, 24).

*Ethyl ether*  $C_6H_4Me(OEt)$ . (192°). S.G.  $\frac{4}{5}$  ·965. S.V. 172. C.E. (0°-10°) ·0009 (Pinette, *A.* 243, 41). From *m*-diazo-toluene sulphate and alcohol (Remsen *a.* Orndorff, *Am. J.* 9, 394).

*Propyl ether*  $C_6H_4Me(OPr)$ . (210·6°). S.G.  $\frac{4}{5}$  ·9484. S.V. 196·2. C.E. (0°-10°) ·0009.

*Butyl ether*  $C_6H_4Me(OC_4H_9)$ . (229·2°). S.G.  $\frac{4}{5}$  ·9407. S.V. 220·45. C.E. (0°-10°) ·00092.

*Heptyl ether*  $C_6H_4Me(OC_7H_{15})$ . (283·2°). S.G.  $\frac{4}{5}$  ·9202. S.V. 296·7. C.E. (0°-10°) ·00084.

*Octyl ether*  $C_6H_4Me(OC_8H_{17})$ . (298·9°). S.G.  $\frac{4}{5}$  ·9194. S.V. 321·95. C.E. (0°-10°) ·00086 (Pinette, *A.* 243, 43).

*Benzyl ether* *v.* vol. i. p. 490.

*m*-Cresyl ether *v.* Di-*m*-TOLYL OXIDE.

*p*-Cresol  $C_6H_4Me(OH)$ . [36°]. (201·8°). S.G.  $\frac{4}{5}$  ·9962;  $\frac{3}{4}$  1·0622. S.V. 123·45. C.E. (0°-10°)

•00086 (Pinette, A. 243, 43). H.F. 51,100 (solid); -2459 (liquid) (Stohmann, J. pr. [2] 34, 311).

**Occurrence.**—In coal-tar (H. Buff, B. 4, 378). As *p*-tolyl sulphuric acid in urine of horses, of cows, and sometimes of men (Brieger, H. 4, 204).

**Formation.**—1. By fusing its sulphonate with KOH (Wurtz, A. 144, 121; 156, 258). If the mixture of sulphonic acids of crude cresol is treated with excess of baryta, basic barium *p*-cresol-sulphonate is ppd. (Armstrong a. Field, C. N. 29, 282; Baumann, H. 6, 185).—2. From *p*-toluidine.—3. Gd. by putrefaction of ox-brain at 40° (F. Stöckly, J. pr. [2] 24, 17). Found also among the products of putrefaction of horses' liver, tyrosine, *p*-oxy-phenyl-acetic acid, and *p*-oxy-phenyl-propionic acid (Baumann a. Brieger, H. 8, 149; 4, 304; Weyl, H. 3, 312).—4. Together with carpane by the dry distillation of podocarpic acid or its Ca salt (Oudemans, A. 170, 259).—5. By heating *p*-oxy-phenyl-acetic acid with CaO (Salkowski, B. 12, 1440).

**Preparation.**—From *p*-toluidine by diazotisation in presence of excess of H<sub>2</sub>SO<sub>4</sub>.

**Properties.**—Prisms. Its aqueous solution is coloured blue by FeCl<sub>3</sub>. Potash-fusion converts it into *p*-oxy-benzoic acid. HCl and KClO<sub>4</sub> give no chlorinated toluquinone (Southworth, A. 168, 271). Br (2 mols.) gives a pp. of C<sub>7</sub>H<sub>4</sub>Br<sub>2</sub>Me(OH) [49°], but a larger quantity of Br (3 mols.) gives C<sub>7</sub>H<sub>4</sub>Br<sub>3</sub>Me(OBr), while a large excess forms C<sub>7</sub>H<sub>4</sub>Br<sub>3</sub>(OH) (Werner, Bl. [2] 46, 278). Chloral forms C<sub>7</sub>H<sub>4</sub>OC<sub>2</sub>H<sub>4</sub>ClO [52°–56°] (Mazzara, G. 13, 272).

**Salt.**—(C<sub>7</sub>H<sub>4</sub>MeO).Al. On distillation it gives a small quantity of di-*p*-tolyl oxide and a ketone C<sub>11</sub>H<sub>10</sub>O [168°] (307°). S. (alcohol) 4 at 20°; 2.5 at 78°. S. (benzene) 3.3 at 21°. V.D. 209.1 (Gladstone, C. J. 41, 8).

**Acetyl derivative** C<sub>7</sub>H<sub>4</sub>OAc. (c. 210°). Oil (Fuchs, B. 2, 626).

**Benzoyl derivative** C<sub>7</sub>H<sub>4</sub>OBe. [70–6°]. H.F. 69,010 (Stohmann, J. pr. [2] 36, 8; cf. Guareschi, A. 171, 142).

**Lauryl derivative** C<sub>7</sub>H<sub>4</sub>O.C<sub>11</sub>H<sub>21</sub>O. [28°]. (220°) at 15 mm. (Kraft a. Birger, B. 17, 1378).

**Myristyl derivative** C<sub>7</sub>H<sub>4</sub>O.C<sub>13</sub>H<sub>27</sub>O. [39°]. (240°) at 15 mm. (K. a. B.).

**Palmityl derivative** C<sub>7</sub>H<sub>4</sub>O.C<sub>15</sub>H<sub>31</sub>O. [47°]. (258°) at 15 mm.

**Stearyl derivative** C<sub>7</sub>H<sub>4</sub>O.C<sub>17</sub>H<sub>35</sub>O. [54°]. (276°) at 15 mm. (K. a. B.).

**Methylether** C<sub>7</sub>H<sub>4</sub>Me(OMe). (175°). S.G. § 9668. S.V. 147.7. C.E. (0–10°) •00084 (Pinette, A. 243, 44; Körner, Bull. Acad. Belg. [2] 24, 154).

**Ethyl ether** C<sub>7</sub>H<sub>4</sub>Me(OEt). (189–9°). S.G. § 9662. S.V. 172.1. C.E. (0°–10°) •00086 (Pinette, A. 243, 44). H.F. p. 46,880 (Stohmann, J. pr. [2] 35, 24). Formed (11½ p.c.), together with aldehyde and toluene (18 p.c.), by decomposing *p*-diazotoluene sulphate with alcohol (Hensen a. Orloff, Am. 9, 394). HNO<sub>3</sub> (S.G. 1.5) converts it into di-nitro-*p*-cresol [84°] and its ether [75°] (Staedel, B. 14, 898). K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and HOAc form (4:1) C<sub>7</sub>H<sub>4</sub>(OEt)CO<sub>2</sub>H.

**Ethylene ether** (C<sub>7</sub>H<sub>4</sub>MeO)<sub>2</sub>C<sub>2</sub>H<sub>4</sub>. [135°]. (297°) (Fuchs, B. 2, 624).

**Propyl ether** C<sub>7</sub>H<sub>4</sub>Me(OPr). (210–4°). S.G. § 9497. S.V. 196. C.E. (0°–10°) •00089 (Pinette, A. 243, 45).

Vol. II.

**Butyl ether** C<sub>7</sub>H<sub>4</sub>Me(OC<sub>4</sub>H<sub>9</sub>). (229–6°). S.G. § 9419. S.V. 220.8. C.E. (0°–10°) •00092.

**Heptyl ether** C<sub>7</sub>H<sub>4</sub>Me(OC<sub>7</sub>H<sub>15</sub>). (283–3°). S.G. § 9228. S.V. 297.7. C.E. (0°–10°) •0009.

**Octyl ether** C<sub>7</sub>H<sub>4</sub>Me(OC<sub>8</sub>H<sub>17</sub>). (298°). S.G. § 9199. S.V. 322.4. C.E. (0°–10°) •00088.

**Benzylether** v. vol. i, p. 490.

**Nitro-benzyl ether** v. *p*-TOLYL NITRO-BENZYL OXIDE.

***p*-Cresyl ether** v. Di-*p*-TOLYL OXIDE.

**Derivatives of cresols** v. AMIDO-CRESOL, BROMO-CRESOL, CHLORO-CRESOL, IODO-CRESOL, NITRO-CRESOL.

**CRESOL DICARBOXYLIC ACIDS** v. OXY-UVITIC, OXY-METHYL-ISO-PHTHALIC, and OXY-METHYL-TEREPHTHALIC ACIDS.

***o*-CRESOL-PHTHALEIN** C<sub>22</sub>H<sub>18</sub>O<sub>4</sub>, i.e.

(C<sub>6</sub>H<sub>4</sub>MeOH).C<C<sub>6</sub>H<sub>4</sub>>CO. [214°].

**Preparation.**—By heating *o*-cresol (2 pts.), phthalic anhydride (3 pts.), and stannic chloride (2 pts.) at 120°–125°. From the fused mass thus obtained the undecomposed cresol is separated by steam-distillation; and the phthalein is purified by recrystallisation from alcohol (Baeyer a. Franke, A. 202, 153).

**Properties.**—Flesh-red crystals, v. sol. alcohol and ether, m. sol. hot water; sol. caustic alkalis with violet colouration, showing a broad absorption band in the red.

**Reactions.**—1. With bromine it forms a di-bromo-derivative together with a bromo-oxy-tolyl-benzoic acid CO<sub>2</sub>H.C<sub>6</sub>H<sub>4</sub>.CO.C<sub>6</sub>H<sub>4</sub>MeBr(OH) [228°].—2. With nitric acid it gives a di-nitro-derivative.—3. Zinc-dust forms the corresponding phthalin.—4. Phthalic anhydride and conc. sulphuric acid give oxy-methyl-anthraquinone.

**Di-acetyl derivative** C<sub>22</sub>H<sub>14</sub>Ac<sub>2</sub>O<sub>4</sub>. [75°]: white amorphous mass.

**Di-benzoyl derivative** C<sub>22</sub>H<sub>14</sub>Bz<sub>2</sub>O<sub>4</sub>. [196°].

**Di-bromo-derivative** C<sub>22</sub>H<sub>14</sub>Br<sub>2</sub>O<sub>4</sub>. [255°]. Crystalline. Sol. alkalis with blue, and in conc. sulphuric acid with rose-red, colouration. Converted by phthalic anhydride and sulphuric acid to bromo-oxy-methyl-anthraquinone.

**Di-nitro-derivative** C<sub>22</sub>H<sub>14</sub>(NO<sub>2</sub>)<sub>2</sub>O<sub>4</sub>. [248°]: yellow crystals. Sol. Na<sub>2</sub>CO<sub>3</sub>Aq with red-brown colouration.

***o*-Cresol-phthalin** C<sub>20</sub>H<sub>16</sub>O<sub>4</sub>, i.e.

(C<sub>6</sub>H<sub>4</sub>MeOH).CH.C<sub>6</sub>H<sub>4</sub>.CO<sub>2</sub>H. [218°]. Prepared by reduction of *o*-cresol phthalein with zinc-dust and KOH (Franke, A. 202, 168; B. 12, 243). Small concentrically grouped needles; sol. water and alcohol, slowly oxidised to *o*-cresol-phthalein by exposure to air. By the action of H<sub>2</sub>SO<sub>4</sub> it gives *o*-cresol phthalidin.

**Di-acetyl derivative** C<sub>20</sub>H<sub>14</sub>Ac<sub>2</sub>O<sub>4</sub>. [139°]. Crystalline powder. Sol. acetone. Converted by conc. H<sub>2</sub>SO<sub>4</sub> into the phthalidin.

**Di-bromo-derivative** C<sub>20</sub>H<sub>14</sub>Br<sub>2</sub>O<sub>4</sub>. [236°].

***p*-Cresol-phthalein anhydride** C<sub>22</sub>H<sub>18</sub>O<sub>4</sub>, i.e.

O<C<sub>6</sub>H<sub>4</sub>Me>C<C<sub>6</sub>H<sub>4</sub>>CO. [246°].

From *p*-cresol, phthalic anhydride and H<sub>2</sub>SO<sub>4</sub> at 160°. Excess of *p*-cresol is removed by steam, and the residue washed with boiling dilute KHO (Drewsen, A. 212, 340). Plates or prisms (from alcohol). Sol. alcohol, ether, and benzene; v. sol. CHCl<sub>3</sub>; insol. ligroin, KHO and weak acids. Conc. H<sub>2</sub>SO<sub>4</sub> gives a green fluorescence. Sublimes

T

unchanged. Reduced by zinc-dust and AcOH to the phthalin anhydride. Fused with KHO it yields di-oxy-di-methyl benzophenone. [105°]. Heating with conc. H<sub>2</sub>SO<sub>4</sub> yields methyl-erythro-oxy-anthraquinone.

*p*-Cresol phthalin anhydride C<sub>12</sub>H<sub>10</sub>O<sub>3</sub>, i.e.  $\text{O} \begin{array}{c} \text{C}_6\text{H}_4\text{Me} \\ \text{C}_6\text{H}_4\text{Me} \end{array} \text{CH}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ . [210°]. From the preceding by reduction with zinc-dust and AcOH; crystallises from CHCl<sub>3</sub>. V. sol. alcohol, benzene, ether, and acetic acid. Sol. conc. H<sub>2</sub>SO<sub>4</sub> forming a brown solution (Drewsen, A. 212, 340).

*o*-CRESOL SULPHONIC ACID C<sub>7</sub>H<sub>6</sub>SO<sub>3</sub>, i.e. C<sub>6</sub>H<sub>4</sub>Me(OH)(SO<sub>3</sub>H) [1:2:4]. From *o*-toluidine sulphonic acid by displacing NH<sub>2</sub> by OH through the diazo-reaction (Hayduck, A. 172, 204; 174, 345). Formed also in small quantity by sulphonating *o*-cresol in the cold. At high temperatures it is the only product of this sulphonation (Engelhardt & Latschinoff, Z. 1869, 621; Hantke, B. 20, 3209). Does not crystallise. Potash-fusion converts it into salicylic acid, together with small quantities of (1,2,4)-di-oxy-benzoic acid.

**Salts.**—BaA', 1½aq: extremely soluble aggregates of monoclinic prisms (Hayduck). —BaA', 2aq (E. a. L.). —BaA': amorphous (Hantke). —KA', 1aq: short needles (from dilute alcohol).

#### Methyl derivative

C<sub>7</sub>H<sub>6</sub>Me(OMe)(SO<sub>3</sub>H). Formed by boiling *o*-diazotoluene sulphonic acid with MeOH. Syrup. —BaA', 2aq: small laminæ.

#### Ethyl derivative

C<sub>7</sub>H<sub>6</sub>Me(OEt)(SO<sub>3</sub>H). Formed by boiling *p*-diazotoluene sulphonic acid with alcohol (Paysan, A. 221, 214, 363; Hayduck, A. 172, 215). —KA', 2aq. —BaA', 2aq (P.). —BaA', 3aq (H.). —PbA', 3aq. The amide C<sub>7</sub>H<sub>6</sub>Me(OEt).SO<sub>2</sub>NH<sub>2</sub> crystallises in laminæ [137°]; the chloride is an oil.

*o*-Cresol sulphonic acid C<sub>7</sub>H<sub>6</sub>Me(OH).SO<sub>3</sub>H [1:2:5]. From the corresponding toluidine sulphonic acid by boiling the diazo-salt with water (Neville & Winther, C. J. 37, 631). The chief product of the sulphonation of *o*-cresol in the cold (Hantke, B. 20, 3209). Very deliquescent needles.

**Reactions.**—1. At 140° it is split up by water into *o*-cresol and H<sub>2</sub>SO<sub>4</sub>. —2. HNO<sub>3</sub> (1 part) with water (2 or 3 parts) converts it into di-nitro-*o*-cresol, [86°]. —3. Potash-fusion gives salicylic acid and very small quantities of a di-oxy-benzoic acid which is turned blue by Fe<sub>2</sub>Cl<sub>6</sub>.

**Salts.**—BaA', 2½aq (Gerver, A. 169, 386). Needles (from dilute alcohol). Gives a violet colour with Fe<sub>2</sub>Cl<sub>6</sub>. —BaA': large sparingly soluble plates (Hantke). —KA': very soluble pearly plates (H.). —CuA', 5aq: tables. —PbA', 2½aq (G.). Small needles.

#### Ethyl derivative

C<sub>7</sub>H<sub>6</sub>Me(OEt)(SO<sub>3</sub>H) [1:2:5]. From C<sub>7</sub>H<sub>6</sub>Me(NH<sub>2</sub>).SO<sub>3</sub>H, by heating its diazo-derivative with alcohol (Foth, A. 230, 306). —BaA', 4aq.

*m*-Cresol sulphonic acid C<sub>7</sub>H<sub>6</sub>Me(OH)(SO<sub>3</sub>H) [1:3:6]. [118°]. From *m*-cresol and H<sub>2</sub>SO<sub>4</sub> at 110° (Clans & Krauss, B. 20, 8089; cf. Engelhardt & Latschinoff, Z. 1869, 622; Nölting & Salis, B. 15, 1862). Plates (containing 2aq) [75°] (from dilute H<sub>2</sub>SO<sub>4</sub>) or (containing 1½aq) [96°] (from conc. H<sub>2</sub>SO<sub>4</sub>). V. sol. water, alcohol, ether, and benzene. Gives a violet colour with

Fe<sub>2</sub>Cl<sub>6</sub>. CrO<sub>3</sub> gives toluquinone. —KA', 2½aq: stellate group of needles with fatty lustre. —CuA', 3aq: tufts of pale-green prisms. —BaA', 2aq: nodules. —BaC<sub>2</sub>H<sub>3</sub>SO<sub>2</sub>2aq.

*p*-Cresol sulphonic acid C<sub>7</sub>H<sub>6</sub>Me(OH)(SO<sub>3</sub>H) [1:4:2]. [188°]. From *p*-toluidine sulphonic acid by the diazo-reaction (Jenssen, A. 172, 237). Long needles (containing 5aq) [99°]. V. sol. water, alcohol, and ether. Hydrolysed by passing steam through its solution in dilute H<sub>2</sub>SO<sub>4</sub> boiling above 120° (Armstrong & Miller, C. J. 45, 148). —BaA': amorphous, v. e. sol. water. Its solution is coloured violet by Fe<sub>2</sub>Cl<sub>6</sub>.

#### Methyl derivative

C<sub>7</sub>H<sub>6</sub>Me(OMe)(SO<sub>3</sub>H). From the diazo-derivative of toluidine sulphonic acid by gently warming with methyl alcohol (Limpriecht & Heffter, A. 221, 352). Its amide crystallises in prisms [150°]; its chloride is an oil. —BaA', 2aq. —KA'.

#### Ethyl derivative

C<sub>7</sub>H<sub>6</sub>Me(OEt)(SO<sub>3</sub>H). Prepared as above, using ethyl alcohol. Formed also by warming diazo-toluene sulphonic acid with alcohol (Remsen & Palmer, Am. 8, 245). —BaA', 3½aq. —KA'. The amide C<sub>7</sub>H<sub>6</sub>Me(OEt).SO<sub>2</sub>NH<sub>2</sub> [136°] (L. a. H.); [144°] (R. a. P.) crystallises in needles. The chloride is an oil.

*p*-Cresol sulphonic acid C<sub>7</sub>H<sub>6</sub>Me(OH)(SO<sub>3</sub>H) [1:4:3]. From *p*-cresol and fuming H<sub>2</sub>SO<sub>4</sub>. Also from the corresponding *p*-toluidine sulphonic acid by the diazo-reaction (Engelhardt & Latschinoff, Z. 1869, 619; Pechmann, A. 173, 203). Syrup. Fe<sub>2</sub>Cl<sub>6</sub> colours its solution blue. Potash-fusion gives *p*-oxy-benzoic acid. —KA', 2aq: laminæ. —BaA': tables. S. 7 at 17° (Baumann, H. 4, 313). —BaC<sub>2</sub>H<sub>3</sub>SO<sub>2</sub>2aq. V. sl. sol. water. —PbA', 3aq. —PbA', 1½aq: laminæ (from alcohol).

#### Cresol sulphonic acid C<sub>7</sub>H<sub>6</sub>Me(OH)(SO<sub>3</sub>H)

[1:7:2x]. Formed by fusing toluene di-sulphonic acid with KOH (Brunner, Sitz. W. [2] 78, 665). Feathery groups of crystals (containing ½aq at 100°) [81°]. Hygroscopic. V. sol. alcohol and ether. —NaA', 2aq. —KA', 2aq: prisms [c. 228°]. —BaA', 2aq. Its solution is turned blue by Fe<sub>2</sub>Cl<sub>6</sub>. —CaA', 1½aq. —PbA', 3aq. —CuA', 8aq. —ZnA', 10½aq.

Cresol sulphonic acids have been obtained by sulphonating cresols by Ducloux (A. 109, 138), and by Armstrong & Field (B. 6, 974), but not sufficiently characterised.

#### *p*-Cresol *exo*-sulphonic acid

C<sub>7</sub>H<sub>6</sub>(OH).CH<sub>2</sub>.SO<sub>3</sub>H [1:4]. From C<sub>7</sub>H<sub>6</sub>(NH<sub>2</sub>).CH<sub>2</sub>.SO<sub>3</sub>H by diazo-reaction (Mohr, A. 221, 221). Deliquescent needles; v. sol. alcohol. The aqueous solution is turned bluish-violet by Fe<sub>2</sub>Cl<sub>6</sub>. —KA', 1½aq. —BaA', 7½aq.

#### Ethyl derivative

C<sub>7</sub>H<sub>6</sub>(OEt).CH<sub>2</sub>.SO<sub>3</sub>H. Prepared by decomposing the diazo-derivative of C<sub>7</sub>H<sub>6</sub>(NH<sub>2</sub>).CH<sub>2</sub>.SO<sub>3</sub>H by boiling with alcohol. —BaA', 2aq.

#### *o*-Cresol disulphonic acid C<sub>7</sub>H<sub>4</sub>Me(OH)(SO<sub>3</sub>H)<sub>2</sub>

[1:2:3:5]. From *o*-toluidine disulphonic acid by diazo-reaction (Limpriecht, B. 18, 2176; H. Hasse, A. 230, 293). Tables of needles. V. sol. water and alcohol. —KA', 1½aq: very soluble needles. —BaA', 8½aq: small needles.

#### Ethyl derivative

C<sub>7</sub>H<sub>4</sub>Me(OEt)(SO<sub>3</sub>H)<sub>2</sub>. From the diazo-derivative of *o*-toluidine disulphonic acid by boiling with alcohol under an extra pressure of 400 mm. —BaA', 2½aq.

#### *m*-Cresol disulphonic acid

C<sub>7</sub>H<sub>4</sub>Me(OH)(SO<sub>3</sub>H)<sub>2</sub>. From *m*-cresol (1 pt.) and

$\text{H}_2\text{SO}_4$  (5 pts.) at  $130^\circ$  (Claus a. Krauss, B. 20, 3089). V. sol. water and alcohol; m. sol. ether and benzene.— $\text{KA}''$  3aq: plates.— $\text{BaA}''$  3aq.

*p*-Cresol disulphonic acid

$\text{C}_6\text{H}_3\text{Me}(\text{OH})(\text{SO}_3\text{H})_2$  [1:4:3:2or6]. From *p*-toluidine di-sulphonic acid by diazo-reaction (Limpricht, B. 18, 2178; E. Richter, A. 230, 322). Needles. V. e. sol. water and alcohol.— $\text{BaA}''$  4aq: needles.— $\text{K}_2\text{A}''$  3aq?: tables.— $\text{PbA}''$  3aq: v. sol. water.

*p*-Cresol disulphonic acid

$\text{C}_6\text{H}_3\text{Me}(\text{OH})(\text{SO}_3\text{H})_2$  [1:4:3:5]. From *p*-cresol sulphonic acid and fuming  $\text{H}_2\text{SO}_4$  (Engelhardt a. Latschinoff, Z. 1869, 620).— $\text{K}_2\text{A}''$  3aq: crystals, v. e. sol. water.— $\text{BaA}''$  23aq: needles, sl. sol. water.

*m*-Cresol trisulphonic acid

$\text{C}_6\text{H}_3\text{Me}(\text{OH})(\text{SO}_3\text{H})_3$ . From *m*-cresol, fuming  $\text{H}_2\text{SO}_4$ , and  $\text{P}_2\text{O}_5$  at  $180^\circ$  (Claus a. Krauss, B. 20, 3089). The Ba salt is v. sol. water.

**CRESORCELLIC ACID** v. (5:3:2:1)-DI-OXY-*o*-TOLUIC ACID.

**CRESORCIN** v. DI-OXY-TOLUENE.

**CRESORCIN-CARBOXYLIC ACID** v. DI-OXY-TOLUIC ACID.

**CRESOTIC ACID** v. OXY-TOLUIC ACID.

**CRESS OIL**. The volatile oil of garden-cress (*Lepidium sativum*) consists to the extent of 75 p.c. of phenyl-acetonitrile (benzyl cyanide) (Hofmann, B. 7, 1293). The volatile oil of water-cress (*Nasturtium officinalis*) consists of phenyl-propionitrile (Hofmann, B. 7, 520).

**CRESYL COMPOUNDS** v. TOLYL COMPOUNDS.

**CROCETIN**  $\text{C}_{22}\text{H}_{34}\text{O}_6$ . Formed by the action of dilute acids on crocin, a sugar (crocose) being the correlative product (Kayser, B. 17, 2231). Red powder. V. sol. alcohol and ether, nearly insol. water. Dissolves in alkalis with a yellow colour. Like crocin it dissolves in  $\text{H}_2\text{SO}_4$  with a blue colour, which slowly becomes violet, red, and finally brown. Stuffs mordanted with stannous chloride acquire, by boiling in a solution of crocetin (from Gardenia), a dingy greenish-yellow colour, which by treatment with ammoniacal water is converted into a brilliant yellow colour, unaltered by light and air. The yellow robes of the Chinese mandarins are dyed with the fruit of the *Gardenia*.

**CROCIN** (the colouring matter of saffron)  $\text{C}_{40}\text{H}_{56}\text{O}_{20}$ . Appears to be identical with the colouring matter of Chinese yellow pods (*Gardenia grandiflora*) (Roehleider, J. pr. 56, 68). Yellow powder. V. sol. water and dilute alcohol, sl. sol. absolute alcohol, nearly insol. ether.

*Preparation*.—The saffron, which has been previously extracted with ether, is soaked in cold water, the colouring-matter is removed from the aqueous solution by animal charcoal, and after drying is extracted from the charcoal by means of 90 p.c. alcohol.

*Reactions*.—It dissolves in  $\text{H}_2\text{SO}_4$  with a deep blue colour, which gradually becomes violet, then red, and finally brown.  $\text{HNO}_3$  also produces a blue colouration, which almost instantaneously passes into brown. By dilute acids it is split up into crocetin  $\text{C}_{22}\text{H}_{34}\text{O}_6$  and a sugar (crocose)  $\text{C}_6\text{H}_{12}\text{O}_6$  (Kayser, B. 17, 2228).

**CROCONAMIC ACID**  $\text{C}_8\text{H}_6\text{NO}_4$ , i.e.  $\text{C}_6\text{O}_4(\text{OH})(\text{NH}_2)$ , or more probably  $\text{C}_6\text{O}_4(\text{NH})(\text{OH})_2$ . *Imido-croconic acid*.—The ammonium salt is

formed by heating the di-anilide of croconic acid with aqueous  $\text{NH}_3$ . Mono-basic acid.

*Salts*.— $\text{A}''\text{NH}_4$ : red prisms with bluish reflex.  $\text{A}''\text{Ag}$  2aq: yellow needles.— $\text{A}''\text{Ba}$  3aq: sparingly soluble small yellow needles.— $\text{BaC}_2\text{H}_3\text{NO}_4$  4aq: sparingly soluble yellow plates (Nietzki a. Benckiser, B. 19, 773; 21, 1856).

**CROCONIC ACID**  $\text{C}_6\text{H}_2\text{O}_4$  or

*Formation*.—1. From the black-residues obtained in the preparation of potassium by Brunner's method (Gmelin, P. 4, 87; A. 37, 58; Liebig, A. 11, 182; P. 33, 90; Heller, J. pr. 12, 230; A. 24, 1; 34, 232; Will, A. 118, 177). When CO is passed over melted potassium and the product is treated with water, a red salt, potassium rhodizonate, is formed. A solution of this salt changes on standing exposed to air to potassium croconate. Excess of alkali converts rhodizonic acid into croconic acid dihydride, which appears to be an intermediate body in the formation of croconic acid from rhodizonic acid (Nietzki, B. 20, 1617).—2. By heating benzene-tri-quinone  $\text{C}_{20}\text{O}_6$  to  $100^\circ$ , or by boiling it with water, CO being evolved.—3. By exposing an alkaline solution of tetra-oxy-quinone  $\text{C}_6(\text{OH})_4\text{O}_2$  to the air, oxalic acid being formed simultaneously.—4. By evaporating hexa-oxy-benzene  $\text{C}_6(\text{OH})_6$ , with dilute KOH in an open dish (Nietzki a. Benckiser, B. 18, 509).

*Preparation*.—By boiling the hydrochloride of diamidotetraoxybenzene  $\text{C}_6(\text{NH}_2)_2(\text{OH})_2$  (1 pt.) with  $\text{K}_2\text{CO}_3$  (4 pts.) precipitated  $\text{MnO}_2$  (3 pts.) and water (60 pts.) for  $\frac{1}{2}$  hour; on adding  $\text{BaCl}_2$  to the filtrate acidified with HCl the sparingly soluble barium croconate separates in golden-yellow plates; the yield is 70 p.c. of the theoretical (Nietzki a. Benckiser, B. 19, 293).

*Properties*.—Sulphur-yellow plates or grains (containing 3aq). V. sol. water, sl. dilute alcohol. Di-basic acid. Forms a sparingly soluble red crystalline anilide. Heated with  $\text{NH}_3$  it gives the tri-imide of leuconic acid. With hydroxylamine it gives the penta-oxim of leuconic acid  $\text{C}_6(\text{NOH})_5$ . By  $\text{H}_2\text{S}$  it is converted into thio-croconic acid  $\text{C}_6\text{H}_2\text{O}_4\text{S}$ . It is reduced by  $\text{SnCl}_2$ ,  $\text{SO}_2$ , or zinc-dust to the colourless hydro-croconic acid  $\text{C}_6\text{H}_4\text{O}_4$ , which is readily reoxidised to croconic acid. By heating potassium croconate with HI it is reduced to 'croconic-acid-hydride' ( $\text{C}_6\text{H}_2\text{O}_4$ ?), whose salts are deep coloured; by further reduction it gives a colourless substance which is readily reoxidised to the hydride. Croconic acid is oxidised by  $\text{HNO}_3$  to leuconic acid  $\text{C}_6\text{O}_4$ .

*Salts*.— $\text{KA}''$ : long dark-yellow needles (N. a. B.).— $\text{K}_2\text{A}''$  2aq: orange needles (G.).— $\text{HKA}''$ : brownish-yellow needles with violet reflex.— $\text{NaKA}''$  2aq: yellow rhombic plates, become red on drying.— $\text{CaA}''$  3aq: yellow powder (W.).— $\text{BaA}''$  13aq: lemon-yellow powder, insol. water, v. sl. sol.  $\text{HClAq}$ .— $\text{PbA}''$  2aq: lemon-yellow pp., insol. water.— $\text{CuA}''$  3aq: sparingly soluble orange needles with blue reflex.— $\text{Ag}_2\text{A}''$ : orange pp.

Aniline salt  $\text{A}''(\text{NH}_2\text{Ph})_2$ : yellow plates, m. sol. water.

*Di-anilide*  $\text{O}_4(\text{HO}_2\text{NPh})_2$ : slender red needles. Formed by heating the aniline salt with

alcohol. V. sl. sol. all solvents but aniline. Dissolves in aqueous alkalis, and on heating the solution croconic acid and aniline are regenerated. Heated with aqueous  $\text{NH}_3$ , it is converted into croconamic acid  $\text{C}_8\text{H}_7\text{NO}_4$  (Nietzki a. Benckiser, B. 19, 772).

**Mono-phenylhydrazide**  $\text{C}_8(\text{OH})_2\text{O}_2(\text{N}_2\text{HPh})$ : [above  $300^\circ$ ]; yellow needles; v. sol. alcohol, insol. water. Di-basic acid.— $\text{K}_2\text{A}''$ : nearly black coppery needles, v. sol. water with a brown colour.

**Tolylene-o-diamide v. Croconic-di-tolu-quinoxaline.**

'Croconic-acid-hydride'  $\text{C}_8\text{H}_4\text{O}_2$  or  $\text{C}_{10}\text{H}_6\text{O}_4$

acid' of Lerch (A. 124, 20). Formed by heating potassium croconate with HI. Its salts are dark-coloured. By further reduction it is converted into a colourless substance, which is readily reoxidised to the hydride.— $\text{C}_8\text{H}_4\text{O}_2 \cdot \text{Ba}2\text{aq}$  or  $\text{C}_{10}\text{H}_6\text{O}_4 \cdot \text{Ba}, 4\text{aq}$ : deep orange crystalline powder or amorphous flocculent pp.— $\text{PbC}_8\text{H}_4\text{O}_2$ : red pp. (Nietzki a. Benckiser, B. 19, 297).

**CROCONIC-TOLUQUINOXALINE**  $\text{C}_{12}\text{H}_8\text{N}_2\text{O}_4$

**o-diamide.** Formed by mixing a cold aqueous solution of croconic acid with a salt of tolylene-o-diamine. Fine needles, with green reflex. Sol. alcohol with a brown colour, insol. water. Di-basic acid.— $\text{A}''\text{K}_2$ : black metallic needles (Nietzki a. Benckiser, B. 19, 776).

**CROCOSE (saffron-sugar)**  $\text{C}_8\text{H}_{12}\text{O}_8$ . Trimetric crystals. Sweet taste. Dextrorotatory. Its reducing power is half that of dextrose. Formed, together with crocetin, by the action of dilute acids on crocin (Kayser, B. 17, 2232; cf. Rochleder a. Mayer, J. 1858, 476; Sitz. W. 29, 3).

**CROSSOPTERINE.** An amorphous alkaloid in the bark of *Crossopteryx Kotschyana* (Hesse, B. 11, 1546).

**CROTACONIC ACID**  $\text{C}_8\text{H}_8(\text{CO}_2\text{H})_2$ . [119°]. Solidifies at  $90^\circ$ . From cyano-crotonic acid which changes spontaneously into acid ammonio crotaconate (Claus, A. 191, 74; B. 10, 822).

**Properties.**—Crystals. Sol. water, alcohol, and ether. At  $140^\circ$  it decomposes, giving off  $\text{CO}_2$  (difference from itaconic, citraconic, &c.). Combines with HBr forming an acid  $\text{C}_8\text{H}_7\text{Br}(\text{CO}_2\text{H})_2$  [141°].

**Salts.**— $(\text{NH}_4)\text{HA}''$ .— $\text{KHA}''$  2aq.— $\text{K}_2\text{A}''$  aq.— $\text{PbA}''$ .— $\text{Ag}_2\text{A}''$ .

**Dimethyl ether**  $\text{Me}_2\text{A}''$ . S.G. 1.14. Sol. alcohol and ether.

**Isomerides:** CITRACONIC, ITACONIC, MESACONIC, and ETHYLDIENE-MALONIC, ACIDS.

**CROTACONIC ACID**  $\text{C}_8\text{H}_8\text{O}_4$ , i.e.

$\text{CH}_3\text{CH}:\text{CH}\cdot\text{CO}_2\text{H}$ . Mol. w. 80. [72°]. ( $185^\circ$  cor.). S. 8 at  $19^\circ$ .  $R_D$  35.71 in a 4.12 p.c. aqueous solution (Kanonnikoff).

**Occurrence.**—In crude wood vinegar (Krämer a. Grodzki, B. 11, 1359). Its name is derived from croton oil, from which it was erroneously supposed to be formed by saponification (Pelletier a. Caventou, J. Ph. 4, 289; 11, 110; Schlippe, A. 105, 1; Geuther, Z. [2] 5, 270).

**Preparation.**—1. By oxidation of crotonic aldehyde (from acetic aldehyde) in the air or

by moist  $\text{Ag}_2\text{O}$  (Kekulé, B. 8, 604; Z. [3] 6, 705).—2. From allyl cyanide (v. vol. i. p. 136) obtained from mustard oil (Will a. Körner, A. 125, 273).—3. By distillation of ( $\beta$ )-oxy-butyric acid (Wislicenus, Z. 1869, 325).—4. By boiling  $\alpha$ -bromo-butyric ether with alcoholic KOH (Hell a. Lauber, B. 7, 560).—5. From isocrotonic acid by intramolecular change brought about by heating to  $175^\circ$  (Hemilian, A. 174, 322).—6. From malonic acid (1 mol.), paraldehyde (1 mol.), and excess of glacial acetic acid at  $100^\circ$  (Komnenos, A. 218, 149). The yield is good (50 p.c.).—7. By heating pyruvic acid (1 pt. f with  $\text{Ac}_2\text{O}$  (5 pts.) and  $\text{NaOAc}$  (5 pts.) at  $170^\circ$  (Homolka, B. 18, 987).—8. By reduction of  $\alpha$ -aceto-acetic ether with sodium-amalgam (Beilstein a. Wiegand, B. 18, 482).

**Properties.**—Trimetric plates (bysublimation) or monoclinic crystals (from water);  $a:b:c = 1:1.8065:1.5125$ ;  $\beta = 131^\circ$ . M. sol. hot ligroin.

**Reactions.**—1. *Potash-fusion* forms only acetic acid.—2. Not reduced to butyric acid by sodium amalgam (Körner, J. 1866, 818; A. 137, 233; cf. Bulk, A. 139, 62).—3. Br gives  $\alpha\beta$ -dibromo-butyric acid.—4. Conc. HBr at  $100^\circ$  gives  $\alpha$ - and a little  $\beta$ -bromo-butyric acid.—5. HOCl gives chloro-oxy-butyric acid.—6. Conc.  $\text{HNO}_3$  gives acetic and oxalic acids.—7. *Chromic acid mixture* gives aldehyde and acetic acid (Kekulé, A. 162, 315).—8. Aqueous ammonia forms  $\alpha$ -amido-butyric acid (Engel, C. R. 106, 1877).

**Salts.**— $\text{KA}'$ : deliquescent needles.— $\text{KHA}'_2$ : plates (from alcohol) (Pinner, B. 17, 2008).— $\text{NaA}'$ . S. (alcohol) 1.4 at  $14^\circ$ .— $\text{BA}'_2$ : easily soluble plates.— $\text{CaA}'_2$ : v. sol. cold, sl. sol. hot, water (Beilstein a. Wiegand, B. 18, 482).— $\text{PbA}'_2$ : stellate groups of needles.— $\text{ZnA}'_2$  2aq (Alberti, B. 9, 1194).— $\text{AgA}'$ : curdy pp.

**Methyl ether**  $\text{MeA}'$ . [121°]. S.G. 1.9806.  $\mu_D = 1.4138$  (Kahlbaum, B. 12, 344).

**Ethyl ether**  $\text{EtA}'$ . [139° cor.].  $\mu_D = 1.424$ .  $R_D$  50.45 (Brühl, A. 235, 8; B. 14, 2798). S.G. 1.9268;  $d_4^{25} = 0.9185$ . M.M. 7.589 at  $24.4^\circ$  (Perkin, C. J. 45, 537).

**Amide.** Syrup; v. sol. water (B. a. W.). A crystalline amide [c.  $151^\circ$ ] was obtained by Pinner (B. 17, 2008) by exposing to the air the hydrochloride of  $\beta$ -chloro-butyrimido-ether  $\text{CH}_2\text{CHCl}\cdot\text{CH}_2\cdot\text{C}(\text{OEt})\cdot\text{NH}\cdot\text{Cl}$ .

**Is-crotonic acid**  $\text{C}_8\text{H}_8\text{O}_4$ , i.e.

$\text{CH}_2\text{CH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  (?). *Quartenylic acid.* ( $172^\circ$  cor.). S.G. 1.018. Occurs in crude wood vinegar (Grodzki a. Krämer, B. 11, 1359).

**Preparation.**—Aceto-acetic ether is treated with  $\text{PCl}_5$  and the product poured into water. The two chloro-crotonic acids formed are distilled with steam. The chloro-iso-crotonic acid alone passes over. It is reduced by sodium amalgam, and the iso-crotonic acid is extracted by ether. On evaporation this leaves iso-crotonic acid as a syrup.

**Properties.**—Liquid, smelling like butyric acid; miscible with water. At  $175^\circ$  it changes to the preceding isomeride (Hemilian, A. 174, 322).

**Reactions.**—1. *Bromine* acting on a solution of iso-crotonic acid dissolved in  $\text{CS}_2$  produces the dibromide of ordinary solid crotonic acid (v.  $\alpha$ -bromo-butyric acid) (Kolbe, J. pr. [2] 25, 397).—2. *Potash-fusion* gives only acetic acid.—3. *Sodium amalgam* has no action.

**Salts.**— $\text{CaA}'$ , 2aq. very soluble needles.— $\text{BaA}'$ , 2aq. small crystals, v. e. sol. water.— $\text{PbA}'$ , 2aq. [68°].— $\text{AgA}'$ .

**Ethyl ether EtA.** (136°). S.G. 12.927 (Geuther, Z. 1871, 243).

**Isomeride of crotonic acid**  $\text{C}_4\text{H}_6\text{O}_2$ . [19°]. (181°). From vinacronic acid (*g.v.*) by distillation (Röder, A. 227, 24).

**Salts.**— $\text{CaA}'$ , 6aq.— $\text{BaA}'$ , 2aq.— $\text{AgA}'$ .

**Constitution.**—From its formation, from  $\text{CH}_2\text{:CH.CH}(\text{CO}_2\text{H})$ , it should be vinyl-acetic acid,  $\text{CH}_2\text{:CH.CH}_2\text{CO}_2\text{H}$ , a formula, attributed, without sufficient reason, to isocrotonic acid.

Another isomeride of crotonic acid v. METACRYLIC ACID.

**Dibromide of crotonic acid** v. DI-BROMO-BUTYRIC ACID.

**Derivatives of crotonic acid** v. BROMO-CROTONIC ACIDS and CHLORO-CROTONIC ACIDS.

**CROTONIC ALDEHYDE**  $\text{C}_4\text{H}_6\text{O}$  i.e.  $\text{CH}_3\text{CH:CHCHO}$ . Mol. w. 70. (105°). S.G. 1.033.

**Formation.**—1. By heating aldehyde with  $\text{ZnCl}_2$  and a little water to 100°, aldol being first formed:  $2\text{CH}_3\text{CHO} = \text{CH}_3\text{CH}(\text{OH})\text{CH}_2\text{CHO} = \text{CH}_3\text{CH:CHCHO} + \text{H}_2\text{O}$ . Other dehydrating agents may be used (Lieben, A. Suppl. 1, 117; Kekulé, Z. [2] 5, 572; A. 162, 92; Bauer, A. 117, 141; Lieben a. Zeisel, M. 1, 820). Hence it occurs in crude spirit (Krämer a. Pinner, B. 3, 75).—2. By the distillation of aldol (Wurtz, C. R. 87, 45).—3. From vinyl bromide by successive treatment with  $\text{H}_2\text{SO}_4$  and water (Zeisel, A. 191, 371).—4. From acetylene by successive treatment with  $\text{H}_2\text{SO}_4$  and water (Lagermarck a. Eltekoff, B. 10, 637).

**Preparation.**—Paraldehyde (1 pt.), water (1 pt.), and conc.  $\text{HClAq}$  (2 pts.) are kept at 25° for 5 days. The liquid is then neutralised with  $\text{Na}_2\text{CO}_3$ , the ppd. dialdane is filtered off, and the filtrate extracted with ether. The ethereal extract is distilled under reduced pressure, and the crude aldol ( $\frac{1}{2}$  pt.) (85° to 120° at 200 mm.) is split up into water and crotonic aldehyde ( $\frac{1}{2}$  pt.) by distillation under ordinary pressure (Newbury, C. R. 92, 196; Am. 5, 113).

**Properties.**—Pungent liquid; m. sol. water. Oxidised in the air or by  $\text{Ag}_2\text{O}$  to crotonic acid. It forms a crystalline combination with  $\text{NaHSO}_3$ , m. sol. water, whence  $\text{Na}_2\text{CO}_3$  does not liberate the aldehyde (Lieben a. Zeisel, M. 1, 818).

**Reactions.**—1.  $\text{PCl}_5$  gives di-chloro-butylene (126°).—2. By saturation with  $\text{HCl}$  in the cold it is converted into  $\beta$ -chloro-butylric aldehyde [97°].—3.  $\text{Br}$  gives oily  $\alpha\beta$ -di-bromo-butylric aldehyde (L. a. Z.).—4.  $\text{Cl}$  forms  $\alpha\beta$ -di-chloro-butylric aldehyde, and finally  $\alpha\beta$ -di-chloro-butylric chloride (Zeisel, M. 7, 353).—5. *Iron and acetic acid* reduces it to butyric aldehyde, butenyl alcohol, and *n*-butyl alcohol (L. a. Z.).—6.  $\text{Ac}_2\text{O}$  gives the di-acetyl derivative of crotonic orthoaldehyde  $\text{CH}_3\text{CH:CH.CH}(\text{OAc})_2$  (205°–210°). S.G. 1.05 (Lagermarck a. Eltekoff, J. R. 11, 79).—7. Dilute  $\text{HCl}$  at 0° forms, by hydration, a little aldol, paraldehyde, and dialdane (Wurtz, C. R. 97, 1169).—8. *Ammonia* forms tri-crotonylene-amine  $\text{C}_6\text{H}_{12}\text{N}_3$ . At –20° ammonia passed into an ethereal solution of the aldehyde forms  $\text{C}_6\text{H}_{12}\text{N}_3\text{O}$  (Combes, C. R. 96, 1862).—9. Crotonic aldehyde (1 pt.) treated with aldehyde (2 pts.) and  $\text{ZnCl}_2$  at 100° forms an aldehyde  $\text{C}_6\text{H}_8\text{O}$

(172°) Kekulé, A. 162, 105).—10. By heating with  $\text{HCN}$  and saponifying the product pentenoic acid  $\text{CH}_2\text{:CH.CH:CH.CO}_2\text{H}$  is formed (Lobry de Bruyn, Bl. [2] 42, 159).

**Derivative**  $\text{CH}_2\text{:CH.CH.CHCl}(\text{OEt})$  (134°). From di-chloro-butylene and alcoholic  $\text{KOH}$  (Kekulé, A. 162, 99).

**CROTONITRILE** v. ALLYL CYANIDE.

**CROTON OIL.** A fatty oil contained to the amount of 50 p.c. in the seeds of *Croton Tiglium*, a euphorbiaceous plant. It is purgative, and inflames the skin (Schlippe, A. 105, 1; Mayer, N. Jahr. pr. Pharm. 10, 318; Geuther a. Fröhlich, Z. [2] 6, 26, 549). It contains glycerides of formic, acetic, isobutyric, isovaleric (isobutylformic) and tiglic acids (E. Schmidt a. J. Berendes, A. 191, 94; B. 10, 835; Ar. Ph. [3] 13, 213). The nature of the purgative principle has not been satisfactorily made out (Senier, Ph. [3] 14, 446; Kobert, Chem. Zeit. 11, 416).

**CROTONYL ALCOHOL** v. BUTENYL ALCOHOL, vol. i. p. 639.

**CROTONYLENE** v. BUTINENE.

**TRI-CROTONYLENE-AMINE**  $\text{C}_{12}\text{H}_{18}\text{N}_3$ . (c. 190°) at 40 mm. Formed by heating aldol with excess of aqueous  $\text{NH}_3$  at 160°; or from crotonic aldehyde and  $\text{NH}_3$  at 100° (Wurtz, C. R. 88, 1154). Efflorescent prisms (containing 6aq); sl. sol. cold water, v. sol. alcohol.  $\text{HCl}$  at 150° resinifies it.

**Salts.**—Crystallise readily from acid solutions.— $\text{B}'3\text{HCl}$ : hexagonal prisms.— $\text{B}'\text{SHNO}_2$ : hexagonal prisms.— $\text{B}'\text{H}_2\text{Cl}_2(\text{PtCl}_6)_2$ .— $\text{B}'\text{H}_2\text{Cl}_2(\text{PtCl}_6)_2$ .— $\text{B}'\text{H}_2\text{Cl}_2\text{AuCl}_4$ .— $\text{B}'\text{H}_2\text{Cl}_2\text{AuCl}_4$ , 2aq.— $\text{B}'\text{H}_2\text{Cl}_2(\text{AuCl}_4)_2$ .

**CROTONYLENE GLYCOL** v. ERYTHRIT and DI-OXY-BUTYLENE.

**CROTYL ALCOHOL** v. BUTENYL ALCOHOL.

**CROTYLAMINE**  $\text{C}_4\text{H}_9\text{NH}_2$ . (75°–80°). Prepared by the action of alcoholic  $\text{NH}_3$  on isobutylene bromide. Liquid (Hofmann, B. 7, 514; 12, 992).—( $\text{D}'\text{HCl}$ )  $\text{PtCl}_4$ . Yellow scales.

**ISO-CROTYL BROMIDE** v. BROMO-BUTYLENE.

**ISO-CROTYL CHLORIDE** v. CHLORO-ISOBUTYLENE.

**CROTYL IODIDE** v. IODO-BUTYLENE.

**CROTYL THIOCARBIMIDE**  $\text{C}_4\text{H}_7\text{NCS}$ . (179°). From crotylamine (Hofmann, B. 7, 516). Pungent liquid.

**CROTYL-THIO-UREA**  $\text{C}_4\text{H}_7\text{NHCSNH}_2$ . [85°]. From the preceding and  $\text{NH}_3(\text{H})$ . Crystalline.

**CRYPTIDINE**  $\text{C}_{11}\text{H}_{11}\text{N}$ . (274°). A homologue of quinoline occurring in coal tar (Greville Williams, Chem. Gaz. 1856, 283).

**Cryptidine**  $\text{C}_{11}\text{H}_{11}\text{N}$ . (270°). Prepared by the dry distillation of xylidine-acrolein (Leeds, A. C. J. 5, 2). Reddish-yellow oil. Disagreeable odour. Bitter taste.— $\text{B}'\text{HCl}$ : fine thin tabular crystals.— $\text{B}'\text{H}_2\text{PtCl}_6$ : fine yellow crystals. Sol. water, insol. alcohol.

**CRYPTOPHANIC ACID**  $\text{C}_8\text{H}_6\text{NO}_4$ . An acid said to occur in normal human urine (Thudichum, C. J. 23, 116; 34, 81). The urine is evaporated to one-fourth of its bulk and  $\text{Fe}_2\text{Cl}_6$  added. The pp. contains the iron salts of cryptophanic, paraphanic, hippuric, and benzoic acids. It may be decomposed by baryta. Amorphous gum, v. e. sol. water.— $\text{PbA}'$ .— $\text{CaA}'$ .

**CRYPTOPINE**  $\text{C}_8\text{H}_6\text{NO}_4$ . [217°]. S. (alcohol) 0.8 (Smith). S.G. 1.35 (Schröder B. 18,

1075). A base occurring in very small quantity in opium (T. a. H. Smith, *Ph.* [2] 8, 595, 716; Hesse, *A. Suppl.* 8, 209; A. 176, 200; Kauder, *Ph.* [3] 18, 250). Ppd. by adding NaOH to the mother-liquor, from which codeine, narceine, thebaine, and papaverine have been separated. Six-sided prisms (from alcohol); when freshly ppd. it is soluble in ether, but it slowly separates from the solution. Sl. sol. boiling alcohol, v. sl. sol. benzene and ligroin, m. sol. chloroform. Dissolves in excess of KOHAq. Inactive to light. Conc. (impure)  $H_2SO_4$  gives a blue colour turned orange by  $KNO_3$ .  $FeCl_3$  gives no colour. Not decomposed by HCl.

**Salts.**—Separate from aqueous solution as jellies, but subsequently become crystalline.—B'HCl 6aq: soft mass of crystals (from alcohol).—B'HCl 5aq.— $B_2H_4PtCl_6$  6aq.— $B_2H_4Cr_2O_7$ .— $B_2H_4C_2O_6$ . S. 3 at  $12^\circ$ .— $B_2C_2H_4O_4$  4aq. S. 15 at  $10^\circ$ .— $B_2C_2H_4(NO_3)_2$  OH aq.

Meconate  $B_2C_2H_4O_4$  10aq: sl. sol. boiling water.

**Nitro-cryptopine**  $C_{21}H_{29}(NO_2)_2NO_2$ . [ $185^\circ$ ]. From cryptopine and  $HNO_3$  (S.G. 1.06) at  $55^\circ$ . Dark-yellow crystalline powder. Insol. water and KOHAq. Conc.  $H_2SO_4$  dissolves it with blood-red colour.—B'HCl 8aq.— $B_2H_4PtCl_6$  10aq.—B' $HNO_3$ .—Oxalates  $B_2H_4C_2O_6$  12aq. S. 6.8 at  $16^\circ$  and  $B_2H_4C_2O_6$  3aq.

#### CRYSTALLIN v. PROTEIDS.

**CRYSTALLISATION.**—The examination of a crystal and the determination of its form and properties may serve as a means of recognising and defining any given body. But besides this practical application, the examination may help to find an answer to the question: What is the connexion between the chemical constitution and the crystalline form of bodies?

The complete examination of the form and properties of a crystalline substance may demand a thorough knowledge of crystallography, and also skill in the use of complicated and costly instruments; but a general knowledge of the principles of the subject, and of the use of a geological microscope, such as ought to be found in every laboratory, will very often enable the chemist approximately to determine the form of a substance, the identity or non-identity of two samples, or the homogeneous character of his preparations. The following account may serve as a general view of the subject, or as an introduction to a more complete study; it is necessarily incomplete, and for further details special books must be consulted, such as Groth's *Physikalische Kristallographie*; current literature being found in the *Zeitschrift für Kristallographie*, and the different mineralogical journals.

A crystal may be described as a solid homogeneous body bounded by plane faces that are arranged around the body in a certain regular manner, which is constant for each chemical compound. Neither the number of faces that bound a crystal, nor the shapes of these faces, are constant and characteristic, since both may vary considerably with very slight alterations of external conditions at the time of crystallisation; but the regularity, or the symmetry which all the faces bear to each other, and the manner in which the faces occur in

groups or sets or 'forms,' is constant and characteristic.

**Single or Simple crystalline form.**—That all the faces of a crystal do not belong to the same form is often strikingly evident by a difference in colour, as in many of the platinocyanides, or in the condition of the faces, some of which are smooth and lustrous, while others are dull or streaked with numerous fine lines, or are rough with little pittings, or appear to be made up of numerous scales, and then show a pearly lustre; such differences are to be noticed on crystals of magnesium sulphate, quartz, salt, alum, potassium ferrocyanide, potassium chlorate, gypsum, copper sulphate, &c. The same fact is often also to be noticed in another way, viz. by the appearance of splits or cleavage planes that run parallel to certain faces but not to others, as in calcite and potassium ferrocyanide; often where such are not manifest the crystal may be easily split or cleaved parallel to certain faces but not to others, as with gypsum, cane sugar, magnesium sulphate, &c. Differences in the forms of the faces of crystals are often shown by the way in which the crystal during its growth has inclosed foreign substances, as bubbles of liquid or gas, or fragments of solid substances that were suspended in the solution, viz. the inclosures are distributed in lines or planes parallel to certain edges or planes of the crystal, but not to others. In examining a crystal all such observations are of the greatest service, as they at once give a means of classifying the may-be numerous faces into their proper sets or forms.

A crystal may be completely bounded by only one set of faces, e.g. a cube of rock salt; but there are several crystalline forms that are not capable of inclosing space, as the various prisms and pinacoids, or basal planes, and such forms necessarily never occur alone. The minimum number of crystalline forms that may occur on a crystal is limited only by the condition that they must completely inclose the crystal; the maximum number is unlimited; but however many there may be, all are correlated by an empirical law, known as the *rationality of indices*, and the symmetry of faces constituting each individual form is the same.

This last statement, though strictly true, is apparently not so in several cases, as certain forms show externally a geometrical symmetry apparently other than that which belongs to their internal structure; thus both salt and iron pyrites crystals often exhibit no other form than the cube, and therefore are apparently possessed of the same kind and amount of symmetry, yet other forms that occur in these two substances show that iron pyrites is really possessed of a lower degree of symmetry than sodium chloride (v. *Hemihedral forms*, p. 283).

**Symmetry of crystalline forms.**—A solid figure may be symmetrical about a point, or about a plane, or a number of planes. A solid figure is *symmetrical about a point* when any number of particles on the surface being joined to the central point by straight lines, these being produced to equal distances on the other side of the centre shall exactly coincide with a series of similar particles. This kind of symmetry only demands that to every face there

be a second and parallel one; it is only met with in the asymmetric (*i.e.* without symmetry) crystals, as, for instance, copper sulphate and potassium anhydrochromate.

A solid figure is *symmetrical about a plane* when from any number of particles on the surface perpendiculars being drawn to the plane and produced equal distances on the other side of the plane, the points so found shall exactly coincide with a series of similar particles; in other words, the one half is the mirrored image of the other, the mirror being the *plane of symmetry*. Thus a cube is symmetrical about the plane  $acge$ . A line perpendicular to the plane of symmetry is called an *axis of symmetry*, and about a central point in this axis the figure is also symmetrical. Thus (fig. 1), starting with  $acge$  as a plane of symmetry, and  $abfe$  as any given plane, the existence of  $adhe$  and  $dcgh$  necessarily follows, as the former is the image mirrored in the plane of symmetry, and the latter is the plane symmetrical to the first with regard to the central point; the existence of  $bcgf$  follows similarly from either or both of the last two faces.

FIG. 1.

Besides the above-mentioned plane  $acge$  there are five others that divide the cube in exactly the same fashion, viz. the planes  $bdlf$ ,  $bahg$ ,  $cfdh$ ,  $afgd$ , and  $befc$ , and these make therefore a set of six planes of symmetry; and the corresponding six axes of symmetry are the lines  $mn$ ,  $op$ ,  $qr$ ,  $st$ ,  $uv$ , and  $wx$ , joining the centres of the opposite edges (fig. 2).

A plane that is at right angles to two planes of symmetry contains two axes of symmetry, and

FIG. 2.

must therefore itself be a plane of symmetry; and if, as in the case now considered, the two contained axes of symmetry are similar, then the symmetry of the new plane is of a higher order than that of the two others. The above six planes may be taken two at a time in three different ways, and thus a set of three new planes of a higher order are found; they are called *planes of principal symmetry* as distinguished from *planes of ordinary symmetry*; they are  $qrst$ ,  $wuvx$ , and  $ompn$  (fig. 2), and the corresponding axes of principal sym-

metry are the lines  $AB$ ,  $CD$ , and  $EF$  (fig. 3). As a plane of principal symmetry contains two, and in the hexagonal system three, exactly similar axes of symmetry, the appearance and

FIG. 3.

actual position of a crystal is not changed by rotating it about the axis of principal symmetry such that first one and then another of the similar axes of ordinary symmetry come to occupy the same position. In this way a plane of principal symmetry may be most readily distinguished from a plane of ordinary symmetry.

*Division of crystals into classes.*—A crystal can only be possessed of a set of three exactly similar axes of principal symmetry, or of one such axis, or it must be devoid of any such; and all crystals may accordingly be divided into three great classes: (1) Crystals possessed of three axes of principal symmetry must necessarily contain also a set of six axes of ordinary symmetry (as explained above in the case of the cube), and all such are said to belong to the *Regular system*. (2) Crystals possessing one axis of principal symmetry must necessarily contain axes of ordinary symmetry at right angles to the first. The number of these axes of ordinary symmetry may be either (1) a set of three inclined to each other at one-third of four right angles, with, as a necessary consequence, a second set of three, also inclined to each other at one-third of four right angles, but removed from the first set by one-sixth of four right angles, or (2) a set of two at right angles to each other, with, as a necessary consequence, a second set of two also at right angles to each other, but removed from the first set by half a right angle. Crystals satisfying the first set of conditions are said to belong to the *Hexagonal system*, and those satisfying the second set to the *Quadratic system*. (3) Crystals destitute of any axis of principal symmetry may yet contain axes of ordinary symmetry, and the possible cases are (i) three sets of one axis each, *i.e.* three dissimilar axes, which must of necessity be at right angles to each other, (ii) one single axis, and (iii) no axis of symmetry at all. Crystals satisfying these three conditions are said to belong to the *Rhombic system*, to the *Monosymmetric* (formerly called the monoclinic) system, and to the *Asymmetric* (formerly called the triclinic) system.

Thus all crystals may be divided geometrically into the above six systems; and it is a very important fact that exactly the same division is effected by a consideration of all the physical properties, more especially the optical and mechanical ones, viz. tensional strength, the thermal and electrical properties being difficult of investigation, and also by a mathematical discussion of the possible ways of arranging a number of points in space. Crystals of the

regular system behave optically like amorphous bodies, they are singly refractive and are therefore said to be *isotropic*. All other crystals are doubly refractive and are called *anisotropic*; they are divided into two classes according as they contain one direction or no direction along which a beam of light may travel and then emerge from the crystal without suffering double refraction; those possessed of this axis of single refraction are termed *optically uniaxial*. The hexagonal and quadratic crystals are both uniaxial, and optically they are undistinguishable; in both cases the tensional strength in the plane of principal symmetry varies with the direction in which it is determined, but while hexagonal crystals show three directions of minimum and of maximum strength, quadratic crystals show only two. Anisotropic crystals that are not uniaxial have been called *optically biaxial*, though they have not two directions that are truly void of the power of doubly refracting light as above defined. When a properly-cut section of a biaxial crystal is examined in 'convergent polarised light' the two optical axes are seen surrounded by dark and light rings gradually shading into each other, and as the 'interference figure' is not the same for light of any two colours, so the rings, merging more or less completely into each other, are fringed with colour, and by a careful examination of the coloured fringes it can be determined to which of the last three systems the crystal belongs; viz. if rhombic, the figure is symmetrical about both diameters AB and CD, and consequently also about the central point E; if monosymmetric, the figure is symmetrical about one or other of the diameters or about the central point, according to circumstances; if a-symmetric, the figure is void of symmetry (fig. 4).

FIG. 4 (diagrammatic).

In studying the geometrical properties of crystals, certain lines must be taken within the crystal, to which all the faces may be referred; these lines, of which there must be three, are called the *crystallographical axes*, and they are represented by the letters *a, b, c*, while the inclinations which they make with each other are represented where necessary by the letters  $\alpha, \beta, \gamma$ , viz.  $\alpha: b = \gamma$ ;  $\alpha: c = \beta$ ; and  $b: c = \alpha$ . In each system the crystallographic axes are chosen in such a way that the different forms may be most simply expressed. By this is to be understood that each of the different faces that together

make a single crystalline form is to be related to the axes in exactly the same numerical way, or in other words the geometrical symbol for each of the faces of a form is exactly the same if the signs be omitted that denote a face to be at the top, front, right hand, &c. In the regular system the three axes of principal symmetry are chosen, and as these are all exactly similar and equal, the expression *a, b, c* becomes *a, a, a*, and as '*a*' stands thus alone it may itself be considered as unity, and the axial expression thus becomes  $a = a = a = 1$  or  $a = 1$ ; the expression for the axial angles is always  $\alpha = \beta = \gamma = 90^\circ$ . In the hexagonal system one set of three axes of ordinary symmetry (two of these three axes would be sufficient, but for the sake of completeness it is convenient to include the third, this is also not without its advantages), and the axis of principal symmetry, are chosen; as the first three are exactly alike, but are independent of the last, the expression for the axes *a, b, c* becomes *a, a, a, c*; one of these may be made equal to unity, most conveniently *a*, and the crystallographical axes are expressed  $a:c = 1:c$ . The axial angles are in all cases  $a:c = 90^\circ$  and  $a:a = 120^\circ$ . Here notice that any and every crystal of the regular system has its axes represented by  $a = b = c = 1$  and  $\alpha = \beta = \gamma = 90^\circ$ , and these facts do not therefore need to be repeatedly stated, for they are comprehended in the expression 'regular system.' The same holds good with the axial angles of any and every hexagonal crystal, viz.  $a:a:a = 120^\circ$  and  $a:c = 90^\circ$ ; but with the relative lengths of the axes it is otherwise, the ratio of *a:c* is not the same for any two substances, and in describing a hexagonal crystal the *crystallographical constant*, the *axial ratio a:c*, must be accurately measured and given; thus for example in lead dithionate it is as 1:1.5160, while in strontium dithionate, which has almost exactly the same form and is therefore said to be *isomorphous*, it is as 1:1.5024.

These crystallographical axes are not to be considered as definite lines, having definite lengths, but as directions, determined by the symmetry of the crystal, and consequently endowed with certain properties—viz. like axes must be cut by the like number of faces at the like angles—and upon which the relative lengths of the intercepts cut off by the various faces may be calculated trigonometrically from the measurements of the interfacial angles. These angles are always measured by means of a reflecting goniometer, above the centre of whose graduated circle the edge, over which the angle is to be measured, is exactly placed by means of adjusting screws. About the same centre the crystal and a collimator or telescope may be made to revolve; the position of a beam of light incident upon the crystal, and the positions of the reflected beams from the two lustrous crystal faces, are thus measured, and the interfacial angle determined. The method of calculation may be exemplified by reference to a beryl crystal. Here there are four sets of faces, each of which, of course, cuts the axes differently, and one of these manners of cutting must be chosen as the standard (fig. 5). The basal faces (0001) cut only the vertical axis, the prismatic faces (1010) cut only the hori-

horizontal axes, and hence neither of these forms alone allows a determination of the ratio  $a:c$ .

FIG. 5.

But the faces of each of the two pyramids (1011) and (2111) cut both horizontal and vertical axes; for the sake of simplicity the faces (1011) are chosen as those of the primary pyramid, and the three horizontal axes are thus fixed as being parallel to  $AA'$ ,  $BB'$  and  $CC'$ . The angle 1011:0001 having been measured and found

FIG. 6.

$150^\circ 3' 20''$ ,  $a:c$  is easily calculated thus;

$\tan (180^\circ - 150^\circ 3' 20'') = \frac{oc}{on}$ , but if  $oa = \text{unity}$ , then

$on = \frac{\sqrt{3}}{2}$ , hence  $oc = \frac{\sqrt{3}}{2} \tan (180^\circ - 150^\circ 3' 20'')$   
 $= 0.4989$ ; that is,  $a:c = 1:0.4989$  (see fig. 6).

If, however, the angle of the pyramid over a terminal edge, i.e. (1011):(0111) had been measured and found equal to  $151^\circ 5' 40''$ , then by describing from the point  $a$  a spherical triangle cutting the face of the crystal in  $AB$  (fig. 7), the plane of principal symmetry in  $AC$ ,

FIG. 7.

and the plane of ordinary symmetry in  $CB$ , the side  $a$  can be found from the known data,  $B = \frac{1}{2}(151^\circ 5' 40'')$ ,  $b = 60^\circ$ , and  $C = 90^\circ$ ;

thus  $\sin c = \frac{\sin b}{\sin B}$ , hence  $c = 63^\circ 25' 20''$ ,

then  $\tan \frac{1}{2}a = \tan \frac{1}{2}(c-b) \frac{\sin \frac{1}{2}(B+C)}{\sin \frac{1}{2}(C-B)}$   
 $= \frac{\tan 1^\circ 42' 40'' \times \sin 82^\circ 46' 25''}{\sin 7^\circ 13' 35''}$ ;

hence  $\frac{1}{2}a = 18^\circ 15' 25''$ , and  $a = 26^\circ 30' 50''$ ;

and lastly  $\frac{\text{axis } c}{\text{axis } a} = \tan 26^\circ 30' 50''$ , from which the value for the vertical axis  $c = 0.4989$  is again found.

For any given crystal the axial ratios are

thus exactly determinable, but where any arbitrary choice has been made, as in this instance, then the same is adopted by all subsequent observers unless good reasons are found for making an alteration.

In the quadratic system one of the two sets of two axes of ordinary symmetry, and the axis of principal symmetry, are chosen; the axial angles are in all cases  $90^\circ$ ; the expression  $a, b, c$ , thus becomes  $a, a, c$ , and, as in the hexagonal system, the axial ratio  $a:c$  has to be actually determined in every individual case. In the rhombic system the three axes of ordinary symmetry are chosen; the axial angles are in all cases  $90^\circ$ ; as these three axes are not similar, the expression  $a, b, c$ , remains as such; making one equal to unity, the other two constants have to be determined in every individual case. In the monosymmetric system the axis of symmetry is chosen as one crystallographical axis; the other two axes must lie in the plane of symmetry, but otherwise their positions are perfectly arbitrary; for simplicity's sake, they are chosen parallel to two well-defined edges or faces on the crystal; in this system  $a, b, c$ , are quite independent and have to be determined,  $b$  is generally the axis of symmetry and is made equal to unity; the inclinations of  $b:a$  and  $b:c$  are in all cases  $90^\circ$ , but the inclination of  $a:c$  (axial angle  $\beta$ ) is variable and must be determined. In the asymmetric system the crystallographic axes are chosen quite arbitrarily; generally however they are chosen parallel to three prominent edges of the crystal; they are quite independent of each other, therefore of unequal lengths, and moreover no two of them are inclined at right angles to each other; for asymmetric crystals there are thus five constants to be determined.

*Relation of faces to axes. Rationality of indices.*—When a number of sets of faces on a crystal are referred to the axes whose relative lengths have been found as just explained, it is noticed that the intercepts cut off can in all cases be expressed as some simple multiple or sub-multiple of the fundamental axial lengths. This is known as the *rationality of the indices*. Thus in the case of the beryl crystal (fig. 5), while the faces of the primary pyramid cut the axes  $a:a:c$  at the distances  $1:a:1:0.4989$ , those of the faces (2111) cut at  $1:2:2:0.9978$ ; here 1 is  $1 \times 1$ , 2 is  $2 \times 1$ , and  $0.9978$  is  $2 \times 0.4989$ , and the numbers 1, 2, 2, 2 are here indices. The indices are generally expressed by very simple numbers, as 1, 2, 3, 4, 5, 6,  $\frac{1}{2}$ ,  $\frac{3}{4}$ ,  $\frac{5}{6}$ , &c., but in some cases the ratios are not so simple.

The indices of a face may be measured in two ways—the one known as Neumann's system, and the other as Miller's. Let the relative lengths of any set of primary axes be expressed by the letters  $a, b, c$ , and let there be another face on the crystal which cuts the axes at some other distances, say  $2a, 3b, 4c$ , from their centre. According to Neumann the indices of this face are  $\frac{2a}{a}, \frac{3b}{b}, \frac{4c}{c}$  i.e. 2, 3, 4; following Miller,

however, the indices are the reciprocals of those of Neumann, viz.  $\frac{a}{2a}, \frac{b}{3b}, \frac{c}{4c}$ , i.e.  $\frac{1}{2}, \frac{1}{3}, \frac{1}{4}$ ,

or, simplifying, the expression becomes 6, 4, 3.

Of course there will be more than one face having this symbol, the number depending on the symmetry of the crystal, but the relative positions of any of these may be exactly denoted by the following device. In all the systems the extremities of the axes forming the front upper right corner are called positive, and are simply written  $a, b, c$ , &c., while the opposite extremities are called negative, and are written  $\bar{a}, \bar{b}, \bar{c}$ , &c. Thus taking the pyramid of the beryl crystal, and using Miller's symbols, we have the axes and faces numbered as in figs. 8 and 9.

FIG. 8.

FIG. 9.

The axial ratios once determined, it is possible from them and the symmetry to say at once what forms are possible, and to calculate their interfacial angles, &c.; but what forms will actually occur, under any conditions, cannot be predicted; their existence depends on external conditions, as presence of impurities in the solution, nature of the solvent, temperature, and speed of growth. Mineralogists and crystallographers often pay too much attention to the finding of new or numerous forms upon specimens without attempting to determine what were the conditions necessary for the production of these forms, which is the only point of real interest.

The following may serve as an example of the way in which the symmetry of a crystal determines the number and position of the faces of a form. In fig. 10 the three similar crystal-

FIG. 10.

lographic axes of the beryl crystal (fig. 5) are represented by the lines  $a_1, a_2$ , and  $a_3$ , while the principal axis  $c$  is perpendicular to the plane of the paper. Suppose a face of the hexagonal pyramid to be present in the front, upper, middle segment, i.e.  $1011$ , then this demands the existence of a face  $1101$ , because the plane passing through axis  $a_1$  and the vertical axis  $c$  is a plane of symmetry; the presence of  $1101$  demands the existence of  $0111$ , because the plane containing  $a_2$  and  $c$  is a plane of symmetry; further, these three faces demand the existence of other three, viz.  $0111, 1101, 1011$ , because the plane  $a_3c$  is a plane of symmetry; and lastly, these six planes demand the presence of other six on the under part of the crystal, viz.  $1011, 0111, 1101, 1011, 0111, 1101$ , because the plane containing axes  $a_1, a_2, a_3$  is a plane of symmetry. And with these twelve faces the form is complete, for the

other three planes of symmetry belonging to this system are already satisfied.

It would be very tedious and redundant to denote this or any other form by writing the symbols of all its faces, and it is therefore customary to write the symbols of only one, generally one in the front, upper, right corner, and to inclose it in brackets thus  $(1011)$  for the pyramid in question. The general shape of a form is not essentially altered by varying the indices within certain limits; thus  $(3031)$  and  $(1013)$  (figs. 11 and 12) as well as  $(1011)$  (fig. 9),

FIG. 11.

represent hexagonal pyramids, though the form  $(3031)$  is very high and pointed, while the form  $(1013)$  is proportionally low and flat-looking. These may all be expressed by one general

FIG. 12.

symbol  $(m0\bar{m}1)$  (where  $m$  has any value between 0 and  $\infty$ ), and are said to be particular forms of one general form  $(m0\bar{m}1)$ ; thus fig. 12 represents the particular form for a crystal of beryl when  $m = \frac{1}{2}$ , for  $1013$  is the same as  $\frac{1}{2}0\bar{1}3$ , i.e.  $m0\bar{m}1$ .

But if the index  $m$  has the value of 0, then the six upper faces of the pyramid fall together into one plane, and so also do the six lower faces, so that the form  $(0001)$  consists only of two faces parallel to each other and also to the plane of principal symmetry; if  $m$  has the value of  $\infty$ , then each of the upper six faces becomes coincident with the subjacent bottom face, and the form  $(\infty 0\bar{\infty} 1)$ , or, as it is more usually written,  $(1010)$ , consists of six faces, all parallel to the axis of principal symmetry, and consequently not limited towards either end; these two forms  $(0001)$  the basal plane, and  $(1010)$  the prism, may be called open forms, and can never occur alone on a crystal. They contain no variable quantity, and may therefore be called *fixed forms*, while the pyramid is a *variable form*.

These two forms, the basal plane and the prism, though derivable from the pyramid and related to it in position, are obviously quite distinct forms, and all are so far independent of each other that any one may or may not occur on a crystal in conjunction with the others. By varying the indices in every possible manner, as just indicated, it is easy to determine the shapes

and number of all such fundamental or general forms for every system; and indeed it is only possible to grasp the relationships existing between them by regarding them as being derived from one perfectly general form ( $mn1$ ). The number of individual forms is very limited; the following is a complete list of their symbols and names.

**Regular system.**—( $mn1$ ), ( $mm1$ ), ( $mn0$ ), ( $mm0$ ), ( $111$ ), ( $001$ ), ( $110$ ), called respectively *hexakis octahedron*, *trikakis octahedron*, *tetrakis hexahedron*, *trapezohedron*, *octahedron*, *cube* or *hexahedron*, and *dodecahedron*; the last three are fixed forms.

**Hexagonal system.**—( $m\bar{p}n1$ ). (Note: in the symbols for all hexagonal forms  $m+n+p=0$ ).

$m\bar{p}n0$ , in both these cases the ratio  $\frac{m}{n}$  varies only between 1 and 2; ( $m0\bar{m}1$ ), ( $10\bar{1}0$ ), ( $2m\bar{m}n1$ ), ( $21\bar{1}0$ ), and ( $0001$ ), called respectively the *hexagonal pyramid* and *prism*, the *hexagonal pyramids* and *prisms* of the first order, and of the second order, and the *basal plane*.

**Quadratic system.**—( $mn1$ ) and ( $mn0$ ), where the ratio  $\frac{m}{n}$  varies between 1 and  $\infty$ ; ( $mm1$ ), ( $mm0$ ), ( $m01$ ), ( $m00$ ), and  $001$ ; the forms are called the *diquadratic pyramid* and *prism*, the *quadratic pyramid* and *prisms* of the first order, and of the second order, and the *basal plane*.

**Rhombic system.**—( $mn1$ ), ( $mn0$ ), ( $001$ ), called respectively *pyramidal prisms* or *domes*, and *basal plane* or *pinacoids*.

**Monoclinic system.**—The same forms exist as in the rhombic system, but here, owing to low order of symmetry, all the pyramids and some of the domes are composed of independent halves, which are distinguished as + or −, or by more fully denoting the position of the face; thus ( $mn1$ ) and ( $m\bar{n}1$ ).

**Asymmetric system.**—The same forms exist as in the rhombic system, but here, owing to the lack of symmetry, all the pyramids are composed of independent quarters, thus ( $mn1$ ), ( $m\bar{n}1$ ), ( $mn1$ ), and ( $m\bar{n}1$ ), and all the prisms and domes are composed of independent halves, thus ( $mn0$ ) and ( $m\bar{n}0$ ).

The forms just described are collectively called *holohedral* or whole or complete-faced forms, to distinguish them from other forms known as *hemihedral* or half-faced, and *tetartohedral* or quarter-faced.

**Hemihedral forms** may be considered as derived from the holohedral forms by resolving these by a set or sets of planes of symmetry into a number of equal segments, when the faces contained in any one segment belong to the one hemihedral form, while those contained in the adjacent segment or segments belong to the other hemihedral form, and so on all round the crystal.

The hemihedral forms of the hexagonal system being very important will be taken by way of example. Any holohedral hexagonal form may be divided into segments in three different ways:—

*Firstly*, by the plane of principal symmetry and one of the two sets of three planes of ordinary symmetry; making then the adjacent

faces independent, the *rhombohedral hemihedral* forms are produced. Numbering the faces of the most general form, the dihexagonal prism, as in fig. 13 it is seen that the faces are divided thus:

1	2	3	4	5	6	7	8	9	10	11	12
$\bar{1}$	$\bar{2}$	$\bar{3}$	$\bar{4}$	$\bar{5}$	$\bar{6}$	$\bar{7}$	$\bar{8}$	$\bar{9}$	$\bar{10}$	$\bar{11}$	$\bar{12}$

FIG. 13.

The two forms

1	2	3	4	5	6	7	8	9	10	11	12
$\bar{1}$	$\bar{2}$	$\bar{3}$	$\bar{4}$	$\bar{5}$	$\bar{6}$	$\bar{7}$	$\bar{8}$	$\bar{9}$	$\bar{10}$	$\bar{11}$	$\bar{12}$

and

1	2	3	4	5	6	7	8	9	10	11	12
$\bar{1}$	$\bar{2}$	$\bar{3}$	$\bar{4}$	$\bar{5}$	$\bar{6}$	$\bar{7}$	$\bar{8}$	$\bar{9}$	$\bar{10}$	$\bar{11}$	$\bar{12}$

are known as the + and − *scalenohedrons* (figs. 14 and 15), which differ from each other in posi-

FIG. 14.

FIG. 15.

tion and in physical properties. Just as in the holohedral division, so here, the indices of only one face is written within brackets to denote the whole form, but to distinguish it from the symbol of the original pyramid the prefix  $\kappa$  is added; thus the symbols for the two scalenohedrons are  $\kappa(m\bar{p}n1)$  and  $\kappa(pn\bar{m}1)$ . By varying the values of these indices  $m, n, p$  in every possible way, or by dividing all the other holohedral forms into segments in the same fashion, it is found that there are produced two other new forms, the + and − *rhombohedrons*  $\kappa(m0\bar{m}1)$  and  $\kappa(0m\bar{m}1)$ , figs. 16 and 17; while the following forms already mentioned in the holohedral division appear again without apparent alteration, viz. ( $m\bar{p}n0$ ), ( $10\bar{1}0$ ), ( $2m\bar{m}n1$ ), ( $21\bar{1}0$ ), and ( $0001$ ). But the con-

stancy of these latter forms in both divisions is not real, as the physical properties are different; this is especially to be seen in the manner in which they yield to the action of solvents, whereby little pittings or *etch-figures* are produced which vary in their symmetry according as the forms are holohedral or hemihedral. It

FIG. 16.

is to be understood that practically the holohedral and hemihedral forms are perfectly distinct, that is, a given substance shows the forms of only one of the two classes, never those of the other. For example, calcite frequently occurs in the form of the scalenohedron (3i21), fig. 14, and is therefore obviously hemimorphous, but it also frequently occurs in the form of fig. 18, and

FIG. 17.

FIG. 18.

this may be either a holohedral or a hemihedral crystal, but the fact that such crystals cleave with the utmost readiness parallel to the faces of the positive rhombohedron  $\kappa(m0\bar{m}1)$  at once removes it from the class of holohedral crystals; its hemimorphous nature is also proved by other physical properties.

A holohedral hexagonal form may be divided into segments, *secondly*, by means of the two sets of three planes of ordinary symmetry, whereby the *pyramidal hemihedral forms* are produced; for example:—

$$\begin{array}{cccccccccccc} \pm & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\ \pm & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \end{array}$$

The uncrossed faces  $\pi(pn\bar{m}1)$  are represented on a crystal of apatite by figure 19 where  $\pi(pn\bar{m}1) = \pi(21\bar{3}1)$ . All other forms are exter-

FIG. 19.

nally the same as in the holohedral division, with the exception of  $\pi(pn\bar{m}0)$ . These two new forms are called the *pyramid* and *prism* of the third order.

*Thirdly*, by means of the two sets of three planes of ordinary symmetry and the plane of

principal symmetry, whereby the *trapezohedral hemihedral forms* are produced; for example:—

$$\begin{array}{cccccccccccc} \pm & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\ \pm & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \end{array}$$

These forms are distinguished by the prefix  $\tau$ , the crossed faces being  $\tau(m\bar{p}n1)$ ; such forms have not been actually observed.

The *tetartohedral forms* before referred to may be considered as being produced by the superposition of two different hemihedra upon the same crystal. As there are in the hexagonal system three classes of hemihedra, there can be obtained two or perhaps three different classes of tetartohedra. In the following schemes the faces suppressed by the rhombohedral, pyramidal, and trapezohedral, hemihedra are respectively crossed  $\diagup$ ,  $\diagdown$ , or  $\diagup$ .

First, the *rhombohedral tetartohedra* is produced thus:—

$$\begin{array}{cccccccccccc} \diagup & 2 & 3 & 4 & \diagdown & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\ \diagdown & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \end{array}$$

The faces of a dihexagonal pyramid remaining uncrossed, viz.  $\pm 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12$ , form a rhombohedron of the third order, written  $\kappa\tau(m\bar{n}p1)$ , which is exhibited in fig. 20 of a copper silicate (diaspore) crystal, where the indices are  $\kappa\tau(14.13.1.6)$ .

FIG. 20.

FIG. 21.

*Secondly*, the *trapezohedral tetartohedra* is produced thus:—

$$\begin{array}{cccccccccccc} \diagup & 2 & 3 & \diagdown & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\ \diagdown & 2 & 3 & 4 & \diagup & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \end{array}$$

the form  $\kappa\tau(np\bar{m}1)$  consisting of the six uncrossed faces  $\pm 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12$ , being known as the trigonal trapezohedron, and in the figure representing a quartz crystal the faces of such a form, viz.  $\kappa\tau(5161)$  are shown (fig. 21).

*Thirdly*, the scheme

$$\begin{array}{cccccccccccc} \pm & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\ \pm & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \end{array}$$

shows a form bounded by six faces meeting the vertical axis above, but no face meeting it below. It is doubtful whether this tetartohedra has been observed; for exactly the same form would be produced by making either of the form  $\pi(m\bar{n}p1)$  or  $\tau(m\bar{p}n1)$  hemimorphous or half-sided.

*Hemimorphism* may be described as the dividing of the faces of a crystalline form into two independent halves, the one half cutting the other extremity of an axis of symmetry, and the other half the other extremity of the same axis. Hemimorphism is to be found in the first five systems

holohedral, hemihedral, and tetartohedral, divisions alike; it is supposed to be due to asymmetry of the atoms in the molecule, and the solutions of the substances showing this phenomenon, as tartaric acid, milk, sugar, &c., are generally optically active. It is to be noticed that some divisions of crystals are necessarily hemimorphous. Thus the hexagonal trapezohedral tetartohedral forms are hemimorphous to the axes of ordinary symmetry.

The hexagonal crystals are thus divided into the following six or seven distinct classes: (a) holohedral; (b) hemihedral, and that of three kinds, rhombohedral, pyramidal, and trapezohedral; and (c) tetartohedral, and that of at least two kinds, rhombohedral and trapezohedral, and possibly another; and lastly to each of these six classes there may or may not be assimilated also hemimorphism, making in all twelve or possibly thirteen divisions of hexagonal crystals, in only one of which can any substance ever crystallise.

These six or seven classes are to be considered as being due to the different arrangements of the molecules in the crystal, but among these different molecular arrangements there are certain regularities common which group them all together into one general system. It is to be noted that all hemihedral and tetartohedral divisions are invariably possessed of fewer planes of symmetry or of planes of a lower degree of symmetry than are the holohedral forms; thus the trapezohedral hemihedral forms and all tetartohedral forms of the hexagonal system are possessed of no plane of symmetry whatever, *i.e.* as defined at the commencement of this article; but such forms do not, therefore, belong to the asymmetric system, for in the first place they show a perfect regularity in the recurrence of equal faces and angles in sets of three or of six, which an asymmetric crystal can never do, and secondly they show none of the physical properties of these crystals, but properties that are either identical with those of the hexagonal holohedral crystals, or are in the main of the same kind, differing only just so much as might be expected from the lower degree of symmetry they possess.

Just as hexagonal crystals are divided into a number of distinct classes, so also are the crystals of the other systems as far as their varying symmetry allows. Thus regular crystals are either (a) holohedral, (b) hemihedral, and that of three kinds, *viz.* tetrahedral, pentagonal, or plagioclinal, or (c) tetartohedral of one kind only; the quadratic crystals are subdivided exactly like the hexagonal ones; the rhombic crystals are either (a) holohedral or (b) hemihedral; and the monosymmetric and asymmetric crystals can show neither hemihedrie nor tetartohedrie.

There still remains another regularity met with in the forms of crystals, *viz.* the symmetrical growth of two or more crystals as one individual. Such a complex is called a *twin* or *trilling*, and in such the component individuals are definitely related as regards position, *viz.* the one crystal generally occupies such a position that were it rotated through  $180^\circ$  about a particular line, called the *twin axis*, all its faces &c. would then be exactly parallel to those of other crystals. The plane at right angles to the twin axis is called the *twin plane*, and in many instances the two individuals meet in this plane, and it is

then also termed the *contact plane*; but in other instances the two individuals penetrate each other in a perfectly irregular manner, and there is then no definite contact-plane. The formation of a twin crystal is probably explained by extreme viscosity of the solvent, or of an insufficient lapse of time between the separation of two molecules from a solution and their approximation to form a single solid particle, and for either of which reasons the molecules would not be able to become exactly parallel, which must be the most stable position, but would take up the next most stable position by reason of the molecule being originally more nearly in that position. As a plane of symmetry for the external form is also a plane of symmetry of the intermolecular force, which varies with the direction in which it is exercised, so a plane of symmetry can never be a twin plane, else the two individuals would be exactly parallel; that is, they would be identical: further, as the arrangement of the molecules, and consequently the external form, depends on this same intermolecular force, so the twin plane and axis are invariably connected with the external form; generally the twin plane is a possible crystalline face, and often one that is expressed by a very simple symbol. Twin or complex crystals are often characterised by re-entering angles, but these are frequently either so small as to be unnoticeable or are not present, and the crystal then affects a symmetry that it does not really possess.

The following figs. represent rhombic aragonite crystals; fig. 22, a simple crystal, and fig. 23,

FIG. 22.

FIG. 23.

a twin, showing re-entering angles, the twin plane being the prism face; and lastly, fig. 24 represents a

FIG. 24.

a trilling, showing only the forms (110) and (001), which externally appears very like a hexagonal crystal, except that two of the vertical faces are a little nicked because the angle of the prism (110) is not exactly  $120^\circ$ . The real nature of such compound crystals is most easily detected by their optical properties, a section cut parallel to the base at once resolving itself in a parallel beam of polarised light into a number of segments distinguished from each other by difference of colour or luminosity, and whose relative positions can readily be determined by optical examination.

Besides representing the form of crystals by parallel projections, as in the various figures, these forms are often also represented in a totally different manner, viz. by spherical projection. From a central point within a crystal, imagine a sphere of any radius described, and from its centre a line let fall perpendicularly on to every crystalline face and produced until it cuts the surface of the sphere. The positions of the faces are thus recorded by as many points upon the surface of the sphere, and their positions may very conveniently be represented upon a flat surface by making a diametral section of the sphere bringing the recording plane and one extremity of the diameter at right angles to that plane into the point of view, whereby great labour in drawing and calculating is saved, as all great circles on the sphere appear in the projection as straight lines or as arcs of circles. In the regular, hexagonal, and quadratic systems the diametral section is always drawn parallel to the plane of principal symmetry, in the rhombic system to the basal plane, in the monosymmetric and asymmetric systems it is drawn perpendicular to the faces of the prisms. Thus the beryl crystal, fig. 5, as far as the sphere lies in the plane of this paper, appears as in fig. 25, and the position of the three faces, when drawn upon the plane of principal symmetry, as in fig. 26; the one straight line joining the three

FIGS. 25 AND 26.

points shows that they are in the same zone, that is, are all parallel to one common direction, and therefore their intersecting edges are parallel, and this fact is very easily noticed or tested when the crystal is mounted on the goniometer for measuring. The completed projection appears as in fig. 27, where zones are all indicated by the various lines circular or straight. This method of projection also allows of the positions of optical axes, cleavage planes, &c., being shown.

It now only remains to mention a few points concerning the growth and actual appearance of

the faces of a crystal, beyond those mentioned on p. 278. A crystal once formed in a solution and continuing to increase in size, every face, or at least every face of any set of faces, would receive a deposit of the same thickness, and an ideally perfect crystal as represented in the figures would result, were it not that the liquid

FIG. 27.

in depositing the solid substance altered its specific gravity, and currents being thus generated different parts of the crystal are thus subjected to different conditions, and the several faces receive unequal deposits of new material. In consequence, the intersections of the similar faces and their superficial extent are often very dissimilar, though every face always remains exactly parallel to its original position, and the interfacial angles are constant. This so-called *distortion* is often brought about or increased by the crystal becoming attached by an end or side to other crystals, or to the containing vessel. Thus fig. 28 represents an alum crystal that has lain on the flat bottom of the containing vessel, and fig. 29 represents the ideal

FIG. 28.

FIG. 29.

form such as may be obtained by constantly changing the position of the growing crystal.

When new material is very quickly presented to a growing crystal, it is often noticed that the acuter solid angles grow extremely rapidly, shooting out into long needle-like points, and often other acicular points will start from along the first, and thus fern-like forms are produced; all such growths are termed *crystalline skeletons*; when the rate of deposit becomes less the needles almost cease to grow in the direction of their length, but increase continually in breadth and thickness until they touch each other, and the crystal returns to its original appearance, though almost invariably it will contain a great number of larger or smaller cavities, filled with the mother-liquor, and, as already mentioned, these cavities exhibit an arrangement or a form that corresponds with the general symmetry of the crystal. Some substances, as ammonium chloride,

metallic silver, &c., are very prone to form such dendritic forms, while with other substances, as platinum-potassium chloride, if existing crystals were not able to take up the new material, a multitude of minute crystals would at once form. The direction of these skeleton arms is always coincident with some crystallographic direction, and they are in reality made up of numerous crystals, in exactly parallel position. It has been mentioned that the faces of crystals are often striated; the striae consist of numerous alternating faces of one or more forms; thus nitre crystals are vertically striated on the prism and pinacoid faces by reason of these faces being repeated alternately very many times.

Finally it may be useful briefly to describe such a microscope as is used for the examination of minute or growing crystals, or for the examination of rock sections. In this connexion reference should be made to the papers of Behrens (*Royal Micros. Soc. Journ.*, 1882) and others, on the microchemical reactions by which minute fragments of minerals &c. may be analysed qualitatively by converting their constituents into crystalline precipitates that may be recognised under the microscope. The essential parts of the microscope are the same as in every other instrument, the parts specially concerned in crystallographic work being the following. The stage can be rotated freely about the optical centre of the instrument, and is brought exactly into that position by a couple of adjusting screws; the circumference is graduated into degrees, and fractions can be read by a vernier. The eye-pieces contain crossed (rectangular) threads, and these always occupy a fixed position by reason of a pin in the eye-piece and a notch in the outer tube. Plane angles of crystals that lie suitably, the angles between the lines of inclosures &c., are easily measured by the rotating stage and the cross of the eye-piece. The fine adjustment-screw for focussing is of known pitch, and is provided with a head divided on its circumference. By using a high power and a rather thick specimen it is easy to determine the refractive index not only of solids but of liquids (Sorby). In the eye-piece can be fitted a micrometer scale, and by using this and the micrometer screw the interfacial angles of minute crystals can be measured, though the method is one that would only be used if the goniometric measurement were not possible. During the cutting or grinding of sections, especially rock sections, the crystals often cleave, and the positions of the planes of cleavage are at once determined from the fine parallel hair-like cracks in the specimen. Underneath the stage a polarising prism is quickly put into position so that its polarising plane is parallel to one of the cross threads in the eye-piece; crystals may then be examined for dichroism. Above the stage, and most conveniently over the eye-piece, a second polarising prism may be placed or rapidly removed; it may be rotated about the central axis, and the amount of rotation is approximately shown on a small divided circle. When the two prisms are crossed, isotropic and anisotropic crystals are at once distinguished, unless the crystalline plate is at right angles to the optical axis, but in this case the interference figure can be obtained as described below; further, if the crystal be anisotropic,

twinning is generally at once recognised, and, with the help of the rotating stage, the relationships of the different parts are determined, by comparing the depolarising directions among themselves and with the edges of the crystal; similarly in a simple anisotropic crystal the angles between the depolarising directions and the edges may be measured, and the system of crystallisation thus determined when the examination of the external form alone would not have been conclusive; and even when the external form has been destroyed, or when it has been lost by reason of the crystal growing until it filled the whole space that happened to be at its disposal, the examination of the cleavage cracks, lines of inclosures, and depolarising directions, is often sufficient to determine the crystalline system. The relationship between depolarising directions and edges may be used for discriminating between different substances crystallising in the monosymmetric or asymmetric systems, as the various feldspars. Finally anisotropic crystals lying in suitable positions can be examined for their interference figures by removing the eye-piece, but retaining both polarising prisms, placing a small, very short, focus-lens above the lower prism and directly below, but quite close to, the crystal, and lastly using a short focus objective and bringing it down rather close to the specimen. The interference figures thus observed are certainly very small, and an extra lens is sometimes inserted above the objective to magnify them, but the angle of view is thereby diminished. Uniaxial and biaxial crystals are thus at once distinguished, and if the former show any marked amount of circular polarisation, or the latter any marked amount of dispersion for the various colours, these phenomena can also be noticed, especially if use is made of red and blue glasses to simplify the phenomena; such glasses are also used in the measurement of the angles between depolarising directions and crystalline edges. H. B.

**CUBEBS.**—The fruit of *Piper Cubeba*, a native of Java. It contains a volatile oil (from which 'camphor of cubebs' may be separated), a crystalline substance cubebin, an acid resin cubebic acid, and an indifferent resin (Monheim, *J. chim. Méd.* 11, 352; Blanchet a. Sell, *A.* 6, 294; Müller, *A.* 2, 90; Winckler, *A.* 8, 203; Soubeiran a. Capitaine, *A.* 31, 190; 34, 311; *J. Ph.* 26, 75; Auborgier, *Rev. Scient.* 4, 220; Schmidt, *Ar. Ph.* [2] 191, 1; Schær a. Wyss, *Ar. Ph.* [3] 6, 316; Ogialoro, *G.* 5, 467).

**Oil of Cubebs.** Contains dipentene, the hydrochloride of which  $C_{10}H_{16} \cdot 2HCl$  melts at  $49^\circ$ , but consists chiefly of hydrocarbons boiling between  $250^\circ$  and  $270^\circ$ , amongst which is a sesquiterpene  $C_{15}H_{24}$  ( $275^\circ$ ). V.D. 6.73 (calc. 7.05), whose hydrochloride  $C_{15}H_{24} \cdot 2HCl$  melts at  $118^\circ$  (Wallach, *A.* 238, 80) or  $[131^\circ]$  (S. a. C.F. [118]).

**Camphor of Cubebs**  $C_{15}H_{24}O$ . ( $87^\circ$ ). ( $148^\circ$ ). Occurs only in old cubebs. Trimetric crystals (from alcohol-ether). Lævrotatory. At  $230^\circ$  it is split up into water and cubebene  $C_{15}H_{24}$  (Schmidt, *B.* 10, 189; cf. Berthelot, *Bl.* [2] 11, 3).

**Cubebin**  $C_{10}H_{16}O_2$ ,  
i.e.  $[4.1] CH_2 \begin{array}{c} \diagup O \\ \diagdown O \end{array} C_6H_8(C_2H_5O)?$  ( $125^\circ$ ). S. (alcohol) 1.31 at  $12^\circ$ . S. (ether) 3.75. Extracted by alcohol from cubebs after removal of the

essential oil by steam distillation (Schuck, *N. Repert. Pharm.* 1, 213; Steer, *A.* 36, 331; Weidel, *Sts. W.* 74 [2] 377; Schär, *Ar. Ph.* [3] 25, 531).

**Properties.**—Small needles (from alcohol); v. sl. sol. water. Conc.  $\text{H}_2\text{SO}_4$  colours it crimson.  $\text{HCl}$  and  $\text{HI}$  have no action on it.

**Reactions.**—1.  $\text{KMnO}_4$  on warming oxidises it to oxalic acid and a resin, from which, after extracting with  $\text{CHCl}_3$ , a crystalline residue of piperonylic acid  $\text{C}_{10}\text{H}_8\text{O}_4$  [228°] is obtained.—2. When heated with *acetic anhydride* and *sodium acetate* to 140° C. it yields  $\text{C}_{10}\text{H}_8\text{O}_4$  [78°], which can be obtained pure by crystallisation from alcohol (Pomeranz, *M.* 8, 466).—3. *Potash-fusion* gives  $\text{CO}_2$ ,  $\text{HOAc}$ , and protocatechuic acid.—4.  $\text{HNO}_3$  gives oxalic and picric acids.—5. *Nitrous acid* gives yellow crystals of nitro-cubebine  $\text{C}_{10}\text{H}_8(\text{NO}_2)_2\text{O}_4$ , which dissolves in aqueous  $\text{KOH}$ , forming a violet solution.—6. Br, added to a solution of cubebine in chloroform, gives  $\text{C}_{10}\text{H}_7\text{BrO}_4$ , which separates from boiling xylene in white crystals.

**Benzoyl derivative**  $\text{C}_{10}\text{H}_8\text{BzO}_2$ . [147°] (Pomeranz, *M.* 9, 323).

Cubebic acid  $\text{C}_{10}\text{H}_8\text{O}_4$  (Schulze, *Ar. Ph.* [3] 2, 388);  $\text{C}_{10}\text{H}_8\text{O}_4$  (Schmidt, *Ar. Ph.* [2] 191, 1). A resinous acid extracted from cubebis by ether, freed from volatile oil by steam-distillation, and purified by re-crystallisation of its Ba salt (Bernazik, *C.* 1864, 191). Amorphous, insol. water and acids, v. sol. alcohol, ether, and alkalis.

**CUDBEAR.** A name given to a variety of archil, being also prepared from lichens, chiefly of the genus *Lecanora*.

**CUMALIC ACID** v. COUMALIC ACID.

**CUMARYHYDRIN** v. COTO BARK.

**$\psi$ -CUMENE**  $\text{C}_9\text{H}_{10}$  ( $\text{CH}_3$ )<sub>2</sub> [1:3:4]. *t*-Tri-methylbenzene. Mol. w. 120. (169.4° i.v.) (Jacobsen, *B.* 19, 2513). S.G.  $\frac{2}{4}$  8043;  $\frac{22}{4}$  8530. H.F.p. 1810. H.F.v. -1690 (Th.). Dielectric constant 2.431 at 14° (Negreano, *C. R.* 104, 423).  $\mu_D$  1.454. Occurs in all kinds of petroleum (American, Russian, &c.) (Engler, *B.* 18, 2234; cf. Mansfield, *C. J.* 1, 244; A. 69, 179; Ritthausen, *J. pr.* 61, 79; Beilstein & Kögler, *A.* 137, 317).
